THE

ENGLISH CYCLOPÆDIA.

ARTS AND SCIENCES.

O, in the vowel series, if arranged according to the nature of the sound, occupies the position between *a* and *u*. In the hieroglyphical characters it appears, according to Champollion, to have been a picture of an eye, and even in the old Greek alphabet it is occasionally found with a dot in the centre, to represent the pupil, for instance in the Elean Tablet. But for the different forms of the letter see ALPHABET. The changes to which this vowel is liable are numerous.

1. It is convertible with the adjoining vowel *u;* and indeed the two characters seem to have had a common origin. Thus, the old Greek alphabet would appear to have once terminated, like the Hebrew, with *tau*, so as to exclude the *upsilon;* whereas the Etruscans had a *u* but no *o*. Hence the predominance of the *o* in Greek, of the *u* in Latin. Within the limits of the Latin itself the two letters are often interchanged, out of which arises the confusion between the second, or *o*, and the fourth, or *u* declension, to both of which belong *ficus, cibus, senatus, tumultus, ornatus, laurus, domus*, &c. The words *consul* and *consulere* also appear as *cosol* and *cosolere*, and they have both a common root with *solium*, a seat.

The English language, too, has often an *o* written where *u* is heard, as *one, none, once, come, done, won, some*.

2. With *a*. Grimm has pointed out this change as existing between the Latin and Teutonic tongues, as *doma-re, longus, odium*, &c., compared with *zähm-en, lang, hass*, &c. Hence, too, the double form of the name *Longobardi* and *Langobardi*. So, in Latin, from the root *gno* (*gnosco*) were formed *gnarus* and *ignarus:* and again, from these *narrare* and *ignorare*, in the latter of which the original vowel reappears. Again, with *clarus* is connected *gloria*, as closely as *gratia* with *gratus*. It is probable too that the masculine *bono* and the feminine *bona* were mere dialectic varieties which originally had no distinction of gender. Thus in the Gothic the converse prevails, the forms in *o* being feminine, those in *a* masculine. Lastly, the English and Scotch have many instances of the interchange, as *one, two, stone*, in the one, *ane, twa, stane*, in the other; but perhaps this change belongs to the next head.

3. With the long *ē*, the sound of which must be considered as the same with the English *a*. Hence in Greek, Ευπατωρ, *απατωρ*, &c., from *πατηρ*; and the Latin *sol, cor* correspond with the Greek *ἥλιος*, and *κηρ* (observe too the German *herz*). The town *Nemetum* in Gallia is called by Greek geographers Νεμωσσος, and the German *jener* is in English *yon*.

4. With *ou*. This interchange is virtually the same with the first-mentioned. It is not uncommon in French, as compared with Latin, as *novella, nouvelle; rota, roue; totus, tout*, &c.

5. With *uo*, especially in Italian, as *huomo, buono, luogo, nuovo*, from the Latin *homo, bonus, locus, novus*.

6. With *eu*, in French, as *lieu, feu, jeu, peu, leur, heure, douleur, queue;* from the Latin, *locus, focus, jocus, pauci* (and Italian, *poco*), *illorum, hora, dolor, cauda*, or *coda*.

7. With *au*. This exists within the Latin; as *cauda* and *coda, cautes* and *cotes, caudex* and *codex, Claudius* and *Clodius, plaudo* and *plodo*. So from the Latin *aurum, audere* (whence the frequentative *ausare*), *Aufidus, audire*, the Italians have *oro, osare, Ofanto;* and the French *or, oser, ouir*. Hence too the French pronunciation of the diphthong *au*.

8. With *oa*. Thus, the English words *boat, oath, oak*, must have received their present orthography when both the vowels were pronounced, as they still are in some parts of England, *bo-at, o-ath*, or *boo-at, oo-ath*.

9. With *ue*, as in the Spanish *bueno, luego, fuego, huesped;* from the Latin *bonus, locus, focus, hospes*.

10. An initial *o* with *hue* or *hui*. Hence from the Latin *ostium, ostiarius*, are derived the French *huis, huissier*, and the English *usher*. From the Latin *os*, a bone, *ovum* an egg, the Spaniards have *hueso, huevo*. From the Latin *octo, ostrea*, come the French *huict* or *huit, huistre* or *huître*. From the Latin *hodie*, which appears to have been pronounced as the Italian *oggi*, was formed the French *hui*, in *au-jour-d'-hui*.

11. In the paragraphs numbered 5, 9, and 10, the *o* really takes the sound of the English *w*, or the Greek digamma; and the same is the case in the Greek language itself, as in *οικος, οινος, οιδα*, Οαξος (which is the true reading in Herodotus, iv. 154), for Fικος, Fινος, Fιδα, Fαξος; the first three of which may be compared with the Latin *vicus, vinum video*. Closely allied hereto is the frequent interchange in Latin of *oe* or *oi* with *ū*. [U.]

12. With *ea*, as between German and English. Thus the former language has *strom, brot, gross, tod, drohen;* the latter *stream, bread, great, death, threat*. This same change exists in the English by itself, as *cleave, clove; weave, wove; heal, whole; heat, hot*, &c.

13. With *ei*, pronounced as the English long *i*. This is exceedingly common in the same languages. Compare the German *beide, bein, ein, nein, geist, heim, heiss, kleiden, mannheit, meist, theil, heilig, reihe, speiche, zeichen;* with *both, bone, one, none, ghost, home, hot, clothe, manhood, most, dole, holy, row, spoke* of a wheel, *token*. This change also exists within the English language, as *shine* and *shone; strike* and *stroke; drive* and *drove*.

14. A short *ŏ* with a short *ĕ*. This is particularly common in Greek, and above all in the penult of disyllables. Thus with *νεμω, στελλω, λεγω*, there co-exist the substantive forms *νομος, στολος, λογος*. The Latin commonly prefers the *ŏ* in such words. Hence to the Greek *πεπτω, επι, εννεα* (*εννεFα*), *νεος* (*νεFος*), *εμεω* (*Fεμεω*), correspond the Latin *cŏquus* and *pŏpina, ŏb, nŏvem, nŏvus. vŏmo*. The change of these vowels is exceedingly common when preceded by a *w* sound, especially if an *r* or *l* follow. Hence in Latin, *verto* and *vorto, velle* and *vŏlo, vester* and *voster, vĕto* and *vŏto*. Hence likewise to the Latin *vermis, vellus, verruca*, correspond the English *worm, wool, wart*. Again the German *schwerdt* is in English *sword;* and *vice versâ* the German *ant-wort* is in English *answer;* and lastly, many words of this form are written with an *o* and pronounced with an *e*, as *wort, worm, worth, worse*.

15. For the tendency of the final letter *n* to disappear after *o*, see N.

OAK, ECONOMICAL USES OF. The oak subserves a greater number of useful purposes than almost any other kind of forest tree. All things considered, British oak is more durable than any other timber largely grown in Europe; and hence its enormous employment in the arts. The wood is hard, tough, tolerably flexible, strong without being too heavy, not easy to splinter, and not readily penetrated by water. An experiment once showed that a weight of 10,000 lbs. was required to break an oaken beam 11 feet long by 5 inches square. With twisted grain the wood is admirably suited for posts for houses, mills, engines, and large machines. It bears alternations of wet and dry better than most other woods; oak piles have been known to endure for many centuries. It is excellent for shingles, pales, laths, and casks. The small slow-growing variety is much employed for the spokes of wheels. The young tree yields slender rods, well suited for hoops, walking sticks, and the handles of carters' whips. The great durability of

British oak is illustrated by numerous well-known examples; such as some of the doors, Edward the Confessor's shrine, and the Coronation chair, at Westminster Abbey; fragments of King John's palace at Eltham; the Plantagenet stalls of Gloucester Cathedral; the piles of the old Savoy palace; the piles beneath the buttresses and starlings of Old London Bridge; the wooden church near Ongar; and Cowey stakes near Oatlands,—which were applied to their respective uses at periods varying from five to nineteen hundred years ago. More important, however, than any of these uses of British oak, is its employment in ship-building, with which it is associated in song and metaphor as well as in fact. An oaken vessel or boat, perfectly sound, and nearly as hard as iron, was found a few years ago in the bed of the river Rother, in Kent, where it is supposed to have lain since the time of Alfred the Great. For more than a thousand years British ships have been mainly built of British oak. During the great wars of 1793 to 1815, the consumption was enormous. In 1806 it was calculated that the ships of the navy contained nearly 1,200,000 loads of timber; and that 100,000 loads a year would be required to keep up the strength, by renewals and repairs. It requires 50 acres of land, and about 100 years in time, to grow oak timber sufficient for one 74-gun ship; a fact that will illustrate the value of old forests to our ship-yards. The royal forests of England either do not contain oak trees enough for national use, or they are too badly managed to yield the supply when wanted. As a consequence, large purchases are made nearly every year. A parliamentary return, called for a few years ago, showed that in eleven years (1840 to 1850 inclusive) the average purchase of British oak for the royal dockyards was nearly 9000 loads, varying from 3000 to 20,000 in a year. There are other varieties of oak, besides the British, which yield timber useful for many purposes in the arts. Turkey oak is not so strong and durable as British, but as its grain is more beautiful, and takes a better polish, it is available for ornamental purposes. The American white oak is much used for ship-building and house building, for cask staves, for milk pails, axe handles, &c.; while the wood of the young trees, being very elastic, and susceptible of easy division, is used for many of the purposes of willow, bamboo, or whalebone, in the making of baskets, brooms, chair seats, riddles, and carters' whips. The live oak, or *quercus virens*, is very largely used in the United States for ship-building; it is strong and durable, though in some degree unfavourable on account of its great weight; it is found, also, to be far better than the white oak for the naves and felloes of heavy wheels, and the screws and cogs of mill-wheels. There are other varieties of American oak, used for a great number of purposes, but none equal to British oak for strong and durable timber.

Every part of the oak tree comes to use. The bark is a more valuable tanning agent than any other known substance; and even the leaves and the saw-dust contain an astringent principle which is applicable to the same purpose. The Valonia oak of the Archipelago yields those acorns and cups which constitute the valuable tanning ingredient called *valonia*. The Dyer's oak is the kind which yields the dye-drug, *quercitron bark*. It is from a species of oak, the *quercus liber*, that we obtain that remarkable bark, *cork*, which is so superior to all other substances for the particular purposes to which it is applied. The scarlet dye, called *kermes*, is obtained from an insect which feeds upon one particular sort of oak to which it forms a kind of parasite, clinging to the branches. The black-dye drug *nut gall* is a morbid excrescence, produced by the puncture of a winged insect, in a small species of oak called the *quercus infectoria*. What is called the *oak apple* is a somewhat similar excrescence on the British oak, applicable to the same purposes as the nut gall, but not in so great a degree.

The root of the oak was formerly carved into knife and dagger handles, tobacco boxes, and small implements and instruments of various kinds. It is now frequently cut into veneers, which present a beautifully diversified surface when polished. Oak leaves, gathered green and dried, furnish in some places a winter forage for sheep, deer, and goats. In ordinary gardening, they sometimes serve as a substitute for tanner's bark, in maintaining the heat of hothouses, &c. The acorns of the oak are a valuable produce of our forests. Evelyn used to say, that a peck of acorns with a little bran will increase the weight of a hog a pound per day for two months together; and even if this be a high estimate, it leaves untouched the truth that acorns form an excellent hog-fodder. Acorns form an important part of the food of deer in many English parks. Poultry will eat acorns, raw or boiled.

OAK-BARK. [Bark.]

OAKUM. When the various cables, stays, shrouds, ropes, &c., belonging to a ship have gone through their term of service, and are no longer strong enough to be used, they are cut up into pieces, and then pulled asunder, all the hempen threads being loosened and disentangled one from another. In this state the hempen threads are called *oakum*, which varies in quality according to the kind of rope from which it is produced. The old ropes of a ship are sold to dealers; and when picked into oakum they are again sold to ship-builders. The work of oakum-picking is a kind of forced employment in many prisons. The oakum is sold to the ship-builders in large bundles, and is then spun into loose threads. These threads are of a very primitive kind; a small bundle of fibres is rolled by the hand on a sloping board, till it assumes the form of a loose irregular kind of rope, from half an inch to an inch in thickness. These oakum ropes are used for driving into the crevices or seams in the outside or deck of a ship, to prevent the entrance of sea-water. This process is called *caulking*, and is effected by the aid of a large mallet or hammer and a caulking chisel; by which a dense layer of oakum is forced into the crevice—afterwards to be well tarred. If this process be well conducted, the ship's side is not only rendered waterproof, but is actually strengthened; for every little fissure becomes filled up with a substance little less compact than the timber itself.

OASIS (in Greek, Ὄασις, and sometimes Αὔασις) is the appellation given to those fertile spots watered by springs and covered with verdure which are scattered about the great sandy deserts of Africa. [Desert.] In Arabic they are called wadys. The Arabic and the Greek name seem to contain the same root, and possibly the word may be originally a native African term. The most noted oases are in the Libyan desert, namely Augila, Siwah, the great oasis west of Thebes, or El Khargeh, the little oasis, or Wah el Bahryeh, and several smaller ones which are noticed under Egypt, in Geog. Div. Fezzan also may be considered as a great oasis of the Sahara. [Fezzan; Sahara, in Geog. Div.]

The oases appear to be depressions in the table-land of Libya. On going from the Nile westward, the traveller gradually ascends till he arrives at the summit of an elevated plain, which continues nearly level, or with slight undulations, for a considerable distance, and rises higher on advancing towards the south. The oases are valleys sunk in this plain, and when you descend to one of them you find the level space or plain of the oasis similar to a portion of the valley of Egypt, surrounded by steep hills of limestone at some distance from the cultivated land. The low plain of the oasis is sandstone or clay, and from this last the water rises to the surface and fertilises the country; and as the table-land is higher in the latitude of Thebes than in that of Lower Egypt, we may readily imagine that the water of the oases is conveyed from some elevated point to the south, and being retained by the bed of clay, rises to the surface wherever the limestone superstratum is removed.

OATH. Oaths have been in use in all countries of which we have any exact information, and it is probable that there is no nation which has any clear notion of a Supreme Being, or of superior beings, that does not make use of oaths on certain solemn occasions. An oath may be described generally as an appeal or address to a Superior Being, by which the person making it engages to declare the truth on the occasion on which he takes the oath, or by which he promises to do something hereafter. The person who imposes or receives the oath, imposes or receives it on the supposition that the person making it apprehends some evil consequences to himself from the Superior Being, if he should violate the oath. The person taking the oath may or may not fear such consequences, but the value of the oath in the eyes of him who receives or imposes it consists in the opinion which he has of its influence over the person taking it. An oath may be taken voluntarily, or it may be imposed on a person under certain circumstances by a political superior; or it may be the only condition on which the assertion or declaration of a person shall be admitted as evidence of any fact.

The form of taking the oath has varied greatly in different countries. Among the Greeks (with whom the uplifted hands as if in prayer and the solemn sacrifice and libation marked the religious element, while the placing the hands on the victims or the altars reminded all parties that the deity himself was present, Iliad iii., 276, and iv., 158; Aristoph., Acharn, 148; Thucyd. v., 47) the forms of oaths were almost as various as the occasions. Oaths were often used by them in judicial proceedings. The Dicastæ, who were judges and jurymen, gave their verdict upon oath. The Heliastic oath is stated at length in the speech of Demosthenes against Timocrates (c. 36). It does not appear that the oath was always imposed on witnesses in judicial proceedings; and yet it does appear that sometimes witnesses gave their evidence on oath: perhaps the oath on the part of witnesses was generally voluntary. (Demosth., Πρὸς Ἄφοβον Ψευδ, c. 16; Κατὰ Κόνωνος, c. 10; Meier and Schömann, 'Att.' Process., p. 675, and Smith's 'Dict. of Gr. and Rom. Antiq.,' arts. Oath (Greek), and Μαρτυρία.)

In the Roman jurisprudence an oath was required in some cases from the plaintiff or the defendant, or both. Thus the oath of calumny was required from the plaintiff, which was a solemn declaration that he did not prosecute his suit for any fraudulent or malicious purpose. The offence of false-swearing was *perjurium*, perjury; but it was considered a less offence in a party to a suit when the oath was imposed by a *judex* than when it was voluntary. It does not appear that in civil proceedings witnesses were necessarily examined on oath; but witnesses appear to have been examined on oath in the judicia publica, which were criminal proceedings. (D. 12. 2. C. 1. 1. Brissonii and Calvini Lexic. 'Juramentum;' Bonnier, 'Traité des Preuves,' §§ 338-378.)

The law of England, as a general rule, requires all evidence or testimony for judicial purposes to be given on oath, and all persons may be sworn as witnesses who, being questioned on the occasion of taking the oath, will declare their belief in the existence of God, in a future state of rewards and punishments, and who will further declare their belief that perjury will be punished by the Deity. This rule permits all persons, of all religious persuasions, who profess to have the necessary belief, to be sworn as witnesses; and it excludes all other persons from being witnesses. A Jew, a Mohammedan, and a Hindu may be sworn as witnesses, but they must severally take the oath in that form which is sanctioned by the usage of their country or nation, and which they severally consider to be binding. (Omichund *v.* Barker; Willes's 'Rep.' 541, and 1 Smith's 'Leading Cases.') It follows that a person who avows atheism, or who does not profess such belief as is stated above, cannot be sworn, and consequently cannot be admitted to give testimony for judicial purposes. Children also who are too young to understand the nature of an oath, and adults who are too ignorant or too weak in intellect to understand what is meant by an oath, cannot be sworn as witnesses. The offence of declaring what is false, when a witness is examined upon oath, constitutes perjury: the particular circumstances which must concur in order that false-swearing shall be legal perjury are stated under that head. [PERJURY.]

Declarations made by a person under the apprehension of immediate death are generally admitted as evidence in judicial proceedings, when properly verified, "for the general principle," says Eyre, C.B., "upon which evidence of this kind rests is, that it is of declarations made in extremity, when the party is at the point of death, and when every hope in this world is gone, when every motive to falsehood is silenced, and the mind is induced by the most powerful considerations to speak the truth." A situation so solemn and awful is considered by the law as creating an obligation equal to that imposed by an oath in court. (1 Leach, 502; see also Alderson's remarks in Ashton's case; 2 Lewin, CC. 147). Quakers also, in all civil cases, were allowed by the statute 7 & 8 Wm. III., c. 34, to give their evidence on affirmation; and now the affirmation of Quakers, Moravians, Separatists, and others who having been Quakers or Moravians conscientiously object to taking oaths (3 & 4 Wm. IV., c. 49, and c. 82; and 1 & 2 Vict., c. 77), is admissible in all judicial proceedings, both civil and criminal. (See also 17 and 18 Vict., c. 125, s. 20.) When a defendant in chancery is entitled to privilege of peerage, or as a lord of parliament, he is required to give his answer to a bill upon honour only; and in the case of a corporation, the corporate body defendants put in their answer under their common seal. Other defendants are required to put in their answer upon oath. For other matters connected with judicial evidence, see EVIDENCE.

An oath is required in England in a great many cases besides judicial proceedings, as for instance, on admission to places of public trust, and on a variety of other occasions.

As oaths may be either voluntary or may be imposed by a political superior, so they may be imposed either on extra-judicial or on judicial occasions. Oaths which are imposed on occasion of judicial proceedings are the most frequent in this country, and the occasions are the most important to the interests of society. The principle on which an oath is administered on judicial occasions is this: it is supposed that an additional security is thereby acquired for the veracity of him who takes the oath.

There are occasions on which oaths are treated lightly, on which he who imposes the oath, he who takes it, and the community who are witnesses to it, treat the violation of it as a trivial matter. Such occasions as these furnish Bentham with arguments against the efficacy of oaths on all occasions. Suppose we admit, with Bentham, as we do merely for the sake of the argument, that "on some occasions oaths go with the English clergy for nothing;" and this, notwithstanding the fact, which nobody can doubt, "that among the English clergy believers are more abundant than unbelievers." The kind of oaths "which go for nothing" are not mentioned by Bentham, but they may be conjectured. Now, if all oaths went for nothing with the clergy, or with any other body of men, the dispute would be settled. But this is not the fact. If in any way it has become the positive morality of any body of men that a certain kind of oath should go for nothing, each individual of that body, with respect to that kind of oath, has the opinion of his body. He does not believe that such oath, if broken, will bring on him divine punishment, and therefore such oath *is* an idle ceremony. But if there is any oath, the violation of which he thinks will bring on him divine punishment, his opinion as to that kind of oath is not at all affected by his opinion as to the other kind of oath. Now, oaths taken on judicial occasions are by the mass of mankind considered to be oaths of the latter kind, and therefore they have an influence on the great majority of those who take them. Whether society will in time so far improve as to render it safe to dispense with this ceremony in judicial proceedings, cannot be affirmed or denied; but a legislator who knows what man now is, will require better reasons for the abolition of judicial oaths than Bentham has given. For some able remarks on this part of the subject, the reader is referred to Mr. Best's admirable treatise on the 'Law of Evidence,' 3rd edit., pp. 61-67.

How far the requisition of an oath may be injurious in excluding testimony in certain cases, and how far oaths on solemn and important occasions may be made most efficacious, and in what cases it may be advisable to substitute declarations in lieu of oaths, are not matters of consideration here. It is enough here to show that an oath is a sanction or security to some extent, if the person who takes it fears divine punishment in case he should violate it; and that this, and no other, is the ground on which the oath is imposed.

Indeed it is evident that in English procedure the professed opinion or belief of the person who takes the oath is the only reason for which courts of justice either admit or refuse to receive his evidence; and this is shown by the questions which may be put to a witness when he comes to deliver his evidence in a court of justice. (See L. C. J. Willes's judgment in Omichund *v.* Barker, Willes, 541.)

There is some difficulty in stating accurately how far oaths were required from witnesses in Roman procedure under the republic and the earlier emperors. In addition to what has been stated, the reader may refer to Cicero, 'Pro Q. Rosc. Comoed.,' c. 15, &c.; Noodt, 'Op. Omn.,' ii. 479, 'De Testibus;' to the commentary of Asconius on the Verrine Orations; and to Zimmern's treatise on 'Civil Procedure among the Romans,' §§ 135 & 150. By a constitution of Constantine, all witnesses were required to give their testimony on oath; and this was again declared by a constitution of Justinian. ('Cod.' 4, 20, 9. 16. 19.)

Many persons conscientiously object to the taking of an oath on religious grounds, and particularly with reference to our Saviour's prohibition (Matth., v. 33). On the subject of oaths in general the reader may consult Grotius, 'De Jure,' B. & P., lib. ii., c. 13; Paley's 'Moral Philosophy;' Tyler's 'Origin and History of Oaths;' the 'Law Magazine,' vol. xii.; and the work of Bentham already referred to.

OATS (*Avena sativa*) is a well-known species of the genus *Avena*, a plant of the family of the *Gramineæ*. [AVENA, in NAT. HIST. DIV.] We shall here only consider those varieties which are cultivated for their grain, principally as food for horses, and in some cases for men also, when ground into oatmeal or grits.

The great use of oats, and the ease with which they are raised on almost every kind of soil, from the heaviest loam to the lightest sand, have made them occupy a place in almost every rotation of crops. Before agriculture had been subjected to regular rules, the result of long experience, the land was often sown as long as any return could be obtained, before any means of recruiting it with manure were thought of; and the last crop which would return any increase of the seed was generally oats. After this, the land, no longer repaying the labour of ploughing and sowing, was abandoned, till, by length of time, by the decomposition of roots and weeds, and the replenishment by the action of atmospheric solvents of the store of inorganic matter in a soluble condition, some renewed fertility was produced. The exhausting character of the plant is to some extent explained by the quantity of mineral matter removed from one acre by an ordinary crop of, say 48 bushels: 96 lbs. of soluble silica, 23 lbs. of phosphoric acid, and 36 lbs. of potash are thus taken from the land. Some farmers, on account of the exhausting character of the crop, prefer buying all their oats in the market to raising them on their own land. Where the soil is well adapted to the growth of wheat and barley, which bear a better price, this may be a judicious plan; but as a general rule, it is always more profitable to raise oats for home consumption than to trust to a fluctuating market. With proper management, a crop of oats may give as great a profit on the best land as any other crop, when it is considered that it requires less manure and produces an abundance of straw, which is very fit for the winter food of horses and cattle, especially when aided by roots or other succulent food. There are nearly 2,000,000 acres of oats grown annually in Ireland, nearly 1,000,000 acres in Scotland, and probably 1,250,000 acres in England. This is four times as much as of wheat in Ireland, four times as much as of wheat in Scotland, and one-third as much as of wheat in England. The colder climate of the two former districts over the greater part of their surface is what makes the oat the more prevalent crop.

The best oats are raised in Scotland and in Friesland, and in both countries the land is carefully cultivated. In Scotland, oats are generally sown on a grass layer which has been in that state for some years, and sometimes on old pastures which are broken up for the purpose. The crops exceed in bulk and weight of grain all that the most sanguine person, unacquainted with the system, would expect, and in many seasons, not favourable for the wheat crop, oats are much more profitable. Wherever the land is not of a good quality, and wheat is apt to fail, oats are a much safer crop, especially in retentive soils, as rye is on poor sands.

When oats are sown after turnips, cabbages, or any other green crop, the land should be well ploughed, if the green crop was not consumed on the spot, and a moderate supply of manure will be well repaid by the increased produce. A heavy loam is best suited for oats: they require a certain degree of moisture, and a deep soil is very favourable to their growth. On land which has been trenched, or where the subsoil plough has been used, after careful draining if required, oats will thrive wonderfully, without requiring so rich a soil as barley or wheat. The roots are hardier and have a stronger vegetative power. When once they have struck deep into the soil, a good crop, according to the quality of the land, may be relied on.

When oats are sown after artificial grasses, the land is seldom ploughed more than once, and the seed is sown on the fresh mould which has been turned up; but unless the land be very free from weeds, it would be better to plough the sward with a shallow furrow early in autumn. Before winter the scarifier would break the rotten sward, which might then be buried deep by another ploughing. The land would be ready for sowing early in spring, which is a great advantage, both as to the quality of the oat crop and the earlier harvest, especially in those districts where the latter part of the autumn is apt to be stormy and rainy. The land thus treated would be clean, and the fallow, which is often resorted to of necessity after a crop of oats, might be dispensed with, as the weeds have been destroyed and buried deep.

When oats are sown on light land after turnips, which have been eaten by sheep folded on them, it may be ploughed with as shallow a furrow as will turn in the surface: the preparation for turnips will have sufficiently moved the soil; and the manure of the sheep should not be buried too deep. On poor moist land oats are more profitable than barley. Clover and grass seeds may be sown among them with equal advantage, as they will seldom grow so high as to be laid and smother the young clover; and barley is very apt to fail on land subject to retain the water.

In sowing oats more seed is often used than of any other grain, because, although the plants tiller where they have room, the straw of the second shoots is weaker, and the grain is not ripe so soon as that of the principal stem; but when the plants rise close and thick, there are no tillers, the main stem is stronger, and the corn is more plump and equal. Six bushels of oats are often sown in Scotland and Ireland on an acre; but if they are drilled, three or four bushels are sufficient, and when dibbled, which is sometimes the case in Norfolk and Suffolk, much less seed is used. A good preparation of the land is of more consequence than a superabundance of seed.

In a field where oats are sown broadcast, and covered by the harrows, many seeds remain exposed to the depredation of birds, which soon find them out at a time of the year when food is scarce; but when they are drilled or dibbled, all the seed is buried and germinates, without any loss. When the seed is sown and ploughed in, the same object is attained; but as the furrow must be shallow in order that the seed may not be buried too deep, the land must have been ploughed before to a considerable depth, unless it be after turnips fed off by sheep, in which case ploughing the seed in is often considered a good practice: in either case four bushels of seed per acre is an ample allowance.

When the ground has been well prepared, there is no necessity for weeding or hoeing the crop as it advances; but if large weeds appear, such as charlock, May-weed, docks, or thistles, they must be carefully weeded out, or else the ground will be so infested with their seeds or roots that it will be difficult to eradicate them afterwards. Oats, when fully ripe, are very apt to shed, and many are lost for want of attention. As soon as the straw turns yellow under the panicle, the oats should be reaped, however green the lower part of the straw may be; the straw will be better fodder for cattle, and all the corn will be saved. Oats are generally mown with a scythe, and raked into heaps to dry like hay; but this is a wasteful and slovenly practice. A good crop of oats should be reaped, like wheat, close to the ground, and tied in sheaves. This may now be done perfectly by machine; but if by hand, the scythe, or the heavy hook, or the Hainault scythe, does the work well in the hands of an expert mower, who should be followed by binders, who gather the straw with their hands and lay it regularly on the ground if it be not fit to tie up immediately: the straw should afterwards be tied up into sheaves, and set with the corn uppermost in shocks of ten or twelve sheaves, leaning against each other, and open at bottom, in order to allow the air to pass through. Thus, in a short time the oats become sufficiently dry to be stacked, or carried immediately into the barn. The produce of an acre of oats varies according to the soil and preparation, from four to eight and even ten or twelve quarters.

Of the many varieties of oat now in cultivation, the "Poland" may be named for its early habit and good quality; the "Potato" oat for quality and productiveness; the "Hopetoun" and "Sandy" oats for their bulky growth, abundant yield, and quality: and the "Tartarian" (black and white) for a great quantity of comparatively coarse quality.

Oats ground into a coarse meal form a considerable portion of the food of labourers and many men in the middle ranks of life in Scotland, Ireland, and the north of England. The meal is simply stirred into boiling water with a little salt, until it becomes of the consistency of a hasty-pudding; it is then called porridge; and when eaten with milk or treacle makes a wholesome and palatable food. It is sometimes mixed with the thin liquor of boiled meat, or the water in which cabbages or kale have been boiled, and acquires the denomination of beef-brose or kale-brose. When made into a dough with water, and baked on an iron plate in thin cakes, it makes a bread which is very palatable to those who are accustomed to it, and who often prefer it to wheaten bread. Its use was once almost universal in Scotland, which has in consequence been called the Land of Cakes. In Germany and Switzerland the coarsely bruised oatmeal is put into an oven till it becomes of a brown colour; it is then called haber-meel, and is used in broths and pottages, as the semolina, made from wheat, is used in France and Italy. The coarsely-broken grains, after the husk has been removed, form grits, which are extensively used to make gruel for children and invalids. The quality of oats as food is proved by experience, and has been amply illustrated by scientific research. Its grain contains 46 per cent. of starch, nearly 14 of nitrogen compounds, 6 of oil, 6 of sugar, nearly 4 of gum, besides 24 of husk, &c. And its straw contains 1·8 of nitrogen compounds, besides 66 of woody fibre and other organic matters. These figures were ascertained by Boussingault. The chaff of oats put into a canvas bag forms a good substitute for feather-beds for the poor, and is far more wholesome than feathers, from the ease with which it may be renewed at little or no cost.

In some countries the oats are given to horses in the straw, without threshing them; and where the quantity can be regulated, the practice is good. The horses masticate the corn better in the chaff, and the straw is wholesome; but where horses do hard work, they would be too long in eating a sufficient quantity, and it is better to give them oats threshed and cleaned, with clover hay cut into chaff. When hay is dear, it is often cheaper to increase the quantity of oats, and to give it with wheat-straw cut fine. In this way very little hay is required. The calculation is easily made when we consider that a pound of good oats gives as much nourishment to a horse as two pounds of the best clover, or sainfoin hay. A truss of hay of 56 pounds is therefore equal to 28 pounds of oats; or a bushel of the best oats will go as far as one truss and a half of hay; and if this quantity is worth *4s.*, which is at the rate of *4l. 16s.* per load of thirty-six trusses, the equivalent price of oats is *32s.* per quarter.

Farmers who have hay-ricks from which they often allow their men to take as much as they please for their horses, will carefully measure out the oats, which probably are much cheaper. Those who keep many horses should cut all the hay into chaff by a machiné, and mixing this with a proper proportion of oats, feed all their horses in mangers with a certain allowance of the mixture, a practice much more economical than that usually adopted. In France and Germany the practice of baking oats, as well as rye, into loaves for horse-food, is gaining ground, and is said to be attended by an evident saving of food.

OBELISK, a Greek word used to designate the well-known Egyptian monumental monolith. Obelisk (ὀβελίσκος) is a diminutive of *obelos* (ὀβελος), a sharp-pointed thing, a spit, or skewer; and was no doubt applied to the Egyptian obelisk on account of its shape and pointed end. Herodotus used the word ὀβελίσκος both for an obelisk (ii. 111), and a skewer or spit (ii. 41). The Italian name for an obelisk *aguglia*, and the French *aiguille*, are derived from the Latin *acus*, a needle or pin: a word applied also to the pin or bodkin used for fastening up the hair, and which instead of tapering to a point like a needle, sometimes, at least, had the end sloped off abruptly; as may be seen in Montfaucon, 'Ant.,' supp., plate iii.

The Egyptian obelisk is a tall, monolithic, four-sided shaft, which diminishes gradually from the base to near the top, when the sides are sloped off so as to form a pyramidion, or diminutive pyramid, which serves as the apex. In size, obelisks vary greatly; the shaft of the Lateran obelisk, the largest remaining, is 105 feet high, and was once more; while one at Florence, the smallest known, is under 6 feet in height. The larger Egyptian obelisks are almost invariably made of the red granite of Syene; the small ones of green basalt. Their sides are, with few exceptions, covered with hieroglyphics.

A great deal has been written respecting the origin and purpose of the obelisk, without any very definite result. It may safely be said, however, that the Egyptian obelisk was only a refinement on the stone of memorial which it was the general primitive custom to set up on special occasions or in holy places, of which that raised by Jacob at Bethel (Gen. xxviii. 18) is an instance that will occur to every one. Monoliths are in fact found among all the most ancient races. The Egyptians, a highly cultivated people, gave to theirs an artistic form. The peculiar tapering form and pointed termination were stated by Pliny to have been suggested by a tongue of flame; and the idea of fire, or the worship of the sun, seems to have been by some tradition generally associated among the ancients with the Egyptian obelisk. Be the original idea what it may, the Egyptians somehow succeeded in devising a form which in its way has never been equalled in grace of outline, or, where conjoined with magnitude, in imposing effect.

The Egyptians never placed their obelisks, as the moderns almost invariably do, alone, in a broad open space. They fixed them in pairs in front of the propylæa of a temple, and the hieroglyphics inscribed on their sides told the name and titles of the monarch who erected them, and the purpose of the building before which they stood. They were raised on low oblong bases or pedestals, which, however, were no part of the obelisk proper, but were formed of separate blocks of granite. The position of the obelisk will be understood by the cut of the very fine pair—the most perfect extant—which stood in front of the propylæa of the temple of Luxor: one of these has, since the drawing was made, been removed to Paris. The bases are hidden by the accumulated sand.

The shaft of an Egyptian obelisk is usually about eight, but sometimes ten times as high as the width of the base. The width at the top of the shaft, or base of the pyramidion, is one fourth less than the base of the shaft. The height of the pyramidion is from one to one and a half the width of its base. We have described the shaft as quadrilateral, but it is not square; two of the sides, the front and back, being generally somewhat wider than the other two. Neither are the sides perfectly flat. Under COLUMN and GRECIAN ARCHITECTURE it has been shown that, to atone for a certain optical appearance, the Greeks made the outline of their columns, and other lines which in appearance were right lines, to be in reality very slightly convex. In the same way, and doubtless for a similar reason, that is, to counteract a seeming concavity of surface observable in really flat-sided obelisks, the Egyptians made the sides of their obelisks slightly convex, or, as it is technically termed, to have an entasis on the plan. And it is noteworthy that Mr. John Bell, the distinguished sculptor, without being acquainted apparently with the Egyptian practice, was led to give precisely such an entasis to a monumental obelisk constructed by him, as the result of a series of tentative efforts made to overcome a seeming concavity of surface and horizontal plan observed by him in his model, and of which experiment he gave a full account in a paper read before the Institute of Architects, in May, 1858.

Obelisks in front of the Temple of Luxor.

At one time there must have been a large number of obelisks in Egypt, as they are traced all the way from Philæ to the Mediterranean. South of the first cataracts there are none of large size, owing, as is supposed, to the difficulty of conveying such large masses of granite up the river from the quarries of Syene. Since the Romans became masters of Egypt, the obelisks have been made a constant prey, and comparatively few are now left standing. Augustus was the first who removed any of these monoliths: one he caused to be placed in the Campus Martius, another in the Circus. The great obelisk of the Lateran was conveyed from Heliopolis to Alexandria by Constantine, and from thence removed by that emperor's son Constantius to Rome, where it was erected in the Circus Maximus. This obelisk is the largest now known, its shaft being 105 ft. (although it has been reduced, a portion at the lower part having been cut off in consequence of being fractured), and two of its sides, 9 ft. 8¼ in., the other two 9 ft.; the shaft weighs about 445 tons. That which was originally brought from Heliopolis, and placed in the Vatican Circus, and which now stands in the piazza of St. Peter's, is next in size to that of the Lateran, though supposed to have been somewhat abridged of its original dimensions. The entire height of the shaft itself is 83 ft.; it is 8 ft. 10 in. square at its base, and 5 ft. 11 in. at the other end. In all 48 obelisks were transported by the emperors to Rome; of these the five largest still remain, but only seven of the smaller ones have escaped destruction.

During the calamities that befel Rome under its barbarian invaders after the downfall of the empire, the obelisks were damaged and overthrown; but those not entirely destroyed have been gradually restored under various pontiffs. The first to attempt this was Sixtus V., and so much interest did the proposal to raise one of these shafts excite, that 500 different plans are said to have been sent in from various parts of Europe. The task was allotted to Dominico Fontana, who employed 600 men and 140 horses in raising it, and was so elated with his success, that he published full details of the process in a handsome folio volume. In all twelve obelisks have been erected in Rome, but the most entire ignorance or disregard has been shown of the principles which render these monoliths so graceful in their original state. Not only have they been placed on absurdly unsuitable pedestals—one, for instance, on the back of an elephant—but above the original termination (the simple and elegant pyramidion), has been fixed a cross, with other equally misplaced and often puerile ornaments. The following table contains a list of the Roman obelisks, arranged in the order of their modern restoration, with the dimensions of the shafts—but omitting the modern bases and crowning ornaments, and other particulars:—

I. The Vatican, in front of St. Peter's, where it was removed by Fontana from the Vatican Circus. On the side facing the church, and on the opposite side, we see the dedication to Augustus and Tiberius. Height 83 ft. 2 in. Without hieroglyphics, and still entire.

II. In front of the church of Santa Maria Maggiore, erected by Fontana. Height 48 ft. 5·1 in.; without hieroglyphics; broken in three or more places.

III. In front of the St. John Lateran church, erected by Fontana; Height 105 ft. 7 in. Hieroglyphics; broken in three pieces. This magnificent monolith was originally erected before the propylæa of the temple at Thebes by one of the kings of the 18th dynasty.

IV. Flaminio del Popolo, erected by Fontana. Height 78 ft. 6 in. Hieroglyphics; broken in three pieces. This was one of the two obelisks brought by Augustus from Heliopolis. These four obelisks were raised under pope Sixtus V. during the years 1586-89.

V. In the Piazza Navona; sometimes called the Pamphilian obelisk; erected by Innocent X., in 1651. Height 54 ft. 3 in. Has hieroglyphics, but not genuine ones, having been cut by order of Domitian. Fountain round the base.

VI. Minerveo della Minerva, erected by Bernini for Alexander VII., in 1667. This obelisk, with singular bad taste, is placed on the back of a horrible elephant, the work of Bernini. Height about 17 ft. Hieroglyphics.

VII. Mahuteo della Rotonda, raised by order of Clement XI. in 1711, in front of the Pantheon of Agrippa. Height 19 ft. 9 in. Hieroglyphics; probably the pendant of No. 6: fountain round the base.

VIII. Quirinale di Monte Cavallo, erected by Antinori for Pius VI., in 1786. Height 47 ft. 8 in. No hieroglyphics; appears broken in two or three places.

IX. Sallustiano della Trinità di Monte, erected by Antinori for Pius VI., in 1789. Height about 43 ft. 6 in. Hieroglyphics.

X. Campense di Monte Citorio, erected by Antinori for Pius VI., in 1792. Height 71 ft. 6 in. Hieroglyphics.

XI. Aureliano della Passeggiata, on the Monte Pincio, erected for Pius VII., in 1822. Height about 30 ft. Hieroglyphics. This is called by Zoëga the Barberini obelisk, of which he says, "Hic e Romanis obeliscis adhuc cognitis solus expectat sospitatorem."

XII. Private obelisk erected in 1817 on the Cœlian Hill, in the gardens of the Villa Mattei; hardly worth mentioning. It is a small fragment of a real obelisk mounted on a piece of modern granite.

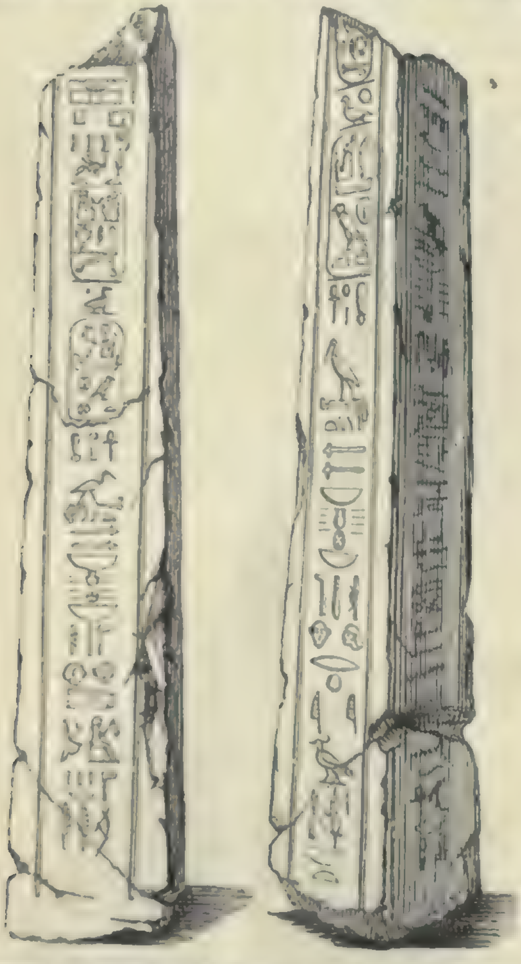
Cleopatra's Needle.

Of the two obelisks which Pliny mentions ('Hist. Nat.,' xxxvi. 9) as standing in front of a temple at Alexandria, only one is now standing. Like most of the monuments of Lower Egypt, it bears the name of the great

Rameses II. The annexed cut (col. 10) of this obelisk, popularly known as Cleopatra's needle, will serve to show the appearance of one of these monuments with its pedestal, as the cut of the Luxor obelisks illustrates their original position. The following are the dimensions of the Alexandrian obelisk:—Width of one base of shaft, 8 ft. 2 in.; width of same face of the obelisk at base of the pyramidion, 5 ft. 2 in.; width of other sides at base of shaft and base of pyramidion, 7 ft. 8·7 in., and 4 ft. 8·5 in., respectively; height of shaft to base of pyramidion, 60 ft. 7·6 in.; height of pyramidion, 6 ft. 6·8 in.; whole height of shaft, 67 ft. 2·4 in.; height of pedestal and plinths, 12 ft.; making the entire height of the obelisk and supports a little over 79 feet. The corresponding obelisk lies on the ground. This one was some time ago presented to the British government, but it was found to be so much damaged as not to be worth the cost of removal.

The largest Egyptian obelisk hitherto brought over to this country is that which was removed from the island of Philæ by Belzoni, at the cost of W. Bankes, Esq., and which is now erected at the family seat, Kingston Hall, near Weymouth, Dorsetshire. It is a monolith of red Egyptian granite, 22 ft. 1 in. in length, and its larger end, or base, 2 ft. 2 in. square, the other end being 1 ft. 5¾ in. It has a peculiar interest with Egyptologists, from a Greek inscription on its pedestal having enabled Champollion to determine the names of Cleopatra and Ptolemy, "to extend the alphabet, and to lay the foundation for the future decipherment and interpretation of the hieroglyphics." [HIEROGLYPHICS.]

The two small obelisks in the British Museum are also very interesting for their inscriptions, which are admirably executed. We give cuts of them as illustrations of the manner in which the obelisks are engraved: the animals are in the best style of Egyptian hieroglyphic art. They are of green basalt, and about eight feet in height, but as will be seen have been much broken.



The obelisk removed by the French from before the propylæa of the temple of Luxor is the smaller of the two shown *in situ* in the cut above (col. 9). It now stands in the centre of the Place de la Concorde, where it was fixed in 1836.

Before the cathedral of Catania, in Sicily, is a small obelisk, placed on the back of an elephant; and there is one at Arles (see the cut under the article ARLES, in GEOG. DIV.), but these are not really Egyptian, though frequently so described. In the At Meidan, in Constantinople, is an obelisk about 50 feet high, which is said to have been erected by the emperor Theodosius.

Much surprise has been expressed by writers that the Egyptians should have been able to quarry, remove, and raise such vast masses of granite. But the Egyptians were a people whose culture in the arts had reached a high point; they almost beyond any other people had experience in quarrying and working large masses of granite; they were familiar with the principles of mechanics, and with mechanical contrivances; and they had an almost unlimited command of human labour. An examination of Sir J. G. Wilkinson's 'Ancient Egypt and the Egyptians' would remove the difficulty, if we did not see by the examples afforded by a much less advanced people, the modern Indians, who by the simplest means first quarried and then removed and raised to its position the vast granite monolithic obelisk erected at Seringapatam in 1805, that with sufficient patient well-directed labour such tasks are accomplished with comparative ease. As to the removal of the obelisks—the proceedings of Belzoni, of the French in removing the Luxor obelisk, and especially those of Layard at Nineveh, are still more to the point. For descriptions of the methods adopted, it will be enough to refer to the authorities named below.

Assyrian Obelisks.—Among the remarkable discoveries made on the site or in the vicinity of the long-buried Nineveh, the finding of some monoliths resembling obelisks is not the least interesting. That now in the British Museum is the most important. It is a block of coarse black marble, 6 ft. 6 in. high, 2 ft. wide at the bottom, and 1 ft. 6 in. at top—where in the Egyptian obelisk the pyramidion would commence. The top in this instance, however, instead of sloping off to a point, as in the pyramidion of an Egyptian obelisk, diminishes by three steps, the termination being flat: Mr. Fergusson supposes this top to be a model of an Assyrian temple. As in the Egyptian obelisk, the sides of the shaft are narrower than the front and back. As a work of art, it is, both in design and execution, far inferior to the Egyptian obelisk; but as an historical monument it is of immense value. Each of the sides has five tires of bassi-rilievi, representing the king of Assyria receiving tribute from various conquered nations, consisting of prisoners, rare animals, vases, and other costly articles; and above, between, and below these are, in all, 210 lines of an inscription in cuneiform characters, which, as deciphered by Sir H. Rawlinson, was found to give an historical account of 31 years of the reign of Temenbar, ending about 885 B.C.

The very curious obelisk at Axum in Abyssinia, a granite monolith 60 feet high, but differing greatly in form from those of Egypt, is figured under AXUM, in the GEOG. DIV. There were once, it is said, more than 50 of these monoliths at Axum, of which four were equal in size to the one still standing. It stands on a base of three plinths; has rude sculptures, not hieroglyphics, on the sides; and is terminated with a round-topped patera. Its date is not ascertained; but it has been conjectured to be of Greek workmanship, and contemporaneous with a stone inscribed in rude Greek and, as Mr. Salt conjectures, Ethiopian characters, of about the year A.D. 300.

(Wilkinson, *Ancient Egyptians; Egyptian Antiquities*, in 'Lib. of Ent. Knowledge;' Hamilton, *Ægyptiaca;* Zoëga, *De usu et origine Obeliscorum;* Rossellini, *Monumenti dell' Egitto;* and the great work of the French government on Egypt; Layard, *Nineveh;* Bonomi, *Nineveh and its Palaces.*)

OBESITY is an excessive accumulation of fat in various parts of the body. It is not possible to define the boundary beyond which the fat in the body can be called excessive, for persons possessing it in the most varied degrees enjoy equally good health, and the same person may at different times possess more or less without any injury to his comfort. According to the calculations of Dr. Lankester ('Guide to the Food Collection,' South Kensington Museum) a human body weighing 154 pounds contains 12 pounds of fat. This quantity may be exceeded to a very large extent without producing obesity.

An excessive development of the adipose tissue may take place at any period of life. It is not uncommon in children; is far more rare in youth and in the early periods of manhood; and is most common after the age of 40, at which time an increase in the quantity of fat is observed in perhaps the majority of persons.

The chief accumulations of fat take place beneath the muscles, in the omentum and mesentery, about the heart, on the chest, and under the chin. In all these parts a certain quantity of fat naturally exists, and here therefore its amount is merely increased; but in cases of excessive obesity, it accumulates in situations where before there was none, as among the minute fibres of the muscles, even of the heart, and in various other tissues.

The accumulation of fat in the body produces a variety of effects. It is generally accompanied with an indisposition to exertion, and this at last so far prevents the growth of muscular tissue that stout persons become exceedingly feeble. This is also true of horses and oxen, which lose their capacity to labour as they become fat. Another evil attendant upon fatness is that the heart being taxed in proportion to the increased size of the body, becomes enfeebled, and local congestions and irregularities of the circulation are frequently the result. A proper expansion of the chest, and a free action of the abdominal muscles are also prevented, which lead to shortness of breath on slight exertion. Although persons may be stout and live to a good old age, yet their path is beset with danger, and their chances of life are not so great as amongst persons with a normal quantity of adipose tissue.

The causes of obesity are both natural and acquired. It is well known that among domesticated animals some have a greater tendency to accumulate fat than others, and such breeds are kept up for the purpose. In the same way there are human beings who exhibit the same tendency, and in the case of certain individuals the most persevering measures fail to reduce their weight. On what this tendency depends it is difficult to say exactly, but there is reason to believe that it depends upon the food in the early stages of digestion being converted into fat, which getting into, the blood is deposited in the adipose tissue by a kind of excretory process. In such individuals the starch and sugar of the food appear to be more readily convertible into fat than in others. But whilst this tendency may naturally exist, it can be greatly increased by diet. There can be no doubt that the class of foods called carbonaceous,—starch, sugar, and fat—when taken in larger quantities than are required to maintain the heat of the body, are employed in developing the adipose tissue. Experiments on the feeding of animals have shown that in proportion as these substances are employed in the food do they become fat. Alcoholic beverages, when not taken to such an excess as to produce more disastrous results, have a tendency to produce fatness. They act in the first place by stimulating the digestive process, and in the next by preventing that action of the oxygen of the air on the blood and tissues by which the carbonaceous foods are oxygenated and carried off in the form of carbonic acid. Sedentary and indolent habits also have a tendency to produce fatness. As it is by active exertion that the oxygen of the atmosphere is introduced to the tissues of the body, and they are changed and carried away, so if this process be prevented by indolence, the tissues go on developing, and this is frequently the case with the adipose tissue. Heat has also a tendency to develope obesity. Living in warm rooms, or in a warm climate, other things being equal, has a tendency to produce fatness.

Whilst obesity is exposed to dangers of its own, a precipitate anxiety to keep it down or prevent it is most earnestly to be deprecated. The practice of taking vinegar to prevent obesity is attended with great danger, as it acts by destroying the digestive power of the stomach. Persons also frequently put themselves on a short diet, and without not only fat-forming matters but also flesh-forming matters in their food. In this way the heart soon breaks down for want of nourishment, and death occurs in a variety of ways from want of power in the central organ of the circulation. The entering also at once upon a system of hard exercise and short sleep is frequently attended with the death of the patient. The great object of treatment should be the gradual reduction of the fat, whilst the muscular power, especially of the heart, should be maintained. One of the most important things to be attended to is the nature of the diet. The amylaceous, saccharine, oleaginous, and alcoholic parts of the diet should be diminished. No butter at breakfast, no bread at dinner, and one glass of wine a day is a good receipt for a healthy fat man who has been in the habit of living indiscriminately. Hard biscuits may also be advantageously substituted for bread. Regular exercise should be taken, never excessive. Sawing, digging, walking and mountaineering according to the weight and strength of the patient are all good. Generally the obese are infirm of will, and this bodily state is perhaps connected with their mental condition, and of all patients they seem least able to make up their minds to the necessary discipline for their cure. If the persuasion implied in the sentence of "six months at the treadmill" could in any manner be applied in their case, it would undoubtedly be the most effectual remedy.

OBJECT-GLASS. The lens or system of lenses nearest the object in a telescope or microscope. As explained under Eye-piece, its business is to form a correct image of the object within the tube; hence it should be free from spherical aberration, and should be achromatic. For the method of rendering it so we must refer to Microscope, and for a due understanding of the defects, to Aberration in optics. [Achromatic; Lens; Light.]

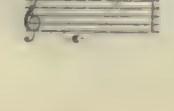
OBLATE, a term applied to a spheroid which is made by the revolution of an ellipse about the smaller of the two axes.

OBLIQUE. This term is used as opposed to direct or right, and signifies whatever is not direct or right. The word seldom appears, except as expressing that an angle is not a right angle, all other uses of it being almost obsolete.

OBLIQUITY, a term used in astronomy to express the angle made by the ecliptic with the equator. The greatest latitude at which the sun ever appears vertical is the obliquity of the ecliptic. [Sun; Precession and Nutation.]

OBLONG, a word in common use, expressing the same meaning as, and in our opinion preferable to, the mathematical term rectangular, or having the figure of a rectangle.

OBOE (*Ital.*), a musical instrument of the pneumatic kind, blown through a reed: it is a tube of boxwood, 22 inches in length, slender in the upper part, but spreads out conically at the lower end, and consists of three joints, or pieces, besides the reed. Its compass is two octaves and a fifth, from c below the treble clef, to g, the fourth added line above it:—



Modern improvements have augmented the resources of the oboe by means of eleven keys, but only skilful performers can safely be trusted to produce the two or three highest notes; and till very recently, e, or even c, above the staff, was considered the utmost practicable extent of the instrument. Oboes are now frequently made to go down to b♭, in which case they exceed the usual length, and have an additional key.

The oboe has for centuries past been in use, and may be traced back to the reign of Edward III., in whose band oboes, under the denomination of *Wayghtes*, were employed. Indeed our itinerant parish-musicians, the official precursors of what was once a merry season, retain the appellation of *Waits*, though they have long abandoned the instruments which conferred on them their title.

Up to nearly the close of the last century, this instrument was only known, in most parts of Europe, by its French name, *Hautbois*, a word which in England has always been pronounced *Hoboy*; and this pronunciation has been transferred to the Italian term, though the word oboe is now invariably adopted in writing.

OBOLUS (ὀβολός), was a Greek coin, both silver and brass. At Athens it was of silver, the sixth part of a drachma, and worth somewhat more than five farthings sterling. The Æginetan obolus is stated to have been heavier than the Athenian. It is generally supposed that *óbolus* and *óbelos* (ὀβολός and ὀβελός) were originally the same word differently pronounced, and that the coin *obolus* was first of iron or copper, in form like a spit, which the word also means, or a bar; that a handful made a *drachme* (δραχμή); and that the form was afterwards changed from an oblong to a round shape, but that though struck round, like other money, it continued to retain the ancient name. Others say that the obolus was originally so called from being stamped with the figure of a skewer or spit, or other sharp-pointed instrument.

The Greeks had an hemi-obólion (ἡμιωβόλιον), or semiobolus, and a *trióbolon* (τριώβολον), or silver coin of three oboli, which was the common pay of the Dicastæ; the pay originally having been two oboli. Two *oboli* were placed in the mouth of a dead person, in order to enable him to pay for his passage over Styx. According to Lucian, Charon's demand was only one obolus. (Aristoph., 'Frogs,' 141; Lucian, 'Catapl.,' i., p. 643.)

According to Suidas (ὀβολός), the Athenian *obolus* contained six *chalci* (χαλκοί), and the *chalcus* contained seven *lepta* (λεπτά). Other authorities say that the *obolus* contained eight *chalci*. [Numismatics.]

OBSERVANTS, or OBSERVANTINS. [Franciscans.]

OBSERVATION AND EXPERIMENT. The first of these terms includes a portion of the second, inasmuch as every experiment is made with a view of observing the result. But experiment signifies more than observation, implying a disposition of means of observation which it is in the power of the experimenter to make for himself, and which he actually did make for himself. If, for example, a person who observed the attraction of the magnet for the first time, dubious of the residence of the attracting power, were to move the magnet to another place, that he might see whether the attracted body would still move towards it, he would make an experiment. But if his magnet were the sun and the attracted body the earth, he could only wait the proper times for observing the motion of the latter with respect to the former, in order to establish the attraction. Thus astronomy, geology, meteorology, natural history, &c., are sciences of observation (that is, of nothing but observation); while mechanics, optics, electricity, &c., are sciences of experiment. In one sense geology and meteorology are partly sciences of experiment, since portions of the material subject-matters of these sciences may be submitted to preconcerted tests. It would, however, be more proper to consider mineralogy and aero-mechanics as the experimental sciences connected with these, than to class them as mixed sciences.

To give an account of experiment would require us to explain the methods of every science which proceeds upon it: to give a detailed account of observation, we should need the description of all the means or instruments by which our senses are assisted in the examination of phenomena. We shall here confine ourselves to a short sketch of the errors which render observations discordant, and which make a final process of combination necessary in every case in which we cannot command results which agree with each other so well that the difference between them is imperceptible to the senses.

Everything which is called observation is of two kinds; in the first a simple individual fact is noted, in the second a magnitude is measured. The results of the first species are the proper subjects of inductive reasoning only; the results of the second, of inductive and mathematical reasoning, either or both. Individually, the first kind of observations are not necessarily subject to error; thus a zoologist observing the structure of a new animal might in every instance correctly note the resemblances which exist between it and other animals, and might refer it to its proper class in a manner which centuries of succeeding observation would not induce naturalists to disturb. Collectively, however, wrong inferences might be drawn from facts; thus results of classification which are true of all animals known up to one moment, and are therefore inferred to be always true, may be disturbed in the next moment by the discovery of a new specimen.

Observations of the mathematical character are of necessity erroneous from the imperfections of our senses. When a new insect is observed, it is soon seen, for instance, whether it has or has not wings, and the question once settled is finally settled. But when, say the specific gravity of a gaseous substance, at a given pressure and temperature, is *measured*, it is impossible to consider the question as settled at any time. Say that, under given circumstances, the specific gravity is asserted to be ·934 of that of air similarly circumstanced; this is only an admission, at most, of its being somewhere between ·9335 and ·9345. And that which we call an exact measurement of a length may for one purpose mean within a hundredth of an inch, for another within a thousandth, and so on; but no person dreams of having attained absolute truth. This being well known, and every process used in observation being subject to error, it is the business of the observer to repeat observations many times, and to extract a result as near to the truth as may be, from the mass of discordant materials which the repetition will furnish.

The necessary errors of observation arise from the imperfection of our perceptions and of the instruments which we use, and also from hasty or otherwise incorrect conclusions. The subject requires the separation of these errors into three classes, which may be mixed up with one another in results, and may be mistaken for one another. We may call them *fixed*, *personal*, and *casual*.

By a *fixed* error we mean one which is inherent in the instrument or method employed, so that it must exist, and, all other things remaining the same, must have a given magnitude. Thus, if the axis of an equatorial (supposing such an instrument to be employed for absolute measurements) do not absolutely coincide with that of the heavens, the right ascension and declination of a given star, measured when at a given distance from the meridian, must have a given error. It might be precisely the same in numerical effect, and would certainly produce an error of the same class if the observer used a wrong formula in the reduction of his observations. Thus, it would be perfectly possible to give to one observer an incorrect instrument and a correct formula, and to another a correct instrument and an incorrect formula, in such manner that their final results should coincide.

Errors of this kind cannot be detected by multiplying similar observations, since there can be no tendency to destroy error in the mere repetition of it. There are many modes of detecting fixed errors, and of allowing for them; but the only mode of avoiding them is by taking advantage of the construction of the instrument to use it for the same purpose under different circumstances, in such manner that measurements which are too large in one set of results must be as much too small in the other. If the same number of observations be contained in each set, this, as we shall presently see, is really a reduction of the fixed error to the class of casual ones; or rather, a destruction of the fixed error by the same process which gives the highest probability of destroying the casual errors.

All instruments must be more or less erroneous in every particular. In the science of observation, as now understood, and in any matter in which the utmost attainable exactness is requisite, the assumption of perfection in an instrument, in any point whatsoever, is looked upon as nothing but the expression of the observer's unwillingness to take trouble. For even if ninety-nine successive days' trials have shown that any particular error does not exist to any sensible amount, it is not conclusive against the observations of the hundredth day being affected by some new circumstance, necessary or accidental, in which the instrument has been placed in the intermediate time.

By a *personal* error is meant one of the same character as a fixed error, but arising from the temperament or habits of the observer, and not from the instrument. Thus if A should, in noting the time of a phenomenon by the clock, have a tendency to accelerate the moment of its happening, and B a similar tendency to retard it, the results of the two would differ by the sum of their personal errors. It has been discovered that two individuals, observing the same phenomenon with the same species of instruments may differ sensibly (though but little) from each other; and this not once or twice, but nearly always, and in such a manner as to make the average of a set of observations of one observer differ from that of the other. For anything we can know to the contrary, this species of error may exist in every observer; and its absolute quantity must be unknown until we can compare the observations of men subject to it with those of some other beings who are not. If indeed the personal error be purely casual, so that where one person measures too much, another measures as much too little, the average of the results of a large number of observers would give the truth or very near it. But should it be the case, which is not impossible, that all men are subject to an error of the same kind, some more and some less, namely, that all measure more or less too much, or else, that all measure more or less too little, the average above mentioned would give, not the truth, but the truth affected by the average error of all the observers. Nor would the results obtained ever enable us to distinguish whether personal errors have a fixed average or not; for suppose the fact observed to be that A, one time with another, measures more than B; this *may* mean either of several things:—either A measures truly, and B too little; or B measures truly, and A too much; or B measures too little, and A too much; or both measure too little, but B more than A; or both measure too much, but A more than B. Now, if A and B were to observe together for a century, the mere comparison of their observations, though it would settle their average amount of difference, would never enable us to give the least guess which of the preceding cases is the true one. If indeed we could convert the observer, as we have previously mentioned might generally be done with the instrument, into another observer with an error of the opposite kind, a true result, or one sensibly true, might be obtained. Suppose, for example, it is the observer's habit, in noting the transit of a star over a fixed wire in the field of a telescope, to take the transit too soon when the star comes in on the right side, and too late when on the left: consequently, by making a number of observations with an inverting telescope, and an equal number with one which does not invert, the average of both sets would be as likely to give a true result as if neither error had existed. [EQUATION, PERSONAL.]

All the errors which precede, though called errors because they give a result which is not the one intended to be obtained, yet are in fact the consequences of an actually existing state of things, and their laws can be determined by using the right means, or at least must be supposed to arise from natural causes measurable by experiment in the same manner as other consequences of existing relations. They are then really measures of phenomena, called errors simply because the effects of their causes are to be removed from the results. It is even possible that they might be made intentionally in a given form, with a view to prevent their occurrence in a more objectionable form. Thus, suppose an observer finds himself, in correcting discordant observations, apt to confound additions and subtractions, using one for the other: he will set his instrument intentionally wrong to an amount which casual discordances never reach, taking care, of course, to preserve means of correcting the intentional error with the rest; so that the requisite correction shall always be of one kind, additive or subtractive. Nevertheless this arrangement, as it should be called, would go by the name of an error, simply as being to have its effect afterwards destroyed.

By *casual* errors, the only ones to which the name of errors can properly be given, are meant those which are absolutely inexplicable, or of which the cause and tendency are equally unknown. They must be considered as equally likely to be positive or negative; so that in the long run the results which they give too great will be compensated by those which are too small. If this be not the case, that is, if there be a greater tendency to too much than to too little, there must be a reason for this phenomenon, and a law of action, which must be sought for and detected. Let us suppose this done, so that any result of a single observation, corrected for all discoverable sources of error, is in itself as likely to be too small as too great.

If all the observations be equally good, the MEAN, or average, is more likely to be true than anything else. This is even true with reference to fixed or personal errors which may remain, but which are totally unsuspected; for there is an even chance of such errors acting in either way. In the article just cited is shown the way of finding, from the observations themselves, the probable error, as it is called, or that which there is an even chance of not exceeding; with references to further sources of information. This article [MEAN], together with the general considerations in PROBABILITIES, THEORY OF, and WEIGHT OF OBSERVATIONS, will contain all we shall find it necessary to say on the subject.

It might be supposed that the greater the number of observations, the less, in the same proportion, the probable error of the average; but this is not true, since the probable error diminishes as the *square root* of the number of observations increases. Thus, suppose it to be well settled that twenty observations of a given observer will have an average of which it is an even chance that it does not err by (say) a unit: then the same observer must make *four* times as many observations to get an average with an even chance of not more than *half* a unit of error; *nine* times for one-*third* of a unit, and so on.

Those who neglect sound principles of observation are apt to overrate the effect of multiplying observations; which, though considerable, does not, as we see in the above rule, keep pace with the number of observations.

OBSERVATORIES, ASTRONOMICAL. We possess only an imperfect knowledge respecting the institutions established in ancient times for the observation of the heavenly bodies. The observatory of Alexandria is alone famous in the history of Greek astronomy. It was there that the observations were first made, upon which astronomy as a science, in the true sense of the term, was finally founded. With the revival of science in modern Europe, the establishment of observatories was soon felt to be indispensable to the progress of astronomy. The observatory of Tycho Brahé, erected in the island of Huena towards the close of the 16th century, under the auspices of Frederick III., king of Denmark, is memorable in the history of astronomy for having supplied the facts which enabled Kepler to destroy the epicyclical mechanism of the planetary movements, and to substitute in its stead the true theory of elliptical motion. About the same time William, Landgrave of Hesse Cassel, did good service to astronomy by the erection of an observatory, and the prosecution of a series of observations of the heavenly bodies. The lustre shed upon his country by the labours of Tycho Brahé doubtless acted as a powerful incentive in stimulating the Danish sovereigns to patronise astronomy. We accordingly find that the earliest national observatory of modern Europe was established in Denmark. The observatory of Copenhagen was commenced in 1637, but it was not completed until the year 1656. The first astronomer who was appointed to the direction of its labours was Longomontanus, the celebrated pupil of Tycho Brahé.

In the latter part of the 17th century a great impulse was given to practical astronomy by the invention of the micrometer, and the application of telescopic sights to the observation of the heavenly bodies. During this period the observatories of Greenwich and Paris were erected. We proceed to give a brief sketch of the history of the former of these institutions, although as regards priority of establishment the Paris Observatory has the advantage by a few years.

The Royal Observatory of Greenwich was established in the year 1675. The foundation stone of the building was laid on the 10th of August, and it was finished in less than twelvemonths afterwards. Flamsteed was appointed Astronomer Royal, with a salary of 100*l.* a-year. In the warrant of Charles II. for the payment of his salary, he is styled "our Astronomical Observator;" and he is directed "forthwith to apply himself with the most exact care and diligence to the rectifying the tables of the motions of the heavens, and the places of the fixed stars, so as to find out the so much desired longitude of places for the perfecting the art of navigation." Flamsteed took up his residence at the Observatory on the 10th of July, 1676, and shortly afterwards commenced his duties as an observer. In this capacity he continued to officiate till his death, which occurred towards the close of the year 1719. His observations are collected in an important work, entitled 'Historia Cœlestis Britannica,' published in three volumes folio; the third volume contains a catalogue of 2935 stars, reduced to the beginning of the year 1689.

The second director of the Greenwich Observatory was the celebrated Edmund Halley. His earliest observation is dated October 1, 1721. His labours were chiefly confined to observations of the moon. The results of these observations are inserted at the end of his planetary tables, published in 1749. No other observations made by this astronomer during his directorship of the Greenwich Observatory have been published. The original records of his labours are deposited in the Royal Observatory in four small quarto volumes. Upon the recommendation of Francis Baily, a copy of these observations was taken by order of the Lords Commissioners of the Admiralty, and presented to the Royal Astronomical Society in the year 1832. Halley died on the 14th of January, 1742.

Halley was succeeded in the office of Astronomer Royal by Bradley, who had already rendered his name for ever illustrious by his discovery of the aberration of light. In 1749, the Observatory having been furnished with a brass quadrant of eight feet radius, constructed by the celebrated artist, Bird, Bradley commenced a series of observations with the new instrument, which he continued to prosecute till shortly before his death in the year 1762. The results of his labours were subsequently published at the expense of the University of Oxford in two folio volumes, the first volume in 1798, under the superintendence of Dr. Hornsby, and the second in 1805, under the editorship of Dr. Robertson.

Bradley's observations of the stars have been reduced and discussed by the celebrated Bessel in a work published at Königsberg, in one volume folio, in the year 1818, entitled, 'Fundamenta Astronomiæ pro anno 1755, deducta ex observationibus viri incomparabilis James Bradley, in specula Astronomica Grenovicensi per annos 1750-62 institutis.'

Bradley is universally regarded as one of the greatest observers of ancient or modern times. The year 1750, when he commenced his labours with Bird's quadrant, may be considered as the epoch whence date observations comparable in precision with those of the present day. Henceforward the observations made at Greenwich have been employed almost exclusively in all the more important investigations of astronomy. Nor must we omit to state, that it was during his career as Astronomer Royal that Bradley made the series of observations, which resulted in his great discovery of the nutation of the earth's axis.

The successor of Bradley was Dr. Bliss, Savilian Professor of Geometry in the University of Oxford, who died in 1765. The next Astronomer Royal was the famous Dr. Maskelyne. His observations embraced the determination of the positions of the sun, moon, and planets, and a select number of stars; and he continued to adhere to this plan throughout the whole period of his career. Maskelyne first introduced the practice of observing the transit of a star at five vertical wires of the telescope. He was also the first who noted the transit of a star in terms of tenths of a second. His death occurred in the year 1811. The results of his observations have been published in four folio volumes.

Maskelyne was succeeded by Pond, who had already distinguished himself as a practical astronomer, having in the year 1806 communicated a paper to the Royal Society, in which he demonstrated that the brass quadrant of the Royal Observatory had undergone a change of form since its erection in Bradley's time. It was doubtless this circumstance which induced Maskelyne to solicit from the Government the construction of a mural circle of six feet diameter by Troughton, a request which was complied with; but the instrument was not quite finished at the time of his death. Soon after his accession to the office of Astronomer Royal, Pond commenced a series of observations with the mural circle, in the prosecution of which he evinced a high degree of talent. He first introduced the practice of observing a star by direct and reflected vision. The objects of his labours, besides the sun, moon, and planets, included also a considerable number of the stars. The observations in right ascension at the Royal Observatory, subsequently to the year 1816, were made with a new transit instrument of ten feet focal length, constructed by Troughton. In 1833, Pond published a catalogue of 1112 stars, which proved of great value to the practical astronomer. He retired from office in 1835, and died in the following year.

Pond was succeeded by Mr. Airy, who still continues to hold the office of Astronomer Royal. He had been previously Plumian Professor of Astronomy in the University of Cambridge, and had also been Director of the Cambridge Observatory since the year 1828. While engaged in the latter capacity he set the example of reducing all his observations as soon as they were made, a practice which has since been adopted at all public observatories. This eminent astronomer has signalised the period of his career at the Royal Observatory by numerous operations of great importance. Upon his recommendation, the Lords Commissioners of the Admiralty defrayed the expenses of reducing all the observations of the moon and planets made at Greenwich from 1750 to 1830. The results for the planets were published in 1846, in one quarto volume; those relating to the moon were given to the public in 1848, in two large quarto volumes. Several important catalogues of stars have emanated from the Royal Observatory during Mr. Airy's directorship. [ASTRONOMY.] In the instruments of the Observatory great improvements have also been effected. In 1847 an altitude and azimuth circle of a peculiar construction (termed an altazimuth) was erected, for the special purpose of making observations of the moon out of the meridian. In 1851 a powerful transit circle was erected, and henceforward all observations, both of right ascension and polar distance, were made with the same instrument. In 1852, an instrument termed the reflex zenith tube was erected, the object of which is to make observations near the zenith, mainly for the purpose of determining the value of aberration. In 1853 the American method of recording transits of stars by electro-magnetism was introduced at Greenwich. In 1859, observations were commenced with a magnificent equatorially mounted refractor of 12 inches aperture. It may be remarked, finally, in connection with this brief sketch of the Royal Observatory, that a great number of chronometers for the Admiralty are being constantly rated at the same establishment.

The other public observatories of the British Isles are those of Oxford, Cambridge, Portsmouth, Durham, Liverpool, Edinburgh, Glasgow, Dublin, and Armagh. Of private observatories may be mentioned the following:—The observatory of Mr. Bishop, Regent's Park; the observatory of Mr. Warren De La Rue, Cranford, Middlesex; the observatory of Mr. Carrington, Redhill; the observatory of Mr. Whitbread, at Cardington, in Bedfordshire; the observatory of Dr. Lee, at Hartwell; the observatory of Lord Wrottesley, at Wrottesley Hall; the observatory of Mr. Lassell, at Bradstones, near Liverpool; and the observatory of the Earl of Rosse, at Birr Castle, Ireland.

The Royal Observatory of Paris was commenced in the year 1667, but was not completed until 1671. Its early history was illustrated by the labours of Dominique Cassini and Picard. M. Le Verrier, one of the independent discoverers of the planet Neptune, is the present director of that establishment. The only other public observatories of France are those of Marseille and Toulouse.

Perhaps no country in Europe is so richly endowed with public observatories as Germany. In the north of Germany we find the observatories of Berlin, Königsberg, Breslau, Bonn, Göttingen, Gotha, and Hamburg; in the south there are the observatories of Vienna and Munich. The observatory of Königsberg is celebrated for having been the scene of the labours of the illustrious Bessel.

In Italy there are numerous public observatories, of which the most famous is the observatory of the Collegio Romano, Rome, directed by the distinguished astronomer, Professor Secchi.

In Russia great efforts have been made during the present century to promote the cultivation of astronomy. The Imperial Observatory of Pulkowa, directed by the celebrated astronomer M. Struve, is perhaps the most magnificent institution that has ever been established for the advancement of practical astronony. There is also in Russia the observatory of Dorpat, directed by Professor Mädler; and the observatory of Moscow, of which Professor Schweizer is director.

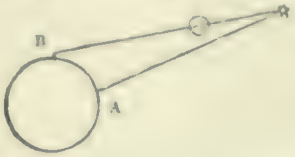
Observatories have been established throughout the other countries of Europe. A list of these establishments is given in the article ASTRONOMY

In the United States of America great progress has been made during the last quarter of a century, in the cultivation of practical astronomy, and a number of flourishing observatories are now in active operation. Of these the most celebrated are the National Observatory, Washington, and the Observatory of Harvard College, Cambridge, Massachusetts.

OBTUSE, opposed to acute, is applied to an angle which is greater than one right angle and less than two.

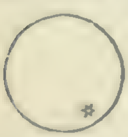
OCCULTATION. This word, which might serve to design any eclipse of one heavenly body by another, and even the effect of cloud or fog, is particularly applied to the eclipse of a fixed star by the moon. It has been seen [MOON] that the spiral course of the moon's real orbit must bring her at some time or other in the course of a revolution of the nodes (18¾ years) at or near to every star situated within about 5° of the ecliptic either way. There are consequently continual occultations of stars by the moon; such of which as can be made useful in finding the longitude are given yearly in the 'Nautical Almanac.'

If the moon were (like the star) so distant that two spectators at nearly opposite points of the earth would not be sensibly removed from each other in space when their distance from each other was compared with their common distance from the moon, then all observers, wheresoever situated, would see the moon begin to hide a star at the same instant. They would all then be able to note by their different clocks the absolute instant of the same phenomenon; and [LONGITUDE] their differences of clock-time at this absolute instant would give their differences of longitude. But the proximity of the moon makes it possible that one observer (at A) may see no occultation at the time when such a phenomenon has occurred to another (at B); and makes it



certain that two observers cannot see the beginning of an occultation at the same instant of absolute time. Both therefore must deduce from their own observed times of commencement, and from their knowledge of the moon's place and motions, the times, at their several places, at which a spectator situated at the earth's centre would see the star touch the moon's limb; and this being done, they are in the same position as if the moon had been too distant to require such a process. If, in this work, we had given the details of astronomical calculations, we should not have separated that required in reducing an occultation to the earth's centre from the similar case which occurs in an eclipse of the sun or a transit of Venus: the principles employed in all are identical, though the first process is rendered more simple than the second or third, by the very great distance of the star, which may be considered as marking the same point of the heavens at all places. For the value of observed occultations in finding the longitude, see the article LONGITUDE.

Here we might close this article, if it were not for a singular circumstance which sometimes occurs; and which cannot be traced either to the character of the telescope employed, of the observer, of the weather during the observation, or of the particular star under occultation. When the moon approaches the star, instead of an instant of contact, followed by disappearance of the star, the latter for a few seconds is frequently thrown upon the moon, as if it were the nearer body, and were going to cross the moon's surface, as Venus does that of the sun during a transit. While this is taking place, which sometimes lasts until the star has fairly left the moon's limb or border, the star preserves its light, though it frequently undergoes a change of colour. Aldebaran, whose natural colour is inclining to red, has been seen to present this phenomenon much more frequently than any other star: but θ Tauri, θ^1 and θ^2 Pleiadum, Spica Virginis, Regulus, γ Libræ, 132 Tauri, α^1 Cancri, 49 Libræ, λ Aquarii, 249 Aquarii, 187 Sagittarii, γ Tauri, ρ Leonis, ρ Geminorum, δ Cancri, δ Piscium, &c., have been seen more or less to come upon the moon's limb. See a detailed list of quotations from the different observers in a paper by Mr. South, On the Occultation of δ Piscium by the Moon,' in the third volume of the 'Memoirs of the Astronomical Society.' It is to be noted that many of these appearances did not exhibit the whole of the phenomenon, but made the star hang for some seconds upon the moon's limb, instead of immediately disappearing.



The occultations of Aldebaran approaching again in the years 1829 and 1830, the Society just mentioned invited the particular attention of astronomers to them. The consequence was, a large number of communications from different parts of Europe, which are printed in the fourth volume of their Memoirs. Nothing can be more different than the results: some, now saw the phenomenon for the first time; others, who had seen it before, did not see it; some, who had never seen it before, continued unable to do so. Of six observers at the Royal Observatory, five distinctly saw the projection on the moon's limb, and one saw it hang on the edge of the moon five or six seconds before it disappeared. Of three at the Observatory of Paris, two distinctly saw the projection, and one saw the star disappear instantaneously, leaving a shade ("ombre") on the part of the moon at which it disappeared. The majority saw the star either projected or hanging on the moon's edge. It is to be noted that this phenomenon has been seen at the dark edge of the moon as well as at the enlightened. Its cause is matter of much diversity of opinion.

The most recent explanation is due to Mr. Airy, who in the year 1859 communicated a paper on the subject to the Royal Astronomical Society, which is to be found in the twenty-eighth volume of the 'Memoirs' published by that body. Mr. Airy remarks, "that on the principles of the undulatory theory of light, the image in a telescope of any luminous point, whether a star or a portion of the moon's illuminated surface, is not a point." This is exemplified in the case of the bright rings which surround the image of a star as seen in a good telescope. It is plain also, for the same reason, that the aggregate of light produced by the aggregate of all the luminous points of the moon's disc, is not a luminous image bounded by a sharp outline, at what we consider the geometrical outline of the image, but that the geometrical outline is fringed by a band of illumination, produced by the interlacing and superposition of all the systems of rings. Hence it follows that when, with a very fine telescope we see the moon's limb very sharply defined, and apparently surrounded by immediate darkness, we do in reality see it erroneously. Mr. Airy conceives that during ordinary observations of the moon, the conviction that the outline of light ought to correspond to a given curve, may affect the visual organs so as to incapacitate them from perceiving the fainter light beyond that curve; but that in the excitement and intentness of observing an occultation, the state of the sensational organisation is probably much changed, and as the presumed time of the phenomenon comes nearer and nearer, the eye probably becomes more and more sensible to the faint diffused light, and the visible boundary of light extends further and further into the darkness. In numerous instances when the boundary of the moon's light has swelled till it touches the star, it swells no further, and the star hangs on the moon's limb. According to Mr. Airy, it seems perfectly conceivable, that the mental contemplation of the relation of the positions of the moon and star which is implied in the phenomenon that is to be observed, may frequently so far act on the sensibilities, that when that relation (namely, contact) is once gained, the mental effort does not make the sense more acute than is necessary, and may even somewhat relax as the denser light of the moon reaches the star. This explanation, it will be seen, refers the phenomenon to the principle of the irradiation of light.

OCCUPANCY. This term in English law signifies the taking possession by any person of any thing which has no owner (Bracton, fol. 8, *b*), and the general doctrine, as stated in Bracton, is derived from the *Jus Gentium* of the Roman lawyers, as explained in the 'Digest' (lib. 41, tit. 1, s. 1, 3, 5, &c.). That use of the term which will be here explained has reference to the occupation of land.

An estate *pur auter vie*, or for the life of another person or persons, had formerly some peculiar qualities incident to it. If a man had an estate in land for his own life, such estate was of course determined by his death. But if he had an estate in land for the life of another person, and he or his assignee died before such person, the estate was not determined, and yet there was nobody to take it, inasmuch as it could not go to the heir, nor, being a freehold interest, to the executor or administrator. Such an estate belonged to the first person who could take possession of it, and he was entitled to hold it as general occupant till the expiration of the life for which it was originally granted. But if the original grant were to A and his heirs, for the life of B, and A died during the life of B, the heir of A took the estate as special occupant—that is, as a person designated in the original grant. Sometimes the heir was said to take the estate as a descendible freehold, though the estate is admitted not to be an estate of inheritance, and therefore not subject to courtesy or dower,—it not being perceived that to say an estate is not an estate of inheritance and yet is descendible, is a contradiction, for descent implies an heir who takes as heir. Still it appears from Bracton (fol. 26 *b*, 62 *b*), that if lands were given to a man and his heirs for the life of another person, the heir could recover the land by an assise of *mort d'ancestor*, because the ancestor died seised as of fee, and a man could claim by an assise of *mort d'ancestor* any land of which his ancestor was seised as of a fee (*ut de feodo*); and hence it has been concluded that the heir took not as special occupant, but that he took a descendible freehold. This subject of occupancy, general and special, is discussed at great length and with considerable acuteness by Vaughan, Justice. (Vaughan, Holden *v.* Smallbrooke.)

In the case of copyhold, when there was no special occupant, the lord took the estate; for the lord, having the freehold, was also considered to have the possession; and therefore "vacancy," the necessary condition to any other person's title by occupation, was wanting. In the case of a rent or other incorporeal hereditament, when there was no special occupant, inasmuch as there could be no entry, there could of course be no possession or title by general occupancy.

It is stated by Bracton, that if land was given to a man for the life of another without any mention of his heirs, the land on the death of the donee did not immediately revert to the donor, unless the donee died intestate, or unless, though he made a will, he had made no mention of his interest in the land as of a term of years, but that if he had disposed of it in his will as of a chattel, such disposition was valid. (Bracton, fol. 27 *a*; see Doe dem. Blake, 6 T. R., 291.) This power of disposing of a freehold interest in land must have fallen into disuse after the time of Bracton; for it is quite inconsistent with the doctrine of general occupancy as stated by Littleton, and also with the general rule of law, which prevented freehold interests in land from being disposed of by will, before the Statutes of Wills passed in the reign of Henry VIII. But the Statutes of Wills were limited to estates in fee simple, and no power to devise estates *pur auter vie* existed at law before it was given by the Statute of Frauds.

Since the passing of the Statute of Frauds (29 Car. II. c. 3), general occupancy (with, perhaps, one exception, hereafter mentioned) has ceased to exist. By that statute (s. 12) a man was enabled to devise an estate *pur auter vie* by a will in writing, executed as therein mentioned, and attested by three witnesses; and if no such devise thereof was made, the estate was chargeable in the hands of the heir, if it should come to him by reason of a special occupancy, as assets by descent, as in case of lands in fee-simple; and in case there should be no special occupant thereof, it was declared that it should go to the executors or administrators of the party that had the estate thereof by virtue of the grant, and should be assets in their hands—that is, should be liable to the payment of the testator's or intestate's debts. By the 14 Geo. II. c. 20, s. 9, which recites "that doubts had arisen, where no devise had been made of such estates, to whom the surplus of such estates, after the debts of such deceased owners thereof were fully satisfied, should belong:" it was enacted, "That such estates, *pur auter vie*, in case there was no special occupant thereof, of which no devise should have been made according to the said Act (29 Car. II. c. 3), or so much thereof as should not have been devised, should go, be applied, and distributed, in the same manner as the personal estate of the testator or intestate." These two statutes provided for the case both of a devise being made of an estate *pur auter vie*, and also for the case of the land coming to the heir as special occupant where no devise was made. But an estate *pur auter vie* may be limited either to a man and his heirs, or to a man, his executors and administrators, or to a man simply without mentioning either heirs, executors, or administrators. The Statute of Frauds appears to contemplate the heir only as special occupant, and if there was no devise according to the statute, and no special occupant, which would happen when the estate was limited simply to the grantee, the estate went to the executor or administrator for the payment of debts, and after payment of debts the surplus was distributed, under the act of George II., in the same manner as the testator had directed the distribution of his personal estate, or it went, in case of an intestacy, to the next of kin of the intestate. But when no devise was made according to the statute, and the estate was limited to the grantee, his executors and administrators, inasmuch as the heir could not in that case be special occupant, the question arose, if the executor or administrator could be such occupant, and if he could, the further question arise, who was to have the estate after payment of debts? The proper construction of the two statutes seemed to be that the heir only could be special occupant, and that he alone could take as such. If, then, the land were not devised according to the Statute of Frauds, and there was no special occupant, by reason of the limitation being simply to the grantee, or to him, his executors, and administrators, the executor or administrator would take it under the Statute of Frauds, and distribute it, after payment of debts, under the statute of George II. The executor or administrator took the estate as a freehold, which it is, but in trust for the persons entitled under a will, which was sufficient to pass personal estate, or, in cases of intestacy, in trust for the next of kin. (See the opinions of Lord Redesdale, in Campbell *v.* Sandys, 1 Sch. and Lef., 288; and the opinions of Lord Eldon, in Ripley *v.* Waterworth, 7 Ve., 425.)

If a man dies intestate who is seised of an estate for another's life, and the limitation is such that the estate cannot go to his heir as special occupant, the estate seems open to a general occupancy until an administrator is appointed: but such administrator seems to have a title by relation.

Neither the Statute of Frauds nor that of George II. applied to copyholds, and therefore not to estates *pur auter vie* in copyhold lands.

Estates *pur auter vie*, whether there shall or shall not be any special occupant thereof, and whether the same shall be freehold, customary freehold, tenant right, customary or copyhold, or of any other tenure, and whether the same shall be a corporeal or incorporeal hereditament, are now devisable by a will in writing executed in the manner prescribed by the statute of 1 Vic. c. 26, which repeals, among other clauses, that part of the Statute of Frauds which relates to estates *pur auter vie*, and also the 9th section of 14 Geo. II. c. 20. And if no disposition by will is made of any estate *pur auter vie* of a freehold nature, the same shall be chargeable in the hands of the heir, if it shall come to him by reason of special occupancy, as assets by descent, as in the case of freehold land in fee simple; and in case there shall be no special occupant of any estate *pur auter vie*, it shall go to the executor or administrator; and if the same shall come to the executor or administrator either by reason of a special occupancy or by virtue of that Act, it shall be assets in his hands, and shall go and be applied and distributed in the same manner as the personal estate of the testator or intestate. This statute settles a number of questions, some of which have been already referred to, which were of frequent occurrence, with respect to estates *pur auter vie*.

On the subject of occupancy, the reader may consult Puffendorf, 'Law of Nature and Nations,' iv., c. 6.

OCCUPATIONS OF THE PEOPLE. [Census.]

OCEAN. [Sea.]

OCHRE. Certain impure oxides of iron, of a yellow, red, or brown colour, are employed as pigments, under the name of ochres. They generally contain clay. [Colouring Matters.]

OCTAGON. [Polygons, Regular.]

OCTAHEDRON. [Solids, Regular.]

OCTANS (the instrument commonly called a quadrant, which, when on Hadley's construction, is of the form of an *octant*, or eighth part of a circle), a constellation of Lacaille, situated at the south pole, which it includes. There are no stars of conspicuous brightness in this constellation.

OCTAVE (*Octavus*, Lat.), in Music, the eighth note of the scale the most perfect of concords, whose ratio is 2 : 1, therefore the simplest of all the sounds, except the unison. The harmonics of the octave and unison agree invariably, a coincidence which occurs in no other interval, and these sounds have so close a resemblance, that in combination they are hardly distinguishable the one from the other. The following are the properties, says Rousseau, which so singularly distinguish the octave from all other intervals:— The Octave embraces all the primitive sounds, that is to say, all the original tones and semitones. Hence, after having established a system or series of notes within the limits of an octave, if it be wished to extend this series it will be absolutely necessary to follow the same order in a second octave, in a third, or a fourth, &c., and no sound will be found in any of these but what is, as it were, a recurrence of some one in the first series. It is in virtue of this property in the Octave that the term *Diapason* was applied to it by the Greeks. [Diapason.]

The Octave has also another remarkable property, the same writer observes, namely, that it may be doubled, tripled, and multiplied at pleasure, without changing its nature. This multiplication, however, is limited as relates to its effect on the ear, and an interval of eight octaves, for instance, would be scarcely, if at all, appreciable as such by the auditory organ. A double Octave is less agreeable than a single one; a triple Octave loses still more of its pleasing quality; till, by increasing the distance, the relationship of the sounds becomes nearly undistinguishable.

OCTAVE FLUTE. [Flute.]

OCTOBER, in the year of Romulus, was strictly what its name implies, the eighth month. With us it is the tenth. Suetonius tells us that Domitian, who was born in this month, gave it his own name (Sueton., 'Domit.,' c. 13); but it lasted during his life only (Plutarch, 'Num.,' p. 72; Macrobii, 'Saturnal.,' i. 12). Antoninus Pius, in honour of his wife Faustina, called it "Faustinus" (Julius Capitolinus, c. 10); and the flatterers of Commodus assigned to it one of their patron's epithets, "Invictus." (Ælius Lamprid., ed. Lugd. Bat., 1671, p. 507.) Our Anglo-Saxon ancestors gave it the name of *Winter-fylleth*, the winter full-moon, or winter-beginning, as they reckoned by winters not by years. They also called it *teotha monath*, the tenth month. (Bosworth, 'Sax. Dict.')

OCTYL. [Caprylic Alcohol; *Capryl.*]

OCTYLAMINE. Synonymous with caprylamine. [Caprylic Alcohol.]

OCTYL-CUMINAMIDE $\left(N\left\{\begin{matrix}C_{20}H_{11}O_2\\C_{16}H_{17}\\H\end{matrix}\right.\right)$. An amide formed by the action of chloride of cumyl upon octylamine. [Amides.]

OCTYLENE. [Caprylic Alcohol.]

OCTYLIC ALCOHOL. [Caprylic Alcohol.]

OCTYL-PHOSPHORIC ACID. When octylic alcohol is placed in contact with vitreous phosphoric acid, it forms an acid similar to ethyl-phosphoric acid, and to which the name octyl-phosphoric acid has been given.

OCTYL-SULPHURIC ACID; *Sulphoctylic acid.* Synonymous with sulpho-caprylic acid. [Caprylic Alcohol.]

OCULAR IMAGE. [Eye, in Nat. Hist. Div.]

OCULAR SPECTRA. [Accidental Colours.]

ODE is derived from a Greek word, which signifies a song (ᾠδὴ, ἀοιδὴ), and appears to have been originally applied to any kind of poetry which was written to be sung or accompanied with music. The ode may be regarded as the foundation of lyric poetry, and differs from epic poetry in delineating the poet's own thoughts and feelings, while the latter species of poetry details external circumstances and events. The most celebrated Greek and Roman odes are those of Pindar, Horace, and Anacreon. In English the best odes have perhaps been written by Dryden and Gray. For a further account of this species of poetry the reader is referred to Lyric Poetry.

ODIN. [Scandinavian Mythology.]

ODO'METER (from ὁδὸς, a road, and μέτρον, a measure) is an instrument used for measuring the distances passed over in travelling, and is very nearly the same as that which is called a pedometer: the latter is carried in the pocket of a person on foot or on horseback, and the former is attached to a carriage. Grayson's odometer is a box containing a train of wheel-work, and is attached to one side of a carriage above the axle. There are two dials, one for the driver and the passengers, the other for the proprietor: the object of the apparatus being to record the distance run, as a check upon the honesty of the driver of any hired vehicle. The apparatus belongs to one of the classes or groups described under Numbering Machines.

ODORINE. [Picoline.]

ŒCUMENICAL COUNCILS. [Council, of the Church.]

ŒNANTHIC ACID ($HO,C_{14}H_{13}O_3$). This acid, in combination with oxide of ethyl forming *œnanthic ether* ($C_4H_5O,C_{14}H_{13}O_3$), is found in grape wine, and gives to that liquid its characteristic odour. The ether is obtained on distilling wine itself, or wine lees with water; it is then decomposed with caustic potash, and the œnanthate of potash distilled with sulphuric acid, when œnanthic acid passes over, and congeals at [illegible]° Fahr. into a semi-solid colourless fat, of the consistence of butter. At a higher temperature it melts, is inodorous and tasteless, reddens litmus paper, and easily dissolves in the caustic alkalies, alkaline carbonates, ether, or alcohol. Heat splits œnanthic acid up into water and anhydrous acid; but in other respects it greatly resembles pelargonic acid. M. Fischer has just (1860) announced his belief that the so-called œnanthic acid is merely a mixture of capric and caprylic acids.

ŒNANTHOL, *œnanthylic aldehyd*, or *hydride of œnanthyl* ($C_{14}H_{14}O_2 = C_{14}H_{13}O_2,H$). This substance forms about ten per cent of the products of the destructive distillation of castor oil. It may be purified by agitation with baryta water and re-distillation, and finally obtained dry by digestion over chloride of calcium.

Œnanthol is a colourless liquid, of sp. gr. 0·8271 at 63° Fahr. Its boiling point is 312° Fahr., and vapour density 4·17. It has a penetrating odour, and at first sweet, but afterwards acrid taste. It is soluble in alcohol or ether, but very slightly so in water. It forms a crystalline compound with bisulphite of soda, and is converted into œnanthylic acid by nitric acid, chromic acid, or even by exposure to air.

Metœnanthol is a crystalline body, isomeric with œnanthol. It is produced when œnanthol at 32° Fahr. is mixed with nitric acid at the same temperature, and the whole set aside for twenty-four hours.

Hydride of trichlorœnanthyl ($C_{14}H_{11}Cl_3O_2$) is a heavy oily fluid, resulting from the action of chlorine upon œnanthol.

ŒNANTHYLAMIDE. [ŒNANTHYLIC ACID.]

ŒNANTHYLIC ACID ($HO,C_{14}H_{13}O_3$). This acid is a frequent product of the oxidation of fatty matters by nitric acid. It is most conveniently prepared by heating castor oil with twice its bulk of nitric acid; red fumes are evolved in great abundance at first, but afterwards more moderately, until, at the end of a few hours, the action is complete, and the acid then rises to the surface as an oily layer. It may be rectified with water, and finally dried over anhydrous phosphoric acid.

Œnanthylic acid is a colourless, transparent oil, of agreeable aromatic odour and acrid taste. It is only slightly soluble in water, but readily so in alcohol, ether, or nitric acid. It boils at 298° Fahr., and may be distilled, but suffers partial decomposition during the operation. It does not become solid at 0°. Ignited, it burns with a clear non-smoky flame.

The *œnanthylates* are easily formed by dissolving carbonates in œnanthylic acid. The *potash salt* does not crystallise, but furnishes *anhydrous œnanthylic acid* ($C_{14}H_{13}O_{3}, C_{14}H_{13}O_{3}$) on distilling with oxychloride of phosphorus. *Œnanthylate of copper* crystallises in beautiful green needles, soluble in alcohol, and slightly so in water. *Œnanthylate of baryta* ($BaO,C_{14}H_{13}O_3$) occurs in lamellar crystals. *Œnanthylate of ethyl, or œnanthylic ether*, contains ($C_4H_5O,C_{14}H_{13}O_3$).

Œnanthylamide ($NH_2(C_{14}H_{13}O_2)$) is produced by the reaction of œnanthylic acid and ammonia. It crystallises from alcohol in little plates.

ŒNANTHYLO-BENZOIC ANHYDRIDE $\left(\begin{matrix}C_{14}H_{13}O_2\\C_{14}H_5O_2\end{matrix}\right\}O_2\Big)$. [ANHYDRIDES.]

ŒNANTHYLO-CUMINIC ANHYDRIDE. [ANHYDRIDES, *Cumino-œnanthylic*.]

OTHYL. Synonymous with acetyl. In addition to the compounds of this negative radical alluded to under ACETYL, it may be here mentioned that bromal is regarded as a compound of othyl; its composition is analogous to that of chloral, the chlorine of the latter being replaced by bromine. The following is a list of other compounds of othyl.

Hydride of othyl or aldehyde . . . . . $\left.\begin{matrix}C_4H_3O_2\\H\end{matrix}\right\}$

Aldehydide of ammonium . . . . . . $\left.\begin{matrix}C_4H_3O_2\\NH_4\end{matrix}\right\}$

Potassium aldehyde . . . . $\left.\begin{matrix}C_4H_3O_2\\K\end{matrix}\right\}$

OTHYL, HYDRIDE OF. [OTHYL.]

OFFERINGS, OBLATIONS, and OBVENTIONS, are not only those small customary sums paid at Easter, but also the customary payments for marriages, christenings, churchings, and burials. By 2 & 3 Ed. VI. c. 13, "all persons which by the laws and customs ought to make or pay their offerings, shall yearly well and truly content and pay the same to the parson, vicar, proprietor, or their deputies or farmers, of the parishes where they shall dwell or abide; and that at such four offering-days as at any time heretofore within the space of four years last past hath been used and accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter then next following." The four offering days above spoken of were Christmas, Easter, Whitsuntide, and the feast of the dedication of the parish church. It is directed by the rubric, at the end of the Communion Service, that "yearly at Easter, every parishioner shall reckon with the parson, vicar, or curate, or his or their deputy or deputies, and pay to them or him all ecclesiastical duties accustomably due then at that time to be paid." Easter offerings are due of common right, as well as by custom. (Bunb. 173, 188.) Thus, in Carthew *v.* Edwards, Trin. 1749, in the Exchequer, it was held that Easter offerings were due of common right, after the rate of 2*d.* a head for every person in the family of sixteen years of age and upwards. But by custom the sum may be more. In London 4*d.* a-head is usually claimed.

Surplice-fees are payable for every marriage, whether by banns or licence; and for every funeral, churching, or christening, according to the custom of the parish. Mortuaries are claimed on the death of each person in a parish, according to value of property left, but not to a greater amount than 10*s.*

(Burn, *Ecclesiastical Law*; Blackst., *Comm.*, Mr. Kerr's ed. vol. iii., c. 7.)

OFFICE FOUND. By the common law of England, where the crown is entitled, upon the occurrence of certain events, to take possession of real or personal property previously belonging to a subject, the facts upon which the right accrues must be first ascertained by an inquisition or inquest of office. This inquiry is executed by some officer of the crown, such as the escheator, coroner, or sheriff, or by persons specially commissioned for the purpose, and the facts are ascertained by a jury of an indeterminate number, but consisting usually, though not necessarily, of twelve men. Such inquests were much more frequent before the abolition of military tenures, when inquisitions *post mortem* were instituted upon the death of any of the tenants of the crown, to inquire of what lands he died possessed, and of other matters tending to establish the right of the lord respecting the property of the deceased. [JURY.] When an inquisition of this kind has been executed and returned, it is said to be *an office found*. Thus where treasure has been discovered under circumstances which do not give it to the owner of the land, an inquest is held, and the crown, upon office found, takes it; and where a person of illegitimate birth dies intestate, the sovereign (if he is the immediate lord of the fee), upon office found, is entitled to all his land: in the latter case however the land is generally granted again to some person or persons who can make out the most reasonable claim to it. So also the verdict of a jury upon a coroner's inquest, declaring a person to have died *ut felo de se*, is an office found, upon which the crown becomes entitled to take possession of the property of the deceased.

OFFICE, HOLY (*Sanctum Officium*). [INQUISITION.]

OFFSETS are lines drawn perpendicular to the chord of an arc, or the longest base of an irregular polygon, from points in the arc, or corners of the polygon. By means of these offsets the area contained between the chord and arc can be found with sufficient nearness. We mention this well-known term of surveying to direct attention to the article QUADRATURES, METHOD OF, which contains the set of successive approximations of which the surveyor's process is the first and rudest step.

OIL COLOURS. [PAINTING, HOUSE.]

OIL OF TURPENTINE. [TURPENTINE.]

OIL OF VITRIOL. [SULPHUR; *Sulphuric Acid.*]

OIL PAINTING. [PAINTING.]

OILS, MANUFACTURE OF. The manufacture of animal oils, such as that of the whale, is simple. The *blubber*, or fat from which the oil is procured, is usually cut into small pieces and packed in casks soon after it is taken from the whale; it is then brought home in a half-putrid state, and is emptied into a large wooden vessel or receiver, capable of holding several tons. From this receiver the decomposing fat is conducted, after settling for a few hours, into a copper boiler, in which the separation of the fluid from the solid portions of the blubber is completed by the application of heat. From the boiler the oil flows through a kind of filter of brushwood, which detains the grosser impurities, into coolers, from which, when quite cold, it may be drawn off into casks. Various chemical processes are employed for purifying whale oil and diminishing its unpleasant smell. The quantity of oil obtained is about four-fifths that of the blubber used. In the South-Sea fishery it is found advisable to boil the blubber on board the whaling vessels, and to bring home the oil in the liquid state in casks. In this process, as commonly performed, the oil is very imperfectly extracted from the blubber, and the *scraps*, or solid portions which remain, are used as fuel under the *try-pots*, or boilers; by which arrangement the oil that remains in them is not only destroyed, but the substance becomes, from its great inflammability, a source of serious danger. To obviate these evils some ships are provided with powerful screw-presses for squeezing out whatever oil may remain after the process of boiling the blubber, and thus materially increasing the produce. Hebert, in the 'Engineer's and Mechanic's Encyclopaedia,' gives an engraving and description of such a press; in which the blubber scraps, while yet warm, are put into a hollow cylinder, and compressed by a piston brought down upon them with a great force. The oil escapes through holes in the bottom of the cylinder, between which and the blubber is laid a mattress of wickerwork, to prevent the blubber from choking up the holes. This press is the invention of Mr. John Blythe, of Limehouse.

Olive oil differs from most vegetable expressed oils in being extracted from the soft fleshy pericarp; whereas such oils are usually procured from the seeds only. The manufacture is simple, and is usually conducted with very rude machinery. In the neighbourhood of Aix, in Provence, the first and finest oil is obtained by crushing the olives in a kind of mill, in which the crushing-stones are so mounted as not to break the stones of the fruit, but simply to crush the pulp. The mass thus bruised is put into *cabas*, or bags made of bulrush-matting, or of coarse canvas, which are piled or laid upon one another to the number of about a score, and exposed to gradual compression in a screw-press; the oil which flows from the cabas, which is the pure virgin oil, is conducted by channels into casks or stone cisterns partly filled with water, on the surface of which it floats so that it may be readily collected by skimming. When the oil ceases to flow, the mass of pulp is taken out of the bags, mixed with boiling water, and treated as before, but with an increase of pressure. The second quality of oil thus procured is quite fit for table use when fresh, but is apt to become rancid by keeping. After skimming off the oil which accumulates on the surface, the subjacent water still retains a good deal of oil, by the intervention of the mucilage; but after long repose in a large cistern the oil and water separate, and the water may be drawn off from below. This oil, however, is of very inferior quality, and can only be used for factory purposes. A still coarser kind of oil is finally procured by crushing the marc, or solid residue, in a mill, so as to break the stones, boiling it with water, and re-pressing it. All the oil must be *fined* by keeping in clean tuns, in an apartment heated to at least 60° Fahr., for twenty days; after which it is run off into strong casks, cooled in a cellar, and then sent into the market.

Olive oil is refined, for the use of watchmakers, in the following way. Into a bottle or phial containing the oil, a slip of sheet-lead is immersed, and the bottle is placed at a window, where it may receive the rays of the sun. The oil by degrees gets covered with a curdy mass, which after some time settles to the bottom, while itself becomes limpid and colourless. As soon as the lead ceases to separate any more of that white substance, the oil is decanted off into another phial for use.

Passing over the processes of manufacture of many kinds of oil of less importance, we proceed to take linseed-oil, or the oil extracted from the seeds of the flax-plant, as an illustration of the manufacture of oil from seeds. "Linseed, rape-seed, poppy-seeds, and other oleiferous seeds were," Dr. Ure observes, "formerly treated for the extraction of their oil, by pounding in hard wooden mortars with pestles shod with iron, set in motion by cams driven by a shaft turned with horse or water-power; then the triturated seed was put into woollen bags, which were wrapped up in hair-cloths, and squeezed between upright wedges in press-boxes, by the impulsion of vertical rams driven also by a cam mechanism." In the best mills on the old construction, he adds, the cakes of crushed seeds obtained by this first wedge-pressure were ground anew upon the bed of an edge-mill, and subjected to a second pressure, with the aid of heat. "These mortars and presses," he states, "constitute what are called Dutch mills: they are still in very general use both in this country and on the Continent, and are by many persons supposed to be preferable to the hydraulic presses."

Owing to the extreme hardness and smoothness of the seeds of flax and hemp, and to the circumstance that the fragments of their shells, however broken, form minute concavities which will retain the oil unless a greater pressure be applied than could be given by an ordinary screw-press, the presses employed for extracting oil from such seeds differ materially from those used in crushing olives and other comparatively soft oleaginous substances. Hence it is that the wedge-press and Bramah's hydraulic press have been introduced for the purpose. Of these two powerful machines some manufacturers prefer the former, believing that the same degree of pressure is more efficient when imparted by means of sudden impulses or blows upon the end of a wedge, than when it is applied gradually and steadily as in the hydraulic press. In the wedge-press, of which there are many varieties, the crushed seeds are put into bags of hair-cloth or some similar material, and these bags are then placed between plates of iron united together like the covers of a book, or between boards or blocks of wood, within a very strong and massive framework. The small end of a wedge is then introduced in such a way between the plates or boards that, when it is driven down by the blows of a ram or pestle, it may compress the bags with enormous force. The driving of the wedges is continued until they are so tight that the pestle rebounds from them three times, when they are judged to be sufficiently driven. The use of the hydraulic press instead of this apparatus needs no minute explanation. Some of these act horizontally, the bags being, as in the wedge-press, placed vertically, and separated from one another by cast-iron plates; but in others the bags are piled upon one another in cast-iron cases, and placed in a vertical press. The seed is put into bags of flannel or of horsehair. Among other advantages it is stated that the hydraulic or hydrostatic press requires less space than a stamping-mill which could do the same work, and that the hairs and bags are found to last longer with it than with the old machine.

A mode much adopted in this country, of obtaining linseed oil, we shall now describe. As the hardness and smoothness of the seed gives it a tendency to slide away unbroken under the rolling action of the millstones by which they are ground, it is desirable, before taking it to the grinding-mill, to bruise or crush the seed by causing it to fall from a hopper between two iron crushing-rollers, placed side by side, and capable of being pressed against each other with any determinate degree of force; but the use of such rollers is by no means universal, the seeds being, in many cases, submitted to the grinding-mill without any such preparation. This mill, which is sometimes called an *edge-mill*, consists of a pair of stones, technically called *running-stones*, or *runners*, usually made of granite, resembling grindstones in shape, and from five to seven feet or upwards in diameter, so mounted as to roll round in a circular path of small diameter upon a solid horizontal bed of stone or iron laid beneath them. These stones, which roll round the bed from thirty to thirty-six times in a minute, are sometimes hooped with iron, though many prefer the rough surface of the granite, which may be re-dressed with a hammer as often as is needful. They grind the seed partly by their weight, which often amounts to three tons each, and partly by the peculiar rubbing motion which arises from the circumstance that the outer edge of the stone has to perform a larger circuit than the inner, although the two must of course revolve round the axle at one and the same speed. The action is therefore similar to that of a cone when forced to roll onward in a straight path. The two running-stones are mounted on the same horizontal axis, but at rather different distances from the central vertical shaft or axis round which they roll, so that they do not follow one another in precisely the same path on the bed of this mill. The bed is surrounded by a rim which prevents the seeds from being scattered; and the revolving framework in which the running-stones are mounted carries also two rakes or sweeps, which collect and lay the seeds in a ridge along the circular path of the runners. By this means the seeds are reduced, by the partial expression of the oil, to a pasty mass, from which a limited quantity of very fine *cold-drawn* oil may be obtained by the simple action of the press.

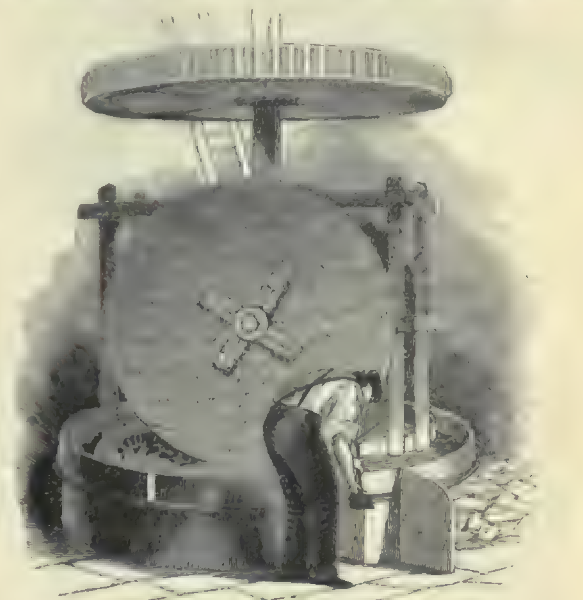


Fig. 1.—Linseed Crushing.

We have hitherto spoken only of the extraction of the finest oil, without heat. The application of heat before pressing is however necessary for obtaining the principal supply of oil. The precise order of the several operations, as well as the nature of the machinery employed, differs in different manufactories. In some establishments the oil-cakes, or solid contents of the bags, which remain after the first cold pressing, are taken out of the bags, broken to pieces, and put into mortars to be pounded by pestles worked by machinery. There the paste is again broken down, and the parenchyma of the seed reduced to a fine meal; thus free egress is allowed to the oil from every vesicle in which it is contained; but it is now rendered much more clammy by the forcible mixture of the mucilage, and even of the fine parts of the meal. When sufficiently heated it is removed to a *chauffer*, or circular copper-pan; in which, while it is kept continually stirred by machinery, it is heated to about the temperature of melting bees-wax, either by a charcoal fire, or according to a more recent practice, by steam. It is then, while hot, put into the bags and subjected to a second pressing; and in some cases the like operations are repeated a third time, by which a further quantity of oil, but of inferior quality, is produced. Sometimes the produce of oil is increased by mixing a little water with the paste; but this practice is considered to impair the quality of the oil. The oil-cakes which remain after the last process are used as food for cattle, and for various other agricultural purposes; but of course the cakes vary greatly in richness according to the degree in which they have been divested of oil. There are small mills in Holland which have no other employment than extracting oil from the cakes which they purchase from the French and Brabanters, after passing the process of their mills: a clear indication of the superiority of the Dutch practice over that of their neighbours. In some of the Dutch mills, the produce is increased by the application of moderate heat during the grinding process, by enclosing a little furnace in the bed upon which the running stones roll; but the utmost care is necessary to prevent the heat from becoming too considerable,

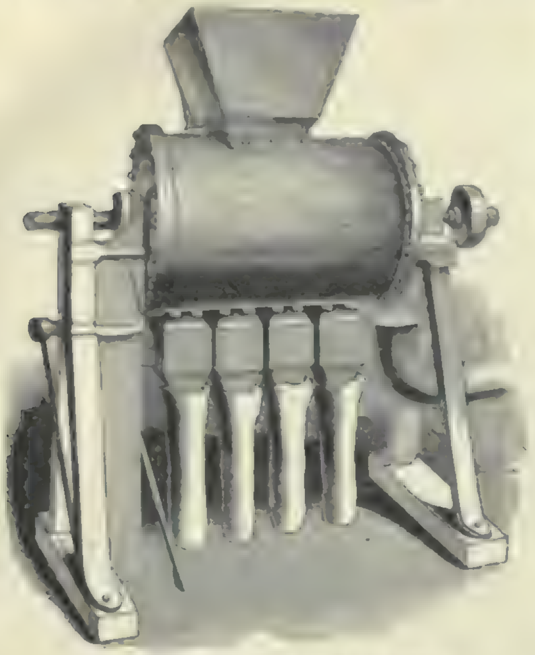

Fig. 2.—Ground Linseed falling into bags.

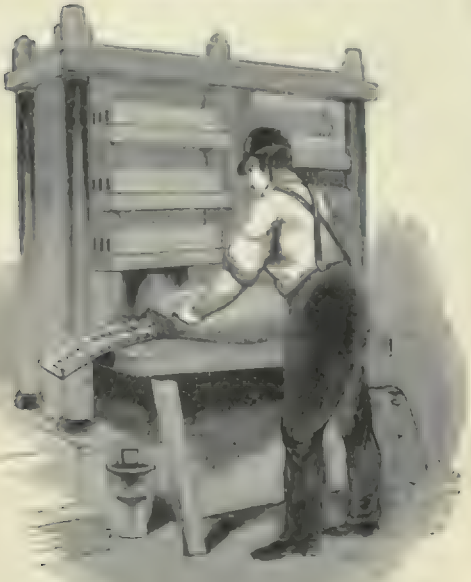

Fig. 3.—Bags of Linseed in the Hydraulic Press.

as it causes the oil to dissolve too much of the fermentable substance of the seed, and exposes it to the risk of soon growing very rancid. When the seed is very dry the process of grinding may be facilitated by the addition of a little water. The oil produced by the above process needs little further attention. If left in a cistern, as it is by the Dutch manufacturers, the parenchymatous part, which inevitably passes away with the oil in some degree in the operation of pressing, will gradually subside, and the oil may be drawn off at various levels, of different degrees of purity; the bottom being at length removed to a deep and narrow cistern, where it should be left a considerable time for the dregs to subside.

The annexed cuts represent three stages in the process of obtaining linseed oil by the hydraulic press; namely, the crushing of the seeds between edge rollers, the falling of the seeds into bags after grinding; and the piling of the bags in the hydraulic press.

Mr. Samuelson, in a paper read before the Society of Mechanical Engineers, in 1858, entered fully into the respective merits of the different modes of expressing linseed oil. The latest and best arrangement he stated to be that of Blundell's double hydrostatic press, with two presses and two pumps, all connected by hydraulic tubing. The larger pump is weighted to 740 lbs. per square inch pressure; the smaller to 5540 lb. Each press works four bags of seed at once. A pressure of 40 tons is brought to bear on the seed in the first instance; and this is succeeded by one of 300 tons. Each press produces 36 cwt. of oil cake per day of 11 hours, and 14 cwt. of oil. It is a curious feature in this new form of hydraulic press, that it is worked with limpid oil instead of with water. Mr. Samuelson stated that there are now more than one million quarters of linseed pressed for oil annually in England; that two-thirds of the whole trade is centred at Hull; and that the produce comes out as about 144,000 tons of oil-cake and 56,000 tons of linseed oil.

Linseed oil is used principally as a vehicle for mixing oil-colours for painting, but it is also valuable in several branches of manufacturing industry, and, in a refined or purified state in some medicinal preparations. Being a fat or unctuous oil, it is slow in drying, and as this is a great inconvenience for some purposes in painting, it is sometimes converted into *drying oil* by boiling it with sugar of lead, white vitriol, red lead, or other substances which possess similar properties. The common kinds of drying oil are generally known by the name of *boiled oil*.

The trade in *lard oil* in America is so remarkable, in its origin and its nature, as to deserve a few lines of notice. When the British commissioners were at the New York Exhibition in 1853, they obtained information, among other things, concerning what in America is called *hog industry*. About the year 1830, farmers in the central states, especially Ohio, unprovided with cheap means of sending their produce to market (for there were no railways in those days), hit upon the plan of converting their corn into living meat, which could "walk itself off to market,"—in other words, fattening hogs. The trade grew year by year; until at length the city of Cincinnati soon became the centre of vast operations. The farmers in the country districts rear hogs, from 100 to 1000 on each farm. Drovers or jobbers come and purchase them, and drive them to Cincinnati, where they sell them to capitalists. These capitalists engage the services of killers, salters, curers, and packers, who keep large establishments in and near the city. The hogs, when still in the farmers' hands, are allowed to roam about in the woods, and feed themselves on acorns and beech-mast; but when the time for sale is approaching, they are called in, and fattened with an abundance of corn. Their average age at the time of sale is about 15 months, and average weight 200 lbs. When they arrive at the killing establishments, they are driven up an inclined plane to the upper floor or story, where they are penned for a short time. They next descend to the killing-room, where a poleaxe and a knife speedily end their existence. The dead bodies are at once thrown into a huge scalding tank, where the heat of hot water brings the outer skin to a state fit for subsequent operations. They are quickly passed to another room, where all refuse, from within and without the animal, is removed. All this is the work of the killers, who find a useful market for everything—skin, bristles, fat, intestines, blood, hoofs, &c.: nothing is wasted. In 1852 there were ten vast slaughtering establishments in Cincinnati, at which no less than 400,000 hogs, weighing 80,000,000 lbs., were slaughtered in twelve months. From the slaughterers, the carcases go to the curers and packers. Here the hogs are cut up into joints with surprising rapidity. Two men, the commissioners say, will cut up 850 hogs in a day of 13 hours, with two other men to carry and lift the carcases, and a fifth to trim the 1700 hams. The hams and shoulders are salted and cured; the middle pieces are salted, to make pickled pork, and packed in barrels for the navy and for foreign trade. The heads, the trimmings, various other parts, and sometimes (in a dull state of the provision market), nearly the whole carcase, are *rendered*, or digested in steam tanks to get out the fat in the form of lard. In one establishment alone, 3,000,000 lbs. of hog's lard were thus obtained in 1852. The lard is to some extent used as a substitute for butter, in cooking and culinary operations; but it is much more extensively applied to the production of *lard-oil* and *stearine*. When pressed in a hair-cloth bag, the lard yields from 40 to 70 per cent. of oil; the rest is a white solid stearine. The stearine is used for candles. The lard-oil, after being refined at a temperature of 200° Fahr., is used for soap-making, and for cheapening finer oils. In 1852, there were more than thirty lard-oil factories in Cincinnati alone. This city is, as we have said, the greatest centre of the trade; but it is not the only one. In eight of the middle states of the Union, there were, in the season 1852–3, more than 2,000,000 hogs cut up for meat, oil, stearine, &c.—the killing and salting being generally effected during the winter months.

The oil trade of this country is now a very considerable one. In 1859, the exports included (in round numbers) 20,000 tuns of train oil, blubber, and spermaceti; 20,000 tuns of olive oil; 11,000 tuns of various kinds of seed oil; 185,000 cwts. of cocoa-nut oil; and the enormous quantity of 686,000 cwts. of palm oil. Few circumstances, in connection with the recent history of our manufactures, are more important or interesting than the rapid increase in the palm-oil trade. The collecting and shipping of this product are the work of free persons in Africa; English gold finds its way thither in exchange; and it is possible (though the evidences of the fact are as yet very few) that the slave trade may be lessened by this gradual familiarising of the natives with the commercial dealings of Europe. The imports of whale oil are decaying, partly on account of the scarcity of whales in the North Atlantic, and partly owing to the increase in the use of vegetable oils. Of the seed oils, a large proportion is now Colza, or rape-seed oil, imported for use in lamps. In 1859 our farmers used 95,000 tons of oil cake, in addition to that obtained from oil-mills in this country. Of the 1,270,000 quarters of linseed imported, all but a small proportion was pressed for oil, the seed for sowing being comparatively small in quantity. In the same year, England exported nearly 8,000,000 gallons of seed oil; this was nearly all linseed oil, and was probably mostly for use in house-painting.

OILS, ESSENTIAL. [Essential Oils.]

OILS, FIXED. [Fixed Oils.]

OILS, VOLATILE. [Essential Oils.]

O'LEA EUROPÆA, *Medical Properties of.* A peculiar resiniform, balsamic exudation from the tree, the leaves, the fruit, and oil from the fruit, of this tree are all in use, but in Britain the oil only is officinal. The resin contains a peculiar matter termed *olivile*, a brown resin, and benzoic acid. The leaves have a peculiar crystalline febrifuge substance, useful against intermittents. ('Pharmacopœia.') The olive oil is itself used to adulterate cod liver oil; but this is in every way disadvantageous to the patient, as it is quite as apt to cause nausea, and is by no means productive of so much good as cod liver oil. (See 'Lectures on Pulmonary Consumption,' by Theophilus Thompson, p. 88.)

Olive-oil, on account of its high price, is frequently adulterated with poppy or rape oil. The former may be easily detected, if present in the proportion of only 1 per cent., as it retards the solidification of the oil, when a mixture, consisting of 9 parts of nitric and 3 parts of hyponitrous acid, is added to 100 parts of the suspected oil. The presence of metals may be detected by sulphuretted hydrogen. For various means of applying these and other tests, see Thomson's 'Organic Chemistry—Vegetable Substances,' p. 435; and notes in 'Edinburgh Pharmacopœia.'

Olive-oil is used in medicine as an emollient, and to form cerates and plasters. It is also used in the manufacture of soap. The finest kind is much employed with various articles of food, particularly in the countries where it is produced.

As this oil becomes viscid more slowly than any other vegetable oil, it is used, after being purified, by watch-makers.

OLEATES. [Oleic Acid.]

OLEENE. [Hexylene.]

OLEFIANT GAS. [Ethylene.]

OLEIC ACID. As oleate of glycerin, or olein, this acid forms the greater portion of all drying oils and the fluid part of nearly all fats.

Olein or *elain* ($C_{114}H_{104}O_{12}$). It was first observed by Chevreul that expressed oils and different kinds of fat usually contain two oils of different degrees of fusibility, or in other words, two different fatty substances; so that on cooling any expressed oil, one part of it became solid, while another portion retained its fluidity. In consequence of this observation he concluded that all expressed oils are similarly constituted; to the less fusible oil he gave the name of *stearin* (from στέαρ, suet), and the more fusible he termed *elain* (from ἔλαιον, oil), which was afterwards changed to *olein*.

Several methods have been proposed for separating these two substances. When olive oil, for example, is exposed to a low temperature, a portion of it becomes solid, and the remainder retains its fluid form; the former is *stearin*, or *margarin*, and the latter *olein*; these are separated by absorbing the liquid part by blotting-paper, and pressing the solid portion between folds of this paper till it ceases to render it greasy. The olein which the paper has absorbed is then to be separated from it by boiling it in water, on which the olein floats, and the paper sinks.

Olein has scarcely any taste or smell when procured from oils which possess these properties only in a slight degree. Its specific gravity is 0·98, it solidifies at 27° Fahr., and crystallises in needles. In water it is quite insoluble, but alcohol takes it up largely when boiling; by the alkalies potash and soda it is readily saponified, and during this operation oleic acid is formed by a new arrangement of the elements of the olein and their action on the elements of water; and these changes occur without the evolution of any gaseous matter.

On account of the very low temperature at which olein congeals, it is well adapted for lubricating the wheels of watches, and its value in this respect is enhanced by its not readily becoming rancid by the action of the air.

Although olein is frequently regarded simply as teroleate of glycerin, its constitution is more correctly expressed by regarding it as glycerin $\left.\begin{matrix}C_6H_5'''\\H_3\end{matrix}\right\}O_6$ in which three equivalents of hydrogen are replaced by three of the acid radical ($C_{36}H_{33}O_2$). Berthelot has indeed succeeded in forming this compound (*terolein*) artificially, as well as *diolein* and *monolein*. The processes he adopted have already been described under Glycerin; the following formulæ will however show the relations the compounds in question bear to each other:—

$$\underbrace{\left.\begin{matrix}C_6H_5'''\\H\\H\\H\end{matrix}\right\}O_6}_{\text{Glycerin.}}\qquad\underbrace{\left.\begin{matrix}C_6H_5'''\\C_{36}H_{33}O_2\\H\\H\end{matrix}\right\}O_6}_{\text{Monolein.}}\qquad\underbrace{\left.\begin{matrix}C_6H_5'''\\C_{36}H_{33}O_2\\C_{36}H_{33}O_2\\H\end{matrix}\right\}O_6}_{\text{Diolein.}}\qquad\underbrace{\left.\begin{matrix}C_6H_5'''\\C_{36}H_{33}O_2\\C_{36}H_{33}O_2\\C_{36}H_{33}O_2\end{matrix}\right\}O_6}_{\text{Terolein.}}$$

Elaidin is a solid modification of olein, and is produced when the latter is subjected to the influence of peroxide of nitrogen. [Elaidin.]

Linolein is the name given to the olein of linseed oil; it contains *linoleic acid* ($C_{46}H_{39}O_8$), differing apparently from oleic acid, but requiring farther investigation.

Oleic acid ($HO, C_{36}H_{33}O_3$). The preparation of this acid in the pure state is not an easy matter. Olein obtained in the manner above described still contains small quantities of margarin and stearin, and on saponification with an alkali yields margarate and stearate as well as oleate of the base. One of the best methods consists in saponifying with oxide of lead, digesting the resulting salts in ether for twenty-four hours, whereby oleate of lead only is dissolved; the oleic acid separated from the latter salt is super-saturated with ammonia, precipitated by chloride of barium, the oleate of baryta dried and boiled with alcohol, and the crystalline plates deposited on cooling finally decomposed by tartaric acid, when pure oleic acid separates.

Pure oleic acid is colourless, inodorous and tasteless. At about 40° Fahr. it solidifies into a hard white mass of acicular crystals, but at temperatures above 57° remains as a limpid oleaginous liquid, insoluble in water but soluble in alcohol or ether. It rapidly absorbs oxygen from the air, acquires a rancid smell and taste, turns litmus paper red, and has its point of solidification gradually lowered to below the zero of Fahrenheit's scale. By heat oleic acid is broken up into several gaseous and liquid bodies; among the latter is sebacic acid, a matter not obtained in the destructive distillation of the other oily acids.

It follows from what has been stated of the mode in which oleic acid is procured, that it enters largely into the composition of soaps, forming with potash soft soap, and with soda hard soap.

The *Oleates* in general are not crystallisable salts; and those which are not altogether insoluble are mucilaginous before drying; they are usually very fusible.

Oleate of Potash.—This salt has a bitter alkaline taste. When mixed with twice its weight of water, it swells and forms a transparent jelly; when this quantity of water is doubled, a syrupy liquor is obtained. A still larger quantity of water does not render it turbid, but after a considerable time a mucilaginous superoleate of potash separates. Alcohol dissolves its own weight of oleate of potash, when heated to 124° Fahr. and it solidifies on cooling; 100 parts of boiling ether dissolve 3·43 parts, and the solution remains fluid when cold.

Bi-oleate of Potash may also be formed; it is soluble in water and in alcohol both hot and cold, and the solution reddens litmus.

Oleate of Soda.—Has a slight smell, and a slightly alkaline taste. Cold water dissolves 1-10th of its weight.

Oleate of Baryta ($C_{36}H_{33}BaO_4$) is insipid, and insoluble in water. Boiling alcohol dissolves only a small quantity. It is soluble in oleic acid.

Oleate of Magnesia—Has the form of semi-translucent white grains, which soften between the fingers.

Oleate of Copper.—This salt is green. It melts when exposed to the heat of the sun.

Oleate of Lead.—The neutral oleate is prepared in the moist way. It melts between 144° and 153° Fahr. Alcohol and ether dissolve it slowly when cold and rapidly when hot, without altering its neutrality.

Superoleate of Lead.—This salt is liquid at 75° Fahr., and below this temperature becomes an adhesive mass. Boiling alcohol dissolves a little of it, and deposits a neutral salt on cooling. Oil of turpentine and oil of petroleum dissolve both it and the neutral oleate.

Oleate of Methyl ($C_{36}H_{33}(C^2H_3)O_4$) has a specific gravity of 0·879 at 65° Fahr.

Oleate of Ethyl or *oleic ether* ($C_{36}H_{33}(C_4H_5)O_4$) is formed on passing a rapid current of hydrochloric acid gas into a solution of oleic acid in three times its bulk of alcohol. It is colourless, very soluble in alcohol, and has a specific gravity of 0·871 at 65° Fahr.

Sulpholeic Acid occurs among the products of the action of concentrated sulphuric acid upon olein; cold water decomposes a part of it with production of *metaoleic acid*, and the remainder on boiling is converted into *hydroleic acid*.

Chloroleic Acid ($C_{36}H_{32}Cl_2O_4$) is produced by the action of chlorine upon oleic acid. It is liquid at ordinary temperatures, has a brown tint and sp. gr. 1·082 at 46° Fahr. Its boiling point is 374° Fahr.

Bromoleic acid ($C_{36}H_{32}Br_2O_4$) much resembles chloroleic acid. Its sp. gr. is 1·272; boiling point 392° Fahr.

Elaidic Acid bears the same relation to oleic acid that elaidin does to olein; it may in fact simply be considered as a solid modification of oleic acid. It is produced, or rather induced, by the presence of a small quantity of peroxide of nitrogen. The oleic acid operated upon neither changes its composition nor its atomic weight; a small quantity is however acted upon, as traces of an oily body and of ammonia are generated, and it is not improbable that these communicate molecular motion to the particles of the oleic acid.

Elaidic acid melts at about 113° Fahr. It is soluble in ether or alcohol, and by spontaneous evaporation is deposited in beautiful pearly scales resembling benzoic acid. It is volatile, and may be distilled with but little alteration. Maintained at 150° Fahr. for some time it absorbs oxygen, acquires a disagreeable rancid odour, is converted into a liquid, and is no longer solidifiable by peroxide of nitrogen. Like oleic acid, it yields palmitic and acetic acid when fused with hydrate of potash.

Elaidic acid is of course produced when oleic acid or olive oil is acted upon by nitric acid or nitrate of mercury, the ultimate products of the action of excess of strong nitric acid are, however, acetic acid, propionic acid, butyric acid and the whole of the associated acids of the homologous series $CnHnO_4$, up to capric acid inclusive; as well as four terms of the dibasic acid series, $2HO,CnHn_{-2}O_6$, namely, suberic, pimelic, adipic and lipic acids.

The *elaidates* have the same composition as the oleates. Those of the alkalies crystallise, and are soluble in water. *Elaidate of silver* is a white voluminous precipitate containing ($C_{36}H_{33}AgO_4$). *Elaidate of methyl* has the composition $C_{36}H_{33},C_2H_3O_4$. *Elaidate of ethyl* or *elaidic ether* ($C_{36}H_{33}(C_4H_5)O_4$) is a colourless, inodorous, tasteless oil of sp. gr. 0.868 at 65° Fahr. Boiling point about 590° Fahr.

OLEIN. [Oleic Acid.]

OLEOPHOSPHORIC ACID. An oily matter contained in the human brain, chiefly in combination with soda. According to Gobley it is also present in the yolk of egg. It is insoluble in water, but soluble in boiling alcohol and in ether. Alkalies break it up into phosphoric acid, oleic acid and glycerin. It has not yet been obtained in a state sufficiently pure for analysis; according to Frémy it contains from one and a half to two per cent. of phosphorus.

OLE'RON, LAWS OF. The laws, or constitutions, or judgments of Oleron, are a capitulary of ancient marine customs written in old French, and bearing the name of Oleron for several centuries, because tradition points to the island so called as the place of their original promulgation. An ancient copy of these laws is to be found in the 'Black Book' of the Admiralty, the original of which is supposed to be in the Bodleian Library; but they are not there called the Laws of Oleron, nor is there any reference in the laws themselves, or in the book which contains them, to their origin or history. They are not unfrequently appended to ancient editions of the 'Coutumier' of Normandy under the title of 'Les Jugemens de la Mer:' in Cleirac's edition of the 'Us et Coutumes de la Mer' they are given, without any description of the book or place from whence they are taken, under the name of 'Roole des Jugemens d'Oleron.' They are generally referred to by French writers on maritime law as 'Jugemens d'Oleron.' The copies of these laws however published by Cleirac, and those appended to the 'Coutumier de Normandie,' differ materially from each other, and also from that in the 'Black Book' of the Admiralty, though many of the articles are almost verbally the same in all. They relate to the rights and duties of ship-owners and mariners, maritime contracts, port and custom laws, and losses at sea; but are chiefly remarkable at the present day from the circumstance that they were for several centuries adopted by all the nations of Europe as the foundation of their maritime laws.

It has been generally stated by English law writers that the laws of Oleron were compiled by Richard I. in the island of Oleron, on his return from the Holy Land. This statement, which is given by Coke, Selden, Hale, Prynne, Blackstone, Reeve, and several English writers on maritime law, furnishes a curious instance of the readiness with which historical errors are propagated when one writer makes his assertions respecting facts from the statements of another without thought or examination. There is scarcely any fact in history more entirely settled, and few more notorious, than that Richard I., in returning from the Holy Land, was shipwrecked in the Adriatic, near Venice, and immediately taken by Leopold, duke of Austria, and detained a prisoner in Germany ('Fœdera,' vol. i., p. 70); and there is good evidence that at the expiration of his captivity he returned home through Flanders, without touching upon his French dominions. (Hoveden.) It is equally clear, from the account of Hoveden and other chroniclers, that on his way to the East he travelled by land through France, and embarked at Marseille for Sicily. There is therefore not the slightest foundation for the statement which has been referred to; and indeed the only evidence that they were the work of Richard at all is found in what Sir Edward Coke calls a "notable" record in the Tower (4 Inst., 144), which record is also mentioned by Selden in his 'Mare Clausum' (lib. ii., cap. 24). The part of this record however in which these laws are noticed is dated in the reign of Edward III., and consequently 150 years after Richard's time; and the document appears hardly to deserve the name of a record, being merely a roll, consisting of detached membranes, relating to maritime affairs of different reigns, miscellaneously thrown together, and without any formal date or description, or anything to give them the authority of a judicial act. (Luders's 'Inquiry into the Origin of the Laws of Oleron.') This document contains the following passage, from which the story, ascribing this piece of legislation to Richard I. has sprung:—"Quæ quidem leges et statuta per Dominum Ricardum quondam Regem Angliæ, in reditu suo de Terrâ Sanctâ, correcta fuerunt, interpretata, declarata, et in insulâ Oleron publicata, et nominata in Gallicâ linguâ La Ley Olerum." On the other hand, there are strong reasons for attributing to these ordinances a later date than the reign of Richard I., the principal of which are:—1, that they are written in the French language; whereas in the reign of Richard I. all laws of royal ordinance, both in the king's French dominions and in England, were written and promulgated in Latin; 2, that if they had been promulgated in England before the time of Bracton, Britton, and Fleta, they must have been mentioned by those authors; and 3, that the original historians of the reign of Richard I. (though sufficiently ready to record his merits) never mention this part of his legislation.

Mr. Luders conjectures that these laws did not proceed from any royal ordinance; but that the men of Oleron, who had corporate privileges granted to them by the name of "Burgenses de Olerone," in the reign of John ('Fœdera,' vol. i., pp. 111, 112), and had very considerable trade as early as the 12th century, may have collected adjudged cases upon the laws of the sea, for regulating their own maritime affairs;—that hence the laws of Oleron derived their name; and being received in England and France, became known and partially adopted in other nations of Europe. To the copies of the laws appended to the 'Coutumier de Normandie,' and also to those given by Cleirac, in the 'Uz et Coutumes,' an attestation by the seal of the Isle of Oleron is attached, with the date of 1266. This seal is inventoried as having been once in the treasury of the Court of Exchequer. See Palgrave's 'Kalendars and Inventories of the Exchequer,' vol. i., p. 106.

OLI'BANUM. This name, of frequent occurrence in comparatively modern works, does not seem to have been known to ancient commerce or Materia Medica. It appears to have been derived from the Greek λίβανος, or the Arabic *looban*, which is applied, as well as the name *Koondur*, to the substance known in Europe by the name Olibanum. Avicenna describes a resinous substance under the name *Koondur*, to which, in the Latin translations, Olibanum is given as a synonyme, as well as *Thus*, and with this the Arabian author includes a description of the bark, manna, and smoke of Thus, or frankincense; in the same way as we find, in Dioscorides, the description of Libanos, or Thus, followed by that of the other parts we have mentioned, indicating, as is evident indeed from the description, that Avicenna, under *Koondur*, refers to the λίβανος of Dioscorides. Both authors mention an Indian kind of the substance. Mr. Colebrooke ascertained ('Asiatic Res.,' ix. and xi.) that *Koondur* was applied in India to a fragrant resin still used there as incense, and which he ascertained to be the produce of the tree which has been already described under the article Boswellia *thurifera*, in Nat. Hist. Div. The name *Koondur* appears derived from the Sanscrit *Koondooroo*, which is applied to *looban* by the Hindus. ('Fl. Ind.,' ii., p. 384.) The tree is common in the mountains of Central India, as well as in those of the Coromandel coast, together with *B. glabra*, the other species of the genus, and which extends as far north as 30° in the Sewalik or sub-Himalayan range of hills.

Dr. Royle mentions that he has collected off the trunk of this species, in the latter locality, some very clear, pure, and fragrant resin, which burns rapidly away with a bright light, diffusing a pleasant odour. Both species yield this fragrant resin, which is employed as incense in India, and which might be much more extensively collected than at present. From the affinity in vegetation between parts of Arabia, Persia, and India, it is not improbable that the genus Boswellia may extend to Arabia, and there produce the kind known as *Arabian Olibanum*, the tree yielding which has not yet been traced out by botanists. It grows between Berberra and Cape Gardafin, and is exported in Arab vessels. A species of Boswellia would appear to grow in the island of Socotra. See Welstedan, 'Journal of Royal Geographical Society,' vol. v. The conjecture that African olibanum is the produce of *Plöslea-floribunda* (Endlicher) is very improbable, as no sapindaceous plant yields a resinous juice. But with respect to most of the Arabian exports, it is difficult to know whether they are the produce of that country, or have been first obtained by commerce and then re-exported, whence in early times Arabia obtained celebrity for producing so many of the fragrant and aromatic substances which we now know were obtained from Africa and India.

Dr. Royle further states that in Bengal the name *looban* is applied to Benzoin, though in Northern India applicable only to Koondur, the produce of *Boswellia thurifera*, and also that in Persian works, Benzoin is distinguished by the names "hussee-al-jawa" and "hussee looban." ('Illustr. Himal. Bot.,' pp. 177 and 261.)

Olibanum, or true frankincense, is now little used in medicine or surgery. It is burnt as incense, and enters largely into the composition of pastilles.

This substance must not be confounded with common frankincense, the produce of *Abies excelsa*, or common fir.

OLIDIC ACID. [Palmitic Acid.]

OLIVE OIL. [Oils, Manufacture of.]

OLIVILE. ($C_{28}H_{18}O_{10}$?) A colourless crystalline substance found in the resin of the olive. It is soluble in hot water and very soluble in alcohol. Submitted to dry distillation it yields *pyrolivilic acid* ($C_{40}H_{22}O_{10}$). Concentrated hydrochloric or sulphuric acid converts it into a red matter called *olivirutin*.

OLIVIN. [Saliginin.]

OLIVIRUTIN. [Olivile.]

OLYMPIAD. [Æra.]

OLYMPIAN GAMES, the chief of the four great national festivals of the Greeks, were celebrated at Olympia, a sacred spot on the banks of the Alpheus, near Elis, every fifth year. The exact interval at which the Olympia, as the festival was called, recurred was one of forty-nine and fifty lunar months alternately; so that it fell sometimes in the month of Apollonius (July), sometimes in the month of Parthenius (August). (Boeckh ad Pind. 'Olymp.,' iii. 18, p. 138; Müller's 'Dorians,' vol. i., p. 281, trans.) The period between two celebrations was called an Olympiad. The celebration lasted five days.

The origin of this festival is concealed amidst the obscurity of the mythic period of Grecian history. Olympia was a sacred spot and had an oracle of Zeus long before the institution of the games. The Eleans had various traditions which attributed the original foundation of the festival to gods and heroes at a period long before the Trojan War; and among these to the Idæan Heracles, to Pelops, and to Heracles the son of Alcmena. The Eleans further stated, that after the Ætolians had possessed themselves of Elis, their whole territory was consecrated to Zeus; that the games were revived by their king Iphitus, in conjunction with Lycurgus, as a remedy for the disorders of Greece; and that Iphitus obtained the sanction of the Delphic oracle to the institution, and appointed a periodical sacred truce, to enable persons to attend the games from every part of Greece and to return to their homes in safety. This event was recorded on a disc, which was preserved by the Eleans, on which the names of Iphitus and Lycurgus were inscribed. (Plutarch, 'Lycurg.,' 1; Pausan., v. 20, 21.) Other accounts mention Cleosthenes of Pisa as an associate of Iphitus and Lycurgus in the revival of the festival. "All that can be safely inferred from this tradition, which has been embellished with a variety of legends, seems to be, that Sparta concurred with the two states most interested in the plan, and mainly contributed to procure the consent of the other Peloponnesians." (Thirlwall's 'History of Greece,' vol. i., ch. 10.) The date of the revival of the festival by Iphitus is, according to Eratosthenes, 884 B.C.; according to Callimachus, 828 B.C. Mr. Clinton prefers the latter date. ('Fasti Hellenici,' vol. ii., p. 408, note h.) The Olympiads began to be reckoned from the year 776 B.C., in which Coroebus was victor in the foot-race. We have lists of the victors from that year, which always include the victors in the foot-race, and in later times those in the other games. (Pausan., v. 8. 3.)

This, like all the other public festivals, might be attended by all who were of the Hellenic race, though at first probably the northern Greeks and perhaps the Achæans of Peloponnesus were not admitted. Spectators came to Olympia not only from Greece itself, but also from the Grecian colonies in Europe, Asia, and Africa. Among them were solemn deputations sent to represent their respective states. Women however were forbidden to appear at Olympia, or even to cross the Alpheus, during the festival, under pain of death. But at a later period we find the chariots of women mentioned as taking part in the chariot-race, though it is at least doubtful whether the women drove their own chariots. An exception was made to this law of exclusion in favour of the priestess of Demeter, who was permitted to be present at the games, and had a place assigned to her opposite the judges: according to Pausanias (vi. 20) a similar privilege was accorded to virgins, but no other writer refers to such an exemption, and the passage in Pausanias is by some recent authorities believed to be corrupt. The management of the festival was in the hands of the Eleans. Originally indeed Pisa, in which state Olympia lay, seems to have had an equal share in the administration; but in the fiftieth Olympiad the Eleans destroyed Pisa, and from that time they had the whole arrangement of the games. They proclaimed the sacred truce, first in their own territories, and then throughout the rest of Greece. This truce took effect from the time of its proclamation in Elis, and while it lasted the Elean territory was inviolable, any armed invasion of it being esteemed an act of sacrilege. On this privilege the Eleans founded a claim to have their territory always considered sacred, though in fact they themselves did not abstain from war. As the presiding nation, they gave laws for the regulation of the festival, imposed penalties on individuals and states, and had the power of excluding from the games those who resisted their decrees. They actually thus excluded the Lacedæmonians on one occasion and the Athenians on another.

The Eleans appointed the judges of the contests, who were called Hellanodicæ. (Paus., v. 9. 4, 5.) They were instructed in the duties of their office for a period of ten months before the festival by Elean officers, called Nomophylaces (Paus., vi. 24. 3): they were sworn to act impartially, and an appeal might be made from their decision to the Elean senate. (Paus., vi. 24. 3.) Their number varied at different periods: in the 106th Olympiad it was fixed at ten, which was the number ever afterwards. The judges had under them officers, called ἀλύται (*alytæ*), whose business was to keep order. These officers were called *μαστιγόφοροι* (*mastigophori*) in the other Grecian games.

The Olympian festival consisted of religious ceremonies, athletic contests, and races. The chief deity who presided over it was the Olympian Zeus, whose temple at Olympia, containing the ivory and gold statue of the god by Phidias, was one of the most magnificent works of art in Greece. (Paus., v.) The worship of Apollo was associated with that of Zeus (Muller's 'Dorians,' vol. i., p. 279–281, trans.); and the early traditions connect Heracles with the festival. (Ibid., p. 453.) This is another proof of the Dorian origin of the games, for Apollo and Heracles were two of the principal deities of the Doric race. There were altars at Olympia to other gods, which were said to have been erected by Heracles, and at which the victors sacrificed. The most magnificent sacrifices and presents were offered to Zeus Olympius by the competitors and by the different states of Greece.

The games consisted of horse and foot races, leaping, throwing, wrestling, and boxing, and combinations of these exercises. 1. The earliest of these games was the *foot-race* (*δρόμος*), which was the only one revived by Iphitus. The space run was the length of the stadium in which the games were held, namely, about 600 English feet. In the 14th Olympiad (724 B.C.) the *δίαυλος* was added, in which the stadium was traversed twice. The *δόλιχος*, which consisted of several lengths of the stadium (seven, twelve, or twenty-four, according to different authorities), was added in the 15th Olympiad (B.C. 720). A race in which the runners wore armour (*ὁπλιτῶν δρόμος*) was established in the 65th Olympiad, but soon after abolished. 2. *Wrestling* (*πάλη*) was introduced in the 18th Olympiad (B.C. 708). The wrestlers were matched in pairs by lot; when there was an odd number, the person who was left by the lot without an antagonist wrestled last of all with him who had conquered the others. He was called *ἔφεδρος*. The athlete who gave his antagonist three throws gained the victory. There was another kind of wrestling (*ἀνακλινοπάλη*), in which, if the combatant who fell could drag down his antagonist with him, the struggle was continued on the ground, and the one who succeeded in getting uppermost and holding the other down gained the victory. 3. In the same year was introduced the *pentathlon* (*πένταθλον*), or, as the Romans called it, *quinquertium*, which consisted of the five exercises enumerated in the following verse, which is ascribed to Simonides:—

> *Ἅλμα, ποδωκείην, δίσκον, ἄκοντα, πάλην,*

that is, "leaping, running, throwing the discus [DISCUS], throwing the javelin, wrestling." Others give a different enumeration of the exercises of the pentathlon. In leaping, they carried weights in their hands or on their shoulders: the object was to leap the greatest distance, without regard to height. In throwing, neither the discus nor the javelin was aimed at a mark, but he who threw farthest was the victor. In order to gain a victory in the pentathlon, it was necessary to conquer in each of its five parts. 4. *Boxing* (*πυγμή*) was introduced in the 23rd Olympiad (B.C. 688). The boxers had their hands and arms covered with thongs of leather, called *cestus*, which served both to defend them and to annoy their antagonists. Virgil ('Æn.,' v. 405) describes the cestus as armed with lead and iron; but this is not known to have been the case among the Greeks. 5. The *pancratium* (*παγκράτιον*) consisted of boxing and wrestling combined. In this exercise and in the cestus the vanquished combatant acknowledged his defeat by some sign; and this is supposed to be the reason why Spartans were forbidden by the laws of Lycurgus to practise them, as it would have been esteemed a disgrace to his country that a Spartan should confess himself defeated. In these games the combatants fought naked. (Thuc., i. 6.)

The horse-races were of two kinds. 1. The *Chariot-race*, generally with four-horsed chariots (*ἵππων τελείων δρόμος*), was introduced in the 25th Olympiad (B.C. 680). The course (*ἱπποδρόμος*) had two goals in the middle, at the distance probably of two stadia from each other. The chariots started from one of these goals, turned round the other, and returned along the other side of the hippodrome. This circuit was made twelve times. The art of the charioteer consisted in turning as close as possible to these goals, but without running against them or the other chariots. The places at the starting-post were assigned to the chariots by lot. There was another sort of race between chariots with two horses (*δύωρις* or *σύνωρις*). A race between chariots drawn by mules (*ἀπηνή*) was introduced in the 70th Olympiad, and abolished in the 84th. 2. There were two sorts of *races on horseback*, namely, the *κέλης*, in which each competitor rode one horse throughout the course, and the *καλπή*, in which, as the horse approached the goal, the rider leaped from his back, and keeping hold of the bridle, finished the course on foot: in this last only mares were permitted to run.

In the 37th Olympiad (B.C. 632) racing on foot and wrestling between boys was introduced. There were also contests in poetry and music at the Olympian festival.

All persons were admitted to contend in the Olympic games who could prove that they were freemen, that they were of genuine Hellenic blood, and that their characters were free from infamy and immorality. So great was the importance attached to the second of these particulars, that the kings of Macedon were obliged to make out their Hellenic descent before they were allowed to contend. The equestrian contests were necessarily confined to the wealthy, who displayed in them great magnificence; but the athletic exercises were open to the poorest citizens. An example of this is mentioned by Pausanias (vi. 10. 1). In the equestrian games moreover there was no occasion for the owner of the chariot or horse to appear in person. Thus Alcibiades on one occasion sent seven chariots to the Olympic games, three of which obtained prizes. The combatants underwent a long and laborious training, the nature of which varied with the game in which they intended to engage. Ten months before the festival they were obliged to appear at Elis to enter their names as competitors, stating the prize for which they meant to contend. This interval of ten months was spent in preparatory exercises; and for a part of it, the last thirty days at least, they were thus engaged in the gymnasium at Elis.

When the festival arrived, their names were proclaimed in the stadium, and after proving that they were not disqualified from taking part in the games they were led to the altar of Zeus the guardian of oaths (Ζεὺς ὅρκιος), where they swore that they had gone through all the preparatory exercises required by the laws, and that they would not be guilty of any fraud, nor of any attempt to interfere with the fair course of the games. Any one detected in bribing his adversary to yield him the victory was heavily fined. After they had taken the oath, their relations and countrymen accompanied them into the stadium, exhorting them to acquit themselves nobly.

The prizes in the Olympian games were at first of some intrinsic value, like those given in the games described by Homer. But after the 7th Olympiad, the only prize given was a garland of wild olive, cut from a tree in the sacred grove at Olympia, which was said to have been brought by Heracles from the land of the Hyperboreans. Palm leaves were at the same time placed in the hands of the victors, and their names, together with the game in which they had conquered, were proclaimed by a herald. A victory at Olympia, besides being the highest honour which a Greek could obtain, conferred so much honour on the state to which he belonged, that successful candidates were frequently solicited to allow themselves to be proclaimed citizens of states to which they did not belong. Fresh honours awaited the victor on his return home. He entered his native city in triumph, through a breach made in the wall for his reception; banquets were given to him by his friends, at which odes were sung in honour of his victory; and his statue was often erected, at his own expense or that of his fellow-citizens, in the Altis, as the ground at Olympia which was consecrated to the games was called. Three instances are on record in which altars were built and sacrifices offered to conquerors in the Olympic games.

During the celebration of these games, Olympia was a centre for the commerce of all Greece, for the free interchange of opinions, and for the publication of knowledge. The concourse of people from all Greece afforded a fit audience for literary productions, and gave motive for the composition of works worthy to be laid before them. Poetry and statuary received an impulse from the demand made upon them to aid in perpetuating the victor's fame. [Pindar, in Biog. Div.] The influence of the games was thus extended through every part of Greece. Whether the effect of the exercises themselves on the national character was good or evil, is a doubtful question. The exercises of the body, on which these games conferred the greatest honour, were condemned by some philosophers as tending to unfit men for the active duties of a citizen (Arist., 'Pol.,' vii. 14, 18; Athen., x., 413); while they were regarded by others as a most necessary part of a manly education, and as the chief cause of the bodily vigour and mental energy which marked the character of the Hellenic race.

The Olympian games continued to be celebrated with great splendour at Olympia under the Roman emperors; but at length fell into disrepute, and were formally abolished by Theodosius in A.D. 394. The above description of the Olympian games will serve also for the most part for the other three great festivals of Greece. The chief points of difference between them will be seen by referring to the articles Isthmian Games, Nemean Games, and Pythian Games. Several of the Greek states in course of time established festivals in imitation of the Olympian games, which they likewise called Olympia; but their reputation was for the most part local.

(Pausanias, v. vi., &c.; West's Pindar, *Preliminary Dissertation;* Wachsmuth's *Hellenische Alterthumskunde*, Th. i.; Krause, *Olympia, oder Darstellung der grossen Olympischen Spiele;* Thirlwall's and Grote's *History of Greece.*)

OMBROMETER. [Rain-Gauge.]

OMEN, a sign or prognostication of future events, supposed to be an intimation from a superior power. According to Varro ('De Ling. Lat.,' lib. v. c. 7), the word is derived from the language of a person speaking: "Omen, quod ex ore primum elatum est, *omen* dictum;" which was also the opinion of Cicero ('De Divin.,' i., c., 45), who says, "Neque solum Deorum voces Pythagoræi observitaverunt, sed etiam hominum, quæ vocant *omina*" (the Pythagoreans attended to the words not only of gods but also of men, which they called omens). The term afterwards comprehended all signs of future events.

In all probability there is no nation that has not at some time entertained a belief in omens. We find traces of it in the Scriptures. Among the Greeks and Romans it was general. The Persians, the Arabians, the Scandinavians, the Germans, the Icelanders, the ancient Britons, were all imbued with this superstition; as were also the early Christians.

Many curious instances of Roman superstition with reference to omens are enumerated in Pliny (xxxviii. 2). The unlucky omens which preceded the battle of Cannæ are enumerated by Silius Italicus, lib. viii., v. 626, &c.; see also Lucan i., v. 522, &c. Pausanias (iv. 13) enumerates the omens which announced the fate of the Messenians in their struggle with the Lacedæmonians. Suetonius ('Jul.,' § 59) says that Cæsar, in landing at Adrumetum in Africa with his army, happened to fall on his face, which was reckoned a bad omen; but, with great presence of mind, he laid hold of the ground with his right hand, and kissing it as if he had fallen on purpose, he exclaimed, "Teneo te, Africa" (I take possession of thee, O Africa). A similar story is told of William the Conqueror, on landing at Pevensey.

Omens have been frequently spoken of with contempt by men of talent. Homer makes Hector say—

> "Without a sign his sword the brave man draws,
> And asks no omen but his country's cause."

Wythers, in his 'Abuses stript and whipt,' and Dryden and Lee in his 'Œdipus,' act iv., sc. 1, satirise this superstition. Butler frequently alludes to omens in his 'Hudibras;' and by no writer have they been more successfully ridiculed than by Gay in his fable of the 'Farmer's Wife and the Raven.'

A superstitious regard to omens in our own country formerly made a considerable addition to the stock of human misery. Generally speaking, we now look back with indifference on the trivial and ridiculous accidents which alternately afforded matter of joy or sorrow to our ancestors. Nevertheless, in many country places, a superstitious regard to omens still exists.

OMNIBUS. [Stage Carriage.]

OMNIUM, a term used in the Stock Exchange, to express the value, taken as an average, of the different stocks in which a loan is usually funded. Thus, a loan having been contracted for on a certain day, an average is made of the stocks in which such loan is contracted, at the price which they bore on that day, and the fund thus formed as an average of the whole is called Omnium. (M'Culloch's *Dictionary of Commerce.*)

ONION. The species from which the varieties of the common onion have been derived is the *Allium Cepa*. Its uses are almost universally known, and its cultivation is practised in most countries. It was used and liked in Egypt; and the Israelites, under Moses, murmured that they could no more procure it. (Numb., xi. 5.) In Great Britain it has been naturalised from an early date, but is not supposed to be indigenous. The range of latitude within which it may be grown extends from the tropics almost to the coldest verge of the temperate zone. Its leaves and roots are of an annual nature, inasmuch as they die in the course of a single summer, after perfecting a bulb; the latter however is biennial, and capable of putting forth fresh roots and leaves in the following season, and of acquiring an increase in its size.

Onions will succeed in any good rich soil, provided it be neither too wet and adhesive, nor, on the other hand, too dry and light. They may even be grown successively on the same spot for a number of years, contrary to what happens with the majority of crops. Abundance of well-prepared manure should be thoroughly incorporated in digging the soil. The dung of pigeons and poultry is used with advantage; and some, particularly the French gardeners, prefer sheep-dung.

The time of sowing the general crop is from the middle of February to the middle of April, according to the state of the ground and of the weather; but early sowing is best. The seeds may be sown broadcast or in very shallow drills: the latter mode admits of the ground being more easily stirred on the surface and kept clean. In either case the seeds should be covered as lightly as possible.

When the leaves indicate, by the general yellowness of their points, that their office has been performed, the necks should be bent, and the bulbs pulled up soon after, and spread so that their fibres and stems may dry and wither in the sun. They may then be stored up in any dry airy situation.

Very large onions may be obtained by sowing thickly in April on poor soil, so that the produce in the first summer may be of small size. The crop is then taken up as above directed, and the smallest and firmest are selected for planting in rich and well-prepared soil in the following spring.

For a supply of young onions in spring, the sowing should be made in August. Onions are sometimes attacked by a grub at the root. Trenching the soil to a good depth, soot, charcoal-dust, and lime-water, have severally been successfully applied as remedies.

The following are the principal varieties:

Early Silver-skinned—valuable only on account of its earliness.

Silver-skinned—moderately large, flat, shining, white, mild.

Portugal—large, oblate, imported largely from the country of which it bears the name, but only adapted for a supply during the early part of winter; quality rather mild.

Tripoli—the largest of all the varieties: oval, or somewhat flattened, light red, mild, but does not keep long.

Spanish, or *Reading*—large, flat, white, mild; resembles the Portugal onion, but is better adapted for cultivation in this climate.

Strasburg—large, flat or globular, light red, tinged with green, strong-flavoured, and keeps well.

Deptford and *Globe*—are sub-varieties of the preceding, of milder quality, and yield generally good crops.

James's Keeping—large, pyriform, brownish-red; keeps remarkably well; flavour strong.

Blood-red—middle-sized, flat, deep red; keeps well, but of the strongest flavour, on which account it is medicinally preferred to the other varieties.

Yellow or *Straw-coloured* (*Ognon paille ou jaune* of the French)—small, globular, firm, valuable for pickling.

Two-bladed—small, roundish, green, with little foliage.

There are at least twenty varieties of the onion, of which the silver-skinned, two-bladed, and yellow are chiefly grown for pickling. The Portugal and Spanish can only be produced in England by means of transplanting, and growing for two summers. In Portugal it is sown in November and transplanted in April or May. The *Potato* or *Underground Onion* forms numerous bulbs below the surface, which attain maturity early in the summer. The *Tree* or *Bulb-bearing Onion* bears instead of flowers, small bulbs, which, being planted in spring, produce ground onions of good size, and very high flavoured.

ONOMATOPE'IA (*ὀνοματοποιΐα, ὀνοματοποίησις*), which literally means "the making of words," is the name given to those words which are formed, or supposed to be formed, by an imitation of natural sounds. Thus the words "to neigh," "to murmur," "to bleat," "to creak," and many others, are supposed to be merely imitations of natural sounds; but the number of such words has been greatly exaggerated by some grammarians. Aristophanes imitates the croaking of the frogs by *Βρεκεκεκὲξ κοὰξ κοάξ* ('Frogs,' l. 209), and Ennius the sound of the trumpet by the word *taratantara*. (Servius on 'Æn.,' ix. 503.)

ONONETIN. [ONONIN.]

ONONIN ($C_{62}H_{34}O_{37}$). A colourless crystalline, inodorous and tasteless body, extracted from the root of the *Ononis spinosa*. It is insoluble in water and ether, soluble in alcohol, and neutral in its reactions. Treated with boiling caustic potash it is transformed into *onospin* and formic acid:—

$$\underbrace{C_{62}H_{34}O_{37}}_{\text{Ononin.}} + 2HO = \underbrace{C_{60}H_{34}O_{35}}_{\text{Onospin.}} + \underbrace{C_2H_2O_4}_{\text{Formic acid.}}$$

By the action of dilute acids ononin yields *ononetin* ($C_{46}H_{22}O_{13}$?), a colourless crystalline and neutral body insoluble in water. It dissolves in ammonia, and the solution when exposed to the air becomes of a beautiful bright green colour.

ONOSPIN. [ONONIN.]

OPACITY is a condition of bodies by which they are incapable of transmitting light through them. It seems to depend upon the nature or disposition of the particles of bodies, but its precise cause is, at present, far from being understood. According to Newton, opacity may arise from the unequal densities of the particles of certain substances, in consequence of which the rays of light on entering those substances suffer such refractions and reflections as compel them there to remain, and cause them to be finally absorbed; while, in bodies of a homogeneous nature, as glass, diamond, &c., the light experiences so much less of these irregular actions that, except when the thickness of the medium is very great, it is enabled to pass quite through them.

The entire absorption of all the light which enters a substance, merely by the multiplied refractions or reflections which it undergoes within the mass, is difficult to conceive; and the advocates of the undulatory theory ascribe opacity to the unfitness of the pores, or intervals between the molecules of a body, for permitting the vibrations of the particles of ether) without disturbing the molecules, which thus appropriate to themselves the *vis viva* which would otherwise have belonged to the transmitted ethereal vibrations. The same persons consider transparency to consist in such a disposition of the molecules of a body that the incident waves of ether can be propagated with a certain degree of freedom through the mass: some impediment to the propagation of the waves may exist in the most transparent substances; and hence when such substances have more than a certain thickness, the waves cease to be transmitted through them. [TRANSPARENCY; ABSORPTION OF LIGHT.]

OP'ERA (Ital., *work*), a regular drama set to music, always accompanied by scenic representation, frequently by machinery, and sometimes by dancing. It appears (according to Doni) to have originated at Florence towards the end of the 16th century. The true opera, as found on all the Italian stages, whether in Italy or elsewhere, and as performed in the French language at the Académie Imperiale, admits no speaking; all is recitation or air, &c.; while what is called opera in the national theatres of Germany and England, as well as the French *opéra comique*, is of a mixed kind—partly spoken, partly sung. In Italy the opera is divided into four kinds,—namely, the *sacred*, the *serious*, the *semi-serious*, and the *buffa* or *comic*. In France the division is into the *grand'opéra* and *opéra comique*. In Germany the divisions are more numerous, embracing the *grand opera*, the *serious*, the *tragic*, the *heroic*, the *romantic*, the *allegorical*, the *military melodrama*, the *comic*, and others.

The constituents of an opera, says Rousseau, are the poem, the music, and the decorations. The poetry addresses itself to the mind, the music to the ear, the painting to the eye; and it is the duty of the three to unite their powers, in order to move and make an impression on the heart. The truth is, that the poetry of an opera has long ceased to be considered otherwise than as a vehicle for music, and, but for the scenery and decorations, the saying of the Abbé Arnaud, that *the Italian opera is a concert, of which the drama is the pretext*, would be applicable to nine in ten of all productions of the kind that have appeared during the last seventy or eighty years.

The moment that the opera appeared out of its native country, and especially when it reached the British shores, it was attacked by a host of critics and wits. Addison and Swift were among the first to level the shafts of ridicule at it, and were followed by Pope, Young, and many others. Addison lived to retract his opinion; for some of the absurdities which the opera in its infant state presented were soon corrected, though certainly enough remained, and must for ever remain, to sanction the objections of those who tried, or may still judge, the melodrama by the cold stubborn laws of unpoetical probability.

This species of entertainment, though susceptible of much improvement, has not stood quite still while everything else, or nearly everything, has been advancing. That prominent feature, however, in the musical drama, which from the very first proved so obnoxious to ridicule, continues unaltered—the recitative, which provoked the satire of our forefathers, and is yet rather tolerated than approved by the many—if a fault, is, we believe, a fault not imputable to the moderns, but to those whom it has hitherto been thought right to consider as the models of dramatic propriety and poetical taste. This leads to an inquiry concerning the origin of the melodrama—that is, the musical drama, or opera.

That the opera, properly so called, whether Italian or French, is the offspring of the Greek drama,—an opinion that for years past has been gaining ground,—is supported by the most learned and able writers on the subject, and seems likely ere long to be universally adopted. The first that we have met with who has touched on this point is the "philosopher of Malmesbury," Hobbes, who, in a letter to Sir William D'Avenant, says, "There is, besides the grace of style, another cause why the ancient poets chose to write in measured language, which is this: their poems were made at first with intention to have them sung, as well epic as *dramatic* (which custom hath long time been laid aside, but *began to be revived* in part *of late years in Italy*), and could not be made commensurable to the voice or instruments in prose—the ways and motions whereof are so uncertain and undistinguished (like the way and motion of a ship in the sea), as not only to discompose the best composers, but also to disappoint sometimes the most attentive reader, and put him to hunt counter for the sense. It was therefore necessary for poets in those times to compose in verse." This letter is dated Paris, 1650; consequently, written anterior to the establishment of the Académie Royale, or French opera.

Dryden, in the beginning of the preface to his 'Albion and Albanius,' rather hastily calls the opera "a modern invention, though built upon the foundation of the ethnic worship," and conjectures that it was borrowed from the Spanish Moors; but in a postscript to the same he corrects himself in the following rather awkwardly-expressed manner: "Possibly the Italians went not so far as Spain for the invention of their operas; they might have it in their own country, and that by gathering up the shipwrecks of the Athenian and Roman theatres, which we know were adorned with scenes, music, dances, and machines, especially the Grecian." The learned Jesuit, Père Menestrier, in his work 'Des Représentations en Musique,' maintains that the ancient tragedies were chanted. Metastasio, in his 'Estratto della Poetica d'Aristotile,' expresses a most decided opinion that the Greek and Roman dramas, both tragedies and comedies, were sung, and cites in proof of this numerous classical authorities. Pye, in his 'Commentary on the Poetic of Aristotle,' while disputing some of the inferences of Metastasio, is obliged, though unwillingly, to acknowledge that the opera "most probably" is "a lineal and legitimate offspring of the Greek tragedy," and that the vastness of the Roman theatre "turned the necessary means of modulating the voice into a real musical accompaniment;" that is to say, the magnitude of the place rendered chanting or recitative unavoidable.

After collating what has been stated by various authors as to the date of its origin, we are persuaded that no regular opera was produced and publicly performed till Ottavia Rinuccini wrote and Jacopo Peri composed the drama of 'Euridice' for the nuptials of Henri IV. of France and Mary of Medicis. This was represented in a very splendid manner at Florence, in 1600, and there published in the same year. Dr. Berni tells us ('Hist.' iv. 25) that he was never able to find more than one copy of Peri's 'Euridice,' which was in the library of the Marchese Rinuccini, a descendant of the poet. Having the good fortune to possess this very rare work, which is now before us, we can corroborate what the musical historian has said of it, that it is printed in score and barred, two very uncommon circumstances at the time of its publication; that the recitative seems to have been not only the model of subsequent composers of early Italian operas, but of the French operas of Lulli; that figures are often placed over the base to indicate the harmony; that the time changes as frequently as in the old French serious operas; and though the word *aria* occurs, it is difficult to distinguish air from recitative by any superiority of melody, except in the choruses. There is no overture to this, but a musical prologue of seven stanzas instead, sung in the character of Tragedy. Peri, in an address to his *readers* (*à lettori*), gives an account of his orchestra, which was placed behind the scenes, and consisted of a harpsichord, a large guitar, a *lira grande* (that is, a *viol da Gamba*, according to Burney), and an arch-lute.

The Bolognese dispute with the Florentines the honour of having first produced a musical drama, but it appears that the 'Euridice' was performed in their city the year after it had been produced at Florence. The opera was introduced at Venice in 1637, at Naples in 1646, and at Rome in 1671.

The Italian Opera made its way to London by slow and cautious steps. The sudden introduction on the public stage of a foreign language, and that language delivered in recitative, would have put the tolerating spirit of our countrymen to a trial far too severe to be prudent; the event, therefore, which was anxiously wished for by the higher orders, to whom novelty is everything, and by those who had acquired a new taste in their travels, was gradually brought about. In July, 1703, Italian *intermezzi*, or "interludes and musical entertainments of singing and dancing," were performed at York Buildings. Two years after, 'Arsinoe,' translated from the Italian, the dialogue and narrative parts in recitative, and the singers all English, was produced at Drury Lane; the pit and boxes were allotted to subscribers. "Before and after the opera, dancing and singing, by Signora Margarita de l'Epine." In 1706, 'Camilla,' also a translation, was performed by the same persons in a similar manner. The next year witnessed a further and still bolder advance towards the final introduction of the exotic melodrama; 'Thomyris, Queen of Scythia,' was brought out at the same theatre, in which Urbani, a castrato, and two foreign women sang their parts in Italian, the other performers singing theirs in English. At length, in 1710 'Almahide,' written wholly in Italian, and performed exclusively by foreign singers, was presented to the public at the Queen's Theatre in the Haymarket. Thus the Italian opera gained a settlement in this country; and in spite of some opposition and much ridicule by which it was at first attacked, soon became firmly fixed, and now seems to be as necessary, as a source of amusement to the metropolis of this kingdom, as any other favourite and long-established entertainment.

The Italian opera was brought into France in 1646, by the Cardinal Mazarin, and continued for some years to be performed at the Louvre; but the establishment of the Académie Royale des Musique, in 1670, superseded it, and except in 1772, when a troop of Italians represented Pergolesi's 'Serva Padrona' as an *intermezzo*, between the acts of Lulli's 'Acis et Galatée,' it never again was heard at Paris till introduced there early in the present century.

The grand French opera is the legitimate melodrama, being wholly musical, and was founded by Louis XIV. In 1669 that monarch granted letters-patent to the Sieur Perrin for the establishment of an 'Académie des Opéra en Langue Francaise,' who, taking as his partner the Sieur Cambert as composer, commenced his undertaking at the Théâtre de l'Hôtel de Guenégaud, in 1671, where he produced 'Pomone,' the poetry by himself, and set to music by his colleague. This is a pastoral drama, opening with a musical prologue of about thirty lines, in which the author has contrived to stuff a greater quantity of nauseous flattery of the *Grand Monarque* than perhaps was ever compressed into so small a compass. In 1672 the privilege was transferred to Lulli, who, with the assistance of Quinault, a lyric poet of very superior genius, conducted the Académie in a most able and successful manner till his death. [LULLI, in BIOG. DIV.] The *opéra comique* had its birth in France in 1750, in imitation of the Italian *opera buffa*. This, however, is of the mixed kind, the dialogue being spoken.

The genuine Italian opera has long flourished in Germany. On the birth of an archduchess in 1724, an opera was exhibited at Vienna with uncommon magnificence. The opera, entitled 'Eurysteus,' was written by Apostolo Zeno, and composed by Caldara. That imperial poet-laureate was succeeded in office by Metastasio, who wrote many of his admirable lyric dramas for the Italian theatre at Vienna, which were set by the great masters of the day. His 'Clemenza di Tito,' as composed by Mozart, will for ever be considered, by all true judges of dramatic poetry and music, as the most beautiful and finished example of the melodrama that human genius ever produced. For the different German courts some of the finest operas have been composed, but we can here only refer to the names of their authors, GLÜCK, GRAUN, HANDEL, HASSE, MOZART, ROSSINI, SPOHR, WEBER, WINTER, &c., in the BIOG. DIV.

What is called English opera, is with two or three exceptions, of the mixed kind. The first that we have any account of that can be relied on is Shadwell's 'Psyche,' composed by Matthew Lock, and brought out in 1673. Two years after, Dryden wrote his 'Albion and Albanius,' an opera, set by a Frenchman, Louis Grabut, whom, to please the antinational king, Charles II., Dryden, in a preface to the work, praises in high though most undeserved terms, at the expense of his countrymen. But when that great poet wrote his 'King Arthur,' he was fain to apply to Purcell for assistance, whose music has saved it from the oblivion to which it would otherwise be condemned. The poet, in an epistle-dedicatory to this, takes an opportunity of retracting his opinion of English composers. He says that music had then "arrived at a greater perfection in England than ever formerly; especially passing through the artful hands of Mr. Purcell, who has composed it with so great a genius, that he has nothing to fear but an ignorant ill-judging audience," Addison's 'Rosamond' was, it is to be supposed, a real opera, the dialogue in recitative. This was represented in 1707, but failed, as Hawkins tells us, owing to the poverty of the music by one Clayton. 'The Beggar's Opera' is so well known that it need only be named. The music is a good selection of the airs most popular at the time, arranged by the celebrated Dr. Pepusch 'Artaxerxes,' by Dr. Arne, is the only opera, strictly so called, that keeps its place on the stage. This is nearly a translation of Metastasio's 'Artaserse,' by the composer himself, and though at the time severely criticised, is far superior to most of the musical dramas that have since been written. The music is rich in beautiful melody, and if other attempts at an English recitative opera had proved equal to this, the melodrama might now have been firmly rooted in British ground. Arne composed many other charming musical pieces; his 'Love in a Village' will never be superannuated; and in truth, if the dramatic music of some of our countrymen who charmed the public ear during the latter half of the last century could be heard without prejudice, and without that yearning after what is foreign and new which characterises "the fashionable world," and others who yield to its influence, it would be admitted that in original expressive melody we are inferior to no nation in Europe, startling as the proposition may be to those who have not impartially and duly considered the subject. [ARNE; ARNOLD; BISHOP; DIBDIN; JACKSON; LINLEY; SHIELD; STORACE; in BIOG. DIV.]

OPERATION. This article is to be considered as a continuation of ALGEBRA, and as a development of the views of the nature of algebra there laid down. It cannot be read entire, except by students who have some acquaintance with the Differential Calculus, &c.

The great considerations on which the mathematics are founded have always, until lately, been stated as those of number and space; so that arithmetic and geometry have been called the wings of this branch of exact science. This similitude, suggested by the twofold character of its objects of comparison, may be carried a step further; for as wings will not enable a bird to fly without nerves and sinews, so the mere consideration of space and number will never make a mathematician, without an organised method of using the ideas of both. We have already [MATHEMATICS] suggested that the science of operation must be a constituent part of mathematics; but it has always been so mixed up with the sciences bearing names derived from number and measure, that until lately it has had neither separate name nor existence; and even now, what has been done in it is only the mere beginning of a system.

The use of symbols of operation not standing for magnitudes but for directions how to proceed with magnitudes, began with Leibnitz and Newton, before whose time all algebraical characters denoted simple numbers. The progress of the Differential Calculus forced the attention of mathematicians upon modes of denoting, not results of processes, but ways of proceeding. The generalisations arising out of the organisation which notation gave to processes led to the use of indefinite and arbitrary symbols of operation. [FUNCTION.] Finally, it was observed that the symbols of operation employed in many general theorems would give simple and well-known relations if their meaning as symbols of operation were forgotten, and they were considered as symbols of quantity. For example, if $\Delta\phi(x)$ be $\phi(x+1)-\phi x$, Δ being a symbol, not of a quantity multiplying ϕx, but of an operation to be performed upon ϕx; and if $\mathrm{D}\phi x$, $\mathrm{D}^2\phi x$, &c. denote the successive differential coefficients of ϕx, Taylor's theorem gives

$$\Delta\phi x = \mathrm{D}\phi x + \frac{1}{2}\mathrm{D}^2\phi x + \frac{1}{2\,.\,3}\mathrm{D}^3\phi x + \ldots .$$

If Δ and D had stood for quantities (which they do not), the preceding equation might have been divided by ϕx, and the result would have been

$$\Delta = \mathrm{D} + \frac{1}{2}\mathrm{D}^2 + \frac{1}{2\,.\,3}\mathrm{D}^3 + \ldots . = \epsilon^{\mathrm{D}} - 1 \ldots . \text{(A)}$$

If such a result had been obtained by those mathematicians who first ventured on the use of a negative quantity, they would doubtless have given to operations a sort of existence as quantities, and would have felt no repugnance to say that the direction to change ϕx into $\phi(x+1)-\phi x$ was equal to ϵ raised to the power of a direction to differentiate ϕx, diminished by a unit. This might have beat their negative quantity (or arithmetical quantity less than nothing) in the complication of its absurdities, but not in absolute impossibility. Let two persons be required, the one to take four yards out of three, and the other to subtract a unit from—not the differential coefficient of ϕx, but—the direction to take the differential coefficient of ϕx, and it could hardly be said that the first had a more hopeless task than the second.

The modern mathematicians, with Lagrange at their head, had had too much experience of the nature of extensions to hazard any assumption upon the properties of symbols of operation, when separated from the quantity to be operated upon. The first step made was the observation that certain theorems involving symbols of operation might be easily remembered by the resemblance of the formulæ to well-known expressions; in fact, by the coincidence of those formulæ with the expressions, on the supposition that the symbols of operation are changed in meaning, and become symbols of quantity. And if it be said that these mathematicians were saved from introducing a difficulty analogous to that of negative quantities by the want of resemblances already existing in common modes of speaking and common views of arithmetic, it may be answered that such was not the case, but that it would have been easy, and was not without precedent, to consider arithmetic itself as a science of operations upon one single magnitude, the unit. If we always express the unit by I, we may, if we please, consider 2 not as $\mathrm{I}+\mathrm{I}$, but as the direction to perform upon I the operation in $\mathrm{I}+\mathrm{I}$; so that 2 being merely a direction what to do, $2\mathrm{I}$

may represent the result of so doing: similarly 3 may be the direction to proceed as in I + I + I, and 3 I its result. And 3 × 2 would be a direction to perform 3 upon the result of 2, or to take 2 I + 2 I + 2 I, or (I + I) + (I + I) + (I + I), or 6 I. If then we say 3 × (2 I) = 6 I, we have an equation between magnitudes; but if we throw away I, as we just now did ϕx, we have 3 × 2 = 6, an expression of equivalence of operations. Now it might very reasonably have been asked whether *these* operations must be the only ones which will admit of being treated by themselves and viewed independently of the subjects of operation; and a direct assumption of such modes of notation as that marked (A), even when Δ and D were considered independently, though it might not have been fully explicable, would have appeared to be nothing but a natural extension of views which had already been taken to a limited extent.

The process however which was actually followed was this: forms similar to (A) having been observed, in which, whatever might be thought of them as they stood, were found ready means of returning to well-known truths, it was natural to ask whether an application of algebra to the form (A), producing of course a transformation of both sides, would lead to a result from which, by the same method of returning, another known truth might be produced. For example, assume that D and Δ are to be treated as quantities: then $\Delta = \epsilon^{\mathrm{D}} - 1$ gives $1 + \Delta = \epsilon^{\mathrm{D}}$, log. $(1 + \Delta) = \mathrm{D}$, or

$$\mathrm{D} = \Delta - \frac{1}{2}\Delta^2 + \frac{1}{3}\Delta^3 - \ldots .$$

Now restore ϕx to every term, and let D and Δ reassume their operative meanings, so that $\mathrm{D}\phi x$ is the differential coefficient, and $\Delta\phi x$, $\Delta^2\phi x$, &c., are the successive DIFFERENCES of ϕx, x being changed into $x+1$ at each step. We have then

$$\mathrm{D}\,\phi x = \Delta\,\phi x - \frac{1}{2}\Delta^2\phi x + \frac{1}{3}\,\Delta^3\,\phi x - \ldots$$

a theorem which must be true if the preceding method be legitimate. This theorem is found to be true by other and certain modes of demonstration: consequently the legitimacy of the preceding method has some presumption in its favour, arising from its leading to an otherwise known truth.

In this way many theorems were investigated, upon the following plan of proceeding:—1. Throw away symbols of quantity from a known theorem, and proceed in any manner which may appear eligible with the symbols of operation, treating them as if they were quantities. 2. When a result has been obtained, restore the symbols of quantity to their old places, and those of operation to their old meanings. 3. The result as thus viewed has all the presumption in its favour which arises from its being the legitimate consequence of a method which, whether accurate or not, has never been found to lead to anything but what could otherwise be satisfactorily shown to be true. And though Lagrange himself, Arbogast, the English translators of Lacroix, Brinkley, &c., may have used language in reference to this method which would seem to imply that they considered it as one of demonstration, yet it is obvious, from the care taken by them to have abundant external verification in every case, that their results were considered by themselves as resting on such a presumption as that above noted; though it is also evident that they considered the presumption as amounting to moral certainty, which indeed they were justified in doing.

A student who reads on this subject for the first time will be apt to let his ideas run farther than they should, and to imagine that this treatment of operations may be made universal. For instance, if $\phi x = x^2$ and $\psi x = x^3$, and if $\phi + \psi$ be taken as representing $x^2 + x^3$, he might suppose that $\phi + \psi$ performed twice, or

$$(x^2+x^3)^2 + (x^2+x^3)^3$$

represented by $(\phi + \psi)^2$, should be the same thing as

$$\phi^2 + 2\phi\psi + \psi^2, \text{ or } (x^2)^2 + 2(x^2)^3 + (x^3)^3.$$

This however will be found not to be the case, and thus it appears that a line is to be drawn, distinguishing operations which may be used independently of quantities from those which may not. Until this line can be properly drawn, nothing like demonstration of the method, when true, can be given; or rather perhaps the converse, that is to say, a method of demonstration of such cases as give truths will draw the line which separates these from the rest. We proceed to give some account of this method of demonstration.

We do not know how far those who used the *separation of the symbols of operation and quantity* (as it was called) had before their minds a view that would have made their method intelligible in a rational point of view, which was all it wanted of mathematical exactness. But, looking only at their modes of expression, we cannot find anything of the kind. Lagrange ('Mém. Acad. Berlin,' 1772) gave only theorems without any mode of deducing them. Arbogast assumes the "séparation des échelles" without remark. Laplace, by the aid of his theory of generating functions, must be held to have strictly demonstrated some isolated classes of the theorems which this method gives. But nothing like a general account of the reason why this separation of the symbols of operation and quantity leads to truth in certain cases and not in others, ever appeared, to our knowledge, before the publication of a memoir by M. Servois in the 5th volume of the 'Annales de Mathématiques' (Lacroix, vol. iii., p. 726). The author exhibits those properties of the separable operations on which the legitimacy of the separation depends; and making a separate species of calculus of functions out of those properties, fully succeeds in demonstrating that differences, differentiations, and multiplications by any factors which are independent of the variables, may be used as if their symbols of operation were common algebraical quantities.

The last step towards the full conception of a *calculus of operations* was virtually made by Dr. Peacock, in his 'Algebra' (first edition, 1830); for though this work does not mention the subject, yet it is the first which lays down the principles on which the theory of separation is neither a resemblance of algebra, nor a calculus of functions founded on algebra, but *an algebra*, or if the reader pleases, algebra itself; so that its conclusions rest upon the same foundation as those of ordinary algebra.

We have [ALGEBRA] pointed out what is meant by symbolical algebra, as distinguished from explained or interpreted algebra. Granting a certain number of fundamental relations, which are to be true, the logical consequences of combining those relations must be true also: thus, if it be universally true that $a+b=b+a$, and that $xy=yx$, it follows, even before $a, b, +, x, xy$, &c., have any meaning assigned, that $(a+b)z=z(a+b)=z(b+a)$. If, as in the article cited, we select all the primary relations on which algebraical transformations depend, and then bear in mind that the truth of all their consequences depends on the truth of those relations only, not on the relations being true for one meaning or another meaning of the symbols, but on the truth only of the relations, come how it may—we shall then see that all formulæ of algebra may be used as expressions of truths, whatever may be the meaning of the symbols employed, provided only that, such meanings being given, the fundamental relations are true. We have already seen that this may be carried the length of extending the meanings of all the symbols of algebra, in such manner that a science is created with definitions wide enough to include among its rational objects not only the negative quantity, but also its square root. This was *extension* only; we shall now show a process which, though it be still extension, is of another character.

In our present inquiry, we need not trouble ourselves to make any particular consideration of the signs + and −. They retain their algebraical meaning, so that whatever A and B may stand for, $+(+\mathrm{A}) = +\mathrm{A}$, $-(+\mathrm{A}) = -\mathrm{A}$, &c.

If we now ask, what are the fundamental symbolical relations of algebra which remain, after those which depend on + and − are taken away, we shall find them to be as follows:—1. The *distributive* character, as it is called, of the operation ab, with respect to + and −, as shown in $a(b+c-e)=ab+ac-ae$. 2. The *commutative* or *convertible* character of the same operation with respect to others of the same kind and itself, as shown in $abc=acb=bca$, &c., and $ab=ba$. 3. The *depressible* character of operations of the species a^m, when performed upon other operations of the same kind, as shown in $a^m a^n = a^{m+n}$, $(a^m)^n = a^{mn}$. These laws of operation being granted, no matter what the nature of the interpretation under which it is found possible to grant them, all that is necessary to the mechanism of algebra will be found to have been granted. It will be remembered that we speak of $1 \div a$ under the symbol a^{-1}.

In arithmetic, as already seen, we may, if we please, consider the symbols 2, 3, &c., as indicative of operations performed upon the unit. Let us extend this notion, and, instead of the unit, make ϕx, any function of a variable x, the subject of operation; this function being always understood, if not expressed. Thus any symbol E has an operative meaning in itself, but when written in an equation stands for the result obtained by performing that operation upon ϕx, which may also be signified by $\mathrm{E}(\phi x)$. Also let $\mathrm{E}+\mathrm{F}$ and $\mathrm{E}-\mathrm{F}$ stand for the algebraical sum and difference of the results of the operations E and F performed upon ϕx. Let us now appropriate E to stand for the simple operation of changing x into $x+h$, or x + any quantity independent of x in value: and to distinguish the different increments, let E_h, E_k, &c., denote the operations of changing x into $x+h$, $x+k$, &c. It is then very easily shown that E possesses the distributive, convertible, and depressible characters essential to its being logically the object of algebraical transformation. Take two functions, ϕx and ψx, either assumed independently or resulting from preceding operations: it follows then that $\mathrm{E}_h(\phi x \pm \psi x)$ is $\phi(x+h) \pm \psi(x+h)$, which is $\mathrm{E}_h\,\phi x \pm \mathrm{E}_h\,\psi x$; or the distributive character is established. Again, consider $\mathrm{E}_h(\mathrm{E}_k\,\phi x)$ and $\mathrm{E}_k(\mathrm{E}_h\,\phi x)$: first, $\mathrm{E}_k\,\phi x$ means $\phi(x+k)$, on which perform E_h, or change x into $x+h$, giving $\phi(x+h+k)$; next, $\mathrm{E}_h\,\phi x$ is $\phi(x+h)$, on which E_k being performed, gives $\phi(x+k+h)$, the same as $\phi(x+h+k)$. Consequently $\mathrm{E}_h\,\mathrm{E}_k\,\phi x = \mathrm{E}_k\,\mathrm{E}_h\,\phi x$, or the convertible character of E is established. Thirdly, consider $\mathrm{E}_h^3\,\mathrm{E}_h^2$, meaning that the operation E_h having been twice performed, E_h is to be three times performed upon the result: we have evidently $\phi(x+5h)$, or $\mathrm{E}_h^5\,\phi x$; and if E_h^3 were to be performed four times running, we should have E_h^{12}. Hence the depressible character of the successive operations is established: and though it be a wide step for the beginner to make, the applicability of all the formulæ of algebra is now proved, subject, as in common algebra, to difficulties of interpretation occurring in results.

A simplification of the preceding notation may be made as follows: if E or E^1 be simply a direction to increase x by unity, and E^0 a direction to let it remain unaltered, it is clear that $\mathrm{EE}.\ \phi x$ must mean $\phi(x+1+1)$, or $\mathrm{E}_2\,\phi x$; so that $\mathrm{E}^2\,\phi x$ and $\mathrm{E}_2\,\phi x$ are the same. Similar reasoning applies to E_h whenever h is a whole number; and shows that it is E^h and nothing else. Similar reasoning also applies to E^{-h} where h is a whole number: for E^{-h} must be so interpreted that E^h performed upon it may give E^{h-h} or E^0; that is, $\mathrm{E}^{-h}\,\phi x$ with x changed h times into $x+1$ must be $\mathrm{E}^0\,\phi x$, or ϕx; or $\mathrm{E}^{-h}\,\phi x$ must be $\phi(x-h)$. In like manner it may easily be shown that *one of the meanings* of $\mathrm{E}^h\,\phi x$, where h is fractional, is $\phi(x+h)$: but, as in common algebra, of which all the conclusions, as shown, here apply, when h is a fraction, E^h may be any one out of operations as many in number as there are units in the denominator of h. To take a very simple case, required $\mathrm{E}^{\frac{h}{2}}\,\phi(x)$, meaning an operation which, twice repeated, gives $\mathrm{E}^h\,\phi x$, or $\phi(x+h)$. This condition is evidently satisfied by $\phi(x+\frac{1}{2}h)$, but it is also satisfied by $-\phi(x+\frac{1}{2}h)$, for if part of the operation consist in change of sign, two repetitions of the operation reproduce the original sign.

It must not be forgotten that, in finding new objects of algebraical reasoning, we have not lost our rights over the old ones; thus any letter may stand for a multiplier or divisor of the universal subject of calculation, ϕx. *But these independent multipliers must not contain x:* for if they did contain x, the convertibility of the multipliers with E would not any longer be practicable. If, for instance, we consider $a\,\mathrm{E}\phi x$, which is $a\,\phi(x+1)$, we find it to be the same as $\mathrm{E}(a\phi x)$, for a, being independent of x, is not affected by E. But if we consider $x\mathrm{E}\phi x$, and $\mathrm{E}(x\phi x)$, we find the first to be $x\phi(x+1)$, and the second to be $(x+1)\,\phi(x+1)$. A wide branch of the calculus of operations exists, in which the convertible character of the operations is not made a postulate. Our limits will not allow us to enter upon it, except to a very small extent, as presently given: but there is one elementary work on the subject, Carmichael, 'Calculus of Operations,' 1855; and there is a good deal on the subject in Boole, 'On the Calculus of Finite Differences,' 1860.

To generalise the preceding, we may suppose $\mathrm{E}^0\phi x$ to mean ϕx as before, and $\mathrm{E}\phi x$ to stand for $\phi(x+a)$, where a may have any value we please independent of x. And it is in our power to abbreviate any collection of operations by using a single symbol to stand for it. Thus Laplace uses $\nabla\,\phi x$ to stand for such a set of operations as

$$\mathrm{A}_0\,\phi(x)+\mathrm{A}_1\,\phi(x+a)+\mathrm{A}_2\,\phi(x+2a)+\ \ldots.$$

which we should denote by

$$\nabla=\mathrm{A}_0+\mathrm{A}_1\,\mathrm{E}+\mathrm{A}_2\,\mathrm{E}^2+\ \ldots.$$

Again, if in common algebra fy were $\mathrm{A}_0+\mathrm{A}_1 y+\ \ldots.,$ we might abbreviate the preceding into $f\mathrm{E}$ instead of ∇.

But it may be said that this, though intelligible as to a simple operation E, its repetitions E^2, E^3, &c., its inverse and repetitions of it E^{-1}, E^{-2}, &c., ceases to have meaning when we come to apply it to other functions of algebra. What, for instance, is $\log.\,(1+\mathrm{E})$? How can the direction to add $\phi(x+a)$ to ϕx have a logarithm? This question arises from the student having carried with him into purely symbolical algebra (in which it is the first requisite to drop all meanings) significations of symbols derived from ordinary arithmetical algebra. Now it is to be remembered that as far as we have yet gone, all the transcendental symbols of algebra, a^{E}, $\log\ \mathrm{E}$, $\sin\ \mathrm{E}$, $\cos\ \mathrm{E}$, &c., have not been mentioned, far less defined; they are not therefore absurd, but only, for the present, unmeaning. The question is, how are we to give them meaning; at our pleasure, or by deduction? Evidently the latter, for we are bound to retain the power of using algebraical transformations as they now exist. Since then a^x in common algebra is equivalent to $1+\log a.\,x+\frac{1}{2}\,(\log\ a.)^2x^2+\ldots\ldots$ we must lay it down that $a^{\mathrm{E}}=1+\log a.\ \mathrm{E}+\ldots.$, or that a^{E} must be viewed, when it means an operation to be performed upon ϕx, as an abridgment of

$$\phi x+\log a.\ \mathrm{E}\phi x+\tfrac{1}{2}\,(\log a.)^2\,\mathrm{E}^2\phi x+\ldots.$$

This is unquestionably the most difficult step of the whole: we shall have occasion further to consider it in the article RELATION, but for the present the following may be sufficient. Since the total operation $\mathrm{A}_0+\mathrm{A}_1\mathrm{E}+\mathrm{A}_2\mathrm{E}^2+\ldots.$ can be easily understood, consisting merely of the successive performance of the operation E, the multiplication of the results by given quantities of common algebra, and the addition of the products; and since all the transcendentals of common algebra can be expanded, in series of the above form, in such manner that the series have all the algebraical properties of the transcendentals they stand for; let us consider the transcendental symbols of operation as abbreviations of the series, supposed to stand for series of operations.

We shall now proceed to some examples. First, let it be required to transform the series $\mathrm{A}_0\phi x+\mathrm{A}_1\,\phi(x+a)+\mathrm{A}_2\phi(x+2a)+\ldots.$ This may be represented by $\mathrm{A}_0+\mathrm{A}_1\,\mathrm{E}+\mathrm{A}_2\mathrm{E}^2+\ \ldots$ performed upon ϕx. Let the latter series in common algebra be $f\mathrm{E}$, then $f\mathrm{E}$, considered as a symbol of operation, stands for the preceding complex operation. Let the transformation be required to be made into a series of terms containing ϕx and its differences: let $\phi(x+a)-\phi x=\Delta\phi x$, then $\mathrm{E}-1$ is Δ, or $\mathrm{E}=1+\Delta$. But $f\mathrm{E}$ or $f\,(1+\Delta)$ is $\mathrm{B}_0+\mathrm{B}_1\Delta+\mathrm{B}_2\Delta^2+\ \ldots.$ where B_0, B_1, &c. are the values of fy and its successive differential coefficients when $y=0$, divided by 1, 1, 1.2, 1.2.3, &c. Consequently the preceding series is the same as $\mathrm{B}_0\phi x+\mathrm{B}_1\Delta\phi x+\mathrm{B}_2\Delta^2\phi x+\ldots.$ For instance, let the series be $\phi x-\phi\,(x+a)+\phi(x+2a)\ldots$ or $(1-\mathrm{E}+\mathrm{E}^2-\ldots.)\,\phi x$ or $(1+\mathrm{E})^{-1}\,\phi x$. Write $1+\Delta$ for E, and we have $(2+\Delta)^{-1}\,\phi x$ or

$$\left(\frac{1}{2}-\frac{1}{4}\,\Delta+\frac{1}{8}\,\Delta^2-\ldots\right)\phi x,\ \text{or}$$

$$\frac{1}{2}\,\phi x-\frac{1}{4}\,\Delta\,\phi x+\frac{1}{8}\,\Delta^2\phi x-\ldots$$

We have chosen this result as one which is very easy to verify. Let ϕx, $\phi\,(x+a)$, &c., be denoted by X_0, X_1, &c., then [DIFFERENCES] we have

$$\phi x=\mathrm{X}_0,\ \Delta\phi x=\mathrm{X}_1-\mathrm{X}_0,\ \Delta^2\phi x=\mathrm{X}_2-2\mathrm{X}_1+\mathrm{X}_0,$$

$$\Delta^3\phi x=\mathrm{X}_3-3\mathrm{X}_2+3\mathrm{X}_1-\mathrm{X}_0,\ \&c.$$

Substitute these in $\frac{1}{2}\ \phi x-\frac{1}{4}\,\Delta\phi x+\ \ldots$, and we have $\frac{1}{2}\ {}_0-\frac{1}{4}$ $(\mathrm{X}_1-\mathrm{X}_0)+\ \ldots.:$ take a few terms, developing the fractiona multiplication, and we shall find the preceding to be identical with

$$\left(\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\ldots\right)\mathrm{X}_0-\left(\frac{1}{4}+\frac{2}{8}+\frac{3}{16}+\ldots\right)\mathrm{X}_1+$$

$$\left(\frac{1}{8}+\frac{3}{16}+\frac{6}{32}+\ldots\right)\mathrm{X}_2-\ \ldots.\ \text{or}$$

$$\frac{1}{2}\left(1-\frac{1}{2}\right)^{-1}\mathrm{X}_0-\frac{1}{4}\left(1-\frac{1}{2}\right)^{-2}\mathrm{X}_1+\frac{1}{8}\left(1-\frac{1}{2}\right)^{-3}\mathrm{X}_2-$$

$$\text{or }\mathrm{X}_0-\mathrm{X}_1+\mathrm{X}_2-\ldots\ \text{or }\phi x-\phi\,(x+a)+\phi\,(x+2a)-\ldots$$

We shall now take an example of interpretation. Required the meaning of Δ^{-1} by means of E? Since $\Delta=\mathrm{E}-1$, we have $\Delta^{-1}=(\mathrm{E}-1)^{-1}=\mathrm{E}^{-1}+\mathrm{E}^{-2}+\mathrm{E}^{-3}+\ldots.$ or

$\Delta^{-1}\,\phi x$ means $\phi\,(x-a)+\phi\,(x-2a)+\ \ldots.$ *ad infinitum.*

This is easily shown to be consistent with the relation $\Delta\Delta^{-1}=1$ or $\Delta\Delta^{-1}\,\phi x=\phi x$, for if the preceding series be called ψx, we have $\Delta\Delta^{-1}\phi x=\Delta\psi x=\psi\,(x+a)-\psi x=(\phi x+\phi(x-a)+\ \ldots.)-(\phi(x-a)+\phi(x-2a)+\ \ldots.)=\phi x$. We have thus obtained and verified one of the infinite number of forms which $\Delta^{-1}\,\phi x$ may represent.

As yet we have nothing which might not have been done with tolerable ease by common methods, nor shall we have done more in proving Taylor's Theorem, but the step which we shall make to follow that proof will be an instance of the deduction of a theorem which is of a more difficult character.

Let $(\phi(x+\theta)-\phi x):\ \theta$ be called D_θ: then the smaller θ becomes, the more nearly is $\mathrm{D}_\theta\phi x$ the differential coefficient of ϕx, or $\phi' x$. Let θ be the nth part of the given quantity a: then the smaller θ is, the greater must n be. We have then

$$\phi(x+\theta)=(1+\theta\mathrm{D}_\theta)\,\phi x,$$

$$\phi\,(x+2\theta)=(1+\theta\mathrm{D}_\theta)^2\,\phi x,\ \text{since}$$

$$\phi\,(x+2\theta)-\phi\,(x+\theta)=\theta\mathrm{D}_\theta\phi\,(x+\theta)\ \text{or}$$

$$\phi\,(x+2\theta)=(1+\theta\mathrm{D}_\theta)\,\phi\,(x+\theta)=(1+\theta\mathrm{D}_\theta)^2\,\phi x.$$

Proceeding in this way we obtain $\phi\,(x+n\theta)$ or $\phi\,(x+a)=(1+\theta\mathrm{D}_\theta)^n\,\phi x$ $=\phi x+n\theta\mathrm{D}_\theta\phi x+n\,\frac{n-1}{2}\,\theta^2\mathrm{D}^2_\theta\phi x+\ \ldots.$ For $n\theta$ write a, and the preceding becomes

$$\phi x+a\mathrm{D}_\theta\phi x+a\,\frac{a-\theta}{2}\,\mathrm{D}^2_\theta\phi x+\ldots.$$

which being always $=\phi\,(x+a)$, has a limit also $=\phi\,(x+a)$. Take that limit by diminishing θ without limit, and we see that $\mathrm{D}_\theta\phi x$, $\mathrm{D}^2_\theta\phi x$, &c., become $\phi' x$, $\phi'' x$, &c., or

$$\phi\,(x+a)=\phi x+\phi' x.\,a+\phi'' x\,\frac{a^2}{2}+\ldots.$$

which is Taylor's Theorem. Suppose we denote the operation of differentiation by D, and $\phi\,(x+a)-\phi x$ by $\Delta\phi x$, we have then

$$1+\Delta=1+a\mathrm{D}+\frac{a^2}{2}\,\mathrm{D}^2+\ \ldots.=\epsilon^{a\mathrm{D}};$$

a particular case of which (when $a=1$) was chosen as our illustration at the beginning of this article. This relation $1+\Delta=\epsilon^{a\mathrm{D}}$ gives us a great power of converting series which contain differences into those containing differentials, and *vice versâ.*

We now propose to interpret D^{-1}. This symbol must satisfy $\mathrm{DD}^{-1}\,\phi x=\phi x$, and $\mathrm{D}^{-1}\,\mathrm{D}\,\phi x=\phi x$, the first of which is satisfied by $\mathrm{D}^{-1}\,\phi x=\int\phi x\,dx+\mathrm{C}$, where C may have any constant value: but the second is only satisfied by $\int\phi x\,dx$, beginning at a value of x which maks $\phi x=0$. We shall however see that we need not enter on this question in reference to the theorem immediately following.

Let it be required to express $\Delta^{-1}\phi x$, or $\phi(x-a)+\phi(x-2a)+\ \ldots$ *ad inf.*, by means of operations of the differential and integral calculus.

Since Δ is $\epsilon^{a\mathrm{D}}-1$, we have to find $(\epsilon^{a\mathrm{D}}-1)^{-1}$ expanded in powers[*] of D. Now common algebraical processes show that $(\epsilon^{t}-1)^{-1}$ can be developed in the series

$$\frac{1}{t}-\frac{1}{2}+\mathrm{B}_1\frac{t}{2}-\mathrm{B}_3\frac{t^3}{2.3.4}+\mathrm{B}_5\frac{t^5}{2.3.4.5.6}-\&c.,$$

where B_1, B_3, B_5, &c., are the Numbers of Bernoulli, of which an ample stock is given in the article cited: thus $\mathrm{B}_1=\frac{1}{6}$, $\mathrm{B}_3=\frac{1}{30}$, &c. Write $a\mathrm{D}$ for t, restoring ϕx, and for $\mathrm{D}\phi x$, &c., write $\phi' x$, &c. but for $\mathrm{D}^{-1}\phi x$ write $\int\phi x dx+\mathrm{C}$. We have then

$$\phi(x-a)+\phi(x-2a)+\phi(x-3a)+\ \ldots\ ad\ infin.$$
$$=\frac{1}{a}\int\phi x dx+\mathrm{C}-\frac{1}{2}\phi x+\frac{\mathrm{B}_1 a}{2}\phi' x-\frac{\mathrm{B}_3 a^3}{2.3.4}\phi''' x+\ldots.$$

The determination of the constant might in many cases be troublesome, but if we only want a finite number of terms of the series, we can avoid it altogether as follows. Let $x-na=y$, and suppose that $\phi(x-a)+\ldots.$ ending with $\phi(x-na)$ is sought. Write y instead of x in the preceding, remembering that $y-a=x-(n+1)a$, &c.: subtract the result thus obtained from the preceding, and we have

$$\phi(x-a)+\phi(x-2a)+\ldots.+\phi(x-na)$$
$$=\frac{1}{a}\int\phi x dx-\frac{1}{a}\int\phi y dy-\frac{1}{2}(\phi x-\phi y)+\frac{\mathrm{B}_1 a}{2}(\phi' x-\phi' y)-\ldots.$$

But $\int\phi x dx-\int\phi x y dy$ is $\int\phi x dx$ taken from y to x, or if $\phi_1 x$ differentiated give ϕx, it is $\phi_1 x-\phi_1 y$. We introduce this process merely to give some idea of the process to the reader who is already master of the result from other sources; and we cannot here explain the reason why one particular form of $\Delta^{-1}\phi x$ is taken.

For further developments of the results of this subject, see the Appendix to the Translation of Lacroix; Herschel's 'Examples of the Calculus of Differences;' Lacroix's large work on the Differential Calculus, vol. iii.; 'Library of Useful Knowledge—Differential Calculus;' a paper by Mr. Murphy in the Phil. Trans. for 1837; and various papers in the numbers of the 'Cambridge Mathematical Journal.' In several of these works further references will be found. Many other references might be given to scattered volumes: but the student will find much collected together in Professor Boole's two recent works on Differential Equations and on Finite Differences. The student may make an attempt at the demonstration of the following theorem a test of his understanding the method which we have explained, and the points of analysis which are most essential as preliminaries. Whatever a may be, the differential coefficient of ϕx is an algebraical equivalent of the following series:

$$\frac{\phi(x+a)-\phi(x-a)}{a}-\frac{\phi(x+2a)-\phi(x-2a)}{2a}$$
$$+\frac{\phi(x+3a)-\phi(x-3a)}{3a}-\ldots.$$

Instead of supposing ϕx, a function of x only, to be the fundamental subject of operations, we might make it $\phi(x, x_{,})$ and suppose E and $\mathrm{E}_{,}$ to represent the operations of changing x into $x+a$ and $x_{,}$ into $x_{,}+a_{,}$. We can only briefly note some of the results of this extension. If D and $\mathrm{D}_{,}$ represent the operations of differentiation with respect to x and to $x_{,}$, we have in

$$\mathrm{E}\mathrm{E}_{,}=\epsilon^{a\mathrm{D}+a_{,}\mathrm{D}_{,}}=1+(a\mathrm{D}+a_{,}\mathrm{D}_{,})+\ldots.$$

the means of obtaining the common extension of Taylor's Theorem to a function of two variables. Again, if we take $\phi x.\psi x$, and let D and $\mathrm{D}_{,}$ represent operations of differentiation, which separately affect ϕx and ψx, we have in the development of $(\mathrm{D}+\mathrm{D}_{,})^n\phi x.\psi x$, the formula for forming the nth differential coefficient of the product.

We shall conclude by some indication of the principal steps of the application of the calculus of operations to the solution of differential equations and equations of differences.

However much the calculus of operations may throw light upon the character and principles of algebra, it would at one time have been thought unlikely that it should much facilitate actual processes. It does this, nevertheless, and nowhere more than in the subject we are now going to describe. Solutions which by the usual method [Variation of Parameters] would never have been considered fit examples for an elementary work, on account of their complexity, may be represented with ease, and obtained in full with very little trouble.

When rules of algebra are true of the meanings of any symbols, all consequences of the use of these rules, all relations which are legitimate deductions from them, also represent truths. Not that these truths are always intelligible without subsequent interpretation: nor do we mean to say that, in the present state of the science, the interpretations are always attainable. And further, it may happen that theorems can be pointed out, derived from processes in which *some* only, and not *all*, of the fundamental rules of algebra are true. This does not prevent our right to deduce conclusions from such theorems, so long as we use no fundamental rules except those which are true of the expressions in question. For instance, we have seen that the operations of our calculus are not convertible with the operation of multiplying by a function of the variable. Thus if E stand for the direction to change x into $x+1$, Δ for that of forming the difference thence arising, and D for the direction to take the differential coefficient with respect to x, we have no right to say $\mathrm{E}\phi x(\psi x)=\phi x\mathrm{E}(\psi x)$, or $\Delta\phi x(\psi x)=\phi x\Delta(\psi x)$, or $\mathrm{D}\phi x(\psi x)=\phi x\mathrm{D}(\psi x)$; in which ψx is the function operated upon. But, when we thus use another function, ϕx, besides the one operated on, ψx, this convertibility of operations is the only rule of algebra which fails; it is therefore the only one the use of which we must avoid.

The operations E, Δ, and D, are closely connected with $\mathrm{E}+a$, $\Delta+a$, $\mathrm{D}+a$, of which they are particular cases; a being a constant, positive, negative, or nothing. We have

$$(\mathrm{E}-a).\phi x=a^{x+1}\Delta(a^{-x}\phi x)$$
$$(\Delta-a)\phi x=(a+1)^{x+1}\Delta\left((a+1)^{-x}\phi x\right)$$
$$(\mathrm{D}-a)\phi x=\epsilon^{ax}\mathrm{D}(\epsilon^{-ax}\phi x).$$

The first sides of these equations being representatives of $\phi(x+1)-a\phi x$, $\Delta\phi x-a\phi x$, and $\phi' x-a\phi x$. If these operations be repeated, we have

$$(\mathrm{E}-a)^m\phi x=a^{x+m}\Delta^m(a^{-x}\phi x)$$
$$(\Delta-a)^m\phi x=(a+1)^{x+m}\Delta^m\left((a+1)^{-x}\phi x\right)$$
$$(\mathrm{D}-a)^m\phi x=\epsilon^{ax}\mathrm{D}^m(\epsilon^{-ax}\phi x).$$

These results will also be found to be true when m is negative, by which means we are enabled to interpret $(\mathrm{D}-a)^{-1}$, $(\Delta-a)^{-1}$, and $(\mathrm{E}-a)^{-1}$ and their repetitions.

These same forms may be extended, as follows:—Let E_x and E_y severally denote the operations of changing x into $x+1$ and y into $y+1$; and let D_x, D_y, Δ_x, Δ_y, be similarly interpreted with respect to the differentiations and differences. We have then

$$(\mathrm{E}_x-a)^m(\mathrm{E}_y-b)^n=a^{x+m}b^{y+n}\Delta_x^m\Delta_y^n a^{-x}b^{-y}$$
$$(\Delta_x-a)^m(\Delta_y-b)^n=(a+1)^{x+m}(b+1)^{y+n}\Delta_x^m\Delta_y^n(a+1)^{-x}(b+1)^{-y}$$
$$(\mathrm{D}_x-a)^m(\mathrm{D}_y-b)^n=\epsilon^{ax+by}\mathrm{D}_x^m\mathrm{D}_y^n\epsilon^{-ax-by}$$

in which the function first operated upon is left out to save room. Here m and n may be either positive or negative integers. And even a or b may be symbols of operation, but not with respect to x or y. Thus

$$(\mathrm{D}_x-a\mathrm{D}_y)^m=\epsilon^{ax\mathrm{D}_y}\mathrm{D}_x^m\epsilon^{-ax\mathrm{D}_y},$$

in which the second side is to be thus interpreted. Changing y into $y-ax$, differentiate m times with respect to x, and then change y into $y+ax$.

We shall now give the heads of some methods of solution, observing that this article is intended only for those who can already master the same solutions by other methods.

Take the common linear equation—

$$a\frac{d^m y}{dx^m}+b\frac{d^{m-1}y}{dx^{m-1}}+\ldots,=\mathrm{X},$$

in which a and b are constants, and X a function of x. The operation performed upon y is $a\mathrm{D}^m+b\mathrm{D}^{m-1}+\ldots$: if this be called G, then y is the result of performing the inverse operation G^{-1} upon X. By the method explained in Fractions, Decomposition of, transform $(a\mathrm{D}^m+b\mathrm{D}^{m-1}+\ldots)^{-1}$ into $\mathrm{A}(\mathrm{D}-\alpha)^{-1}+\mathrm{B}(\mathrm{D}-\beta)^{-1}+$, &c., where α, β, &c. are the roots of the algebraical equation $ax^m+bx^{m-1}+\ldots=0$. Then y is

$$\mathrm{A}(\mathrm{D}-\alpha)^{-1}\mathrm{X}+\mathrm{B}(\mathrm{D}-\beta)^{-1}\mathrm{X}+\ldots$$
$$\text{or }\mathrm{A}\epsilon^{\alpha x}\int\epsilon^{-\alpha x}\mathrm{X}dx+\mathrm{B}\epsilon^{\beta x}\int\epsilon^{-\beta x}\mathrm{X}dx+\ldots.$$

substituting for D^{-1} its usual mode of expression. The arbitrary parts of the solutions will be obtained by the constants of integration in the usual manner. But the arbitrary part may always be obtained, in all inverse operations, by considering the function operated upon as $\mathrm{X}+0$, and operating separately upon X and 0. Thus $(\mathrm{D}-a)^{-3}\mathrm{X}$ may be completely expressed by

$$\epsilon^{ax}\left(\int dx\right)^3\epsilon^{-ax}\mathrm{X}+\epsilon^{ax}\left(\int dx\right)^3\epsilon^{-ax}0,$$

the second term of which is $\epsilon^{ax}(\mathrm{P}+\mathrm{Q}x+\mathrm{R}x^2)$, P, Q, and R being any constants.

Suppose that there are equal roots in the above equation, say three roots equal to a. The resolution of the fraction gives terms of the form

$$\mathrm{K}(\mathrm{D}-a)^{-3}+\mathrm{L}(\mathrm{D}-a)^{-2}+\mathrm{M}(\mathrm{D}-a)^{-1},$$

which contribute to the general value of y,

$$\epsilon^{ax}\left\{\mathrm{K}\left(\int dx\right)^3+\mathrm{L}\left(\int dx\right)^2+\mathrm{M}\int dx\right\}\epsilon^{-ax}\mathrm{X},$$

and the arbitrary part $\epsilon^{ax}(\mathrm{P}+\mathrm{Q}x+\mathrm{R}x^2)$.

---

[*] We transfer this word, with extension of meaning, to the calculus of operations.

The linear equation of differences corresponding to the above is

$$au_{x+n} + bu_{x+n-1} + \ldots = X,$$

where u_x is a function of x to be determined. The operation performed on u_x on the first side is $aE^n + bE^{n-1} + \ldots$

Every single root a, contributes to the solution a term of the form

$$A(E-a)^{-1}.X \text{ or } a^{x-1}\Delta^{-1}(a^{-x}X),$$

in which $\Delta^{-1}a^{-x}X$ may be any function of which the difference is $a^{-x}X$. If x be an integer, what is called $\Sigma(a^{-x}X)$ will do. Any set of equal roots contributes terms of the form

$$A(E-a)^{-k}X \text{ or } Aa^{x-k}\Delta^{-k}(a^{-x}X).$$

Any linear equation being given, in which either of the operations E_x, Δ_x, or D_x is combined with either E_y, D_y, or D_y, the form of the solution may be found. Take for example

$$\frac{d}{dx}u_{x,y} - au_{x,y+1} = X,$$

the operation performed upon $u_{x,y}$ on the first side is $D_x - aE_y$, and accordingly we have

$$u_{x,y} = \epsilon^{axE_y}\int \epsilon^{-axE_y}Xdx,$$

which is one form of the solution, and must be interpreted by expanding

$$\epsilon^{\pm axE_y} \text{ into } 1 \pm axE_y + \frac{1}{2}a^2x^2E_y^2 \pm \ldots$$

Another form can be obtained from

$$\left(E_y - \frac{1}{a}D_x\right)u_{x,y} = -\frac{1}{a}X.$$

We can only touch very briefly upon these points, and rather to show the existence of the system than to enter into it. Further details will be found in the *Library of Useful Knowledge*, in the 'Treatise on the Differential Calculus,' pp. 751-758.

The theorems answering to that of integration by parts, when $D-a$ and $E-a$ are used, are as follows. To save room let $D-a$ and $E-a$ be denoted by Θ and Λ. Then

$$\Theta^{-1}(PQ) = P\Theta^{-1}Q - \Theta^{-1}\left\{P'\Theta^{-1}Q\right\}$$

$$\Lambda^{-1}(PQ) = P\Lambda^{-1}Q - \Lambda^{-1}\left\{\Delta P.\Lambda^{-1}EQ\right\}$$

P and Q being functions of x, to which D and E refer, and P' meaning $dP : dx$. If $a=0$, the first becomes

$$\int PQdx = P\int Qdx - \int\left\{P'.\int Qdx.dx\right\},$$

which is the formula for integration by parts. And if Q be of the form Θ^nR, or Λ^nR, and P be a rational and integral function of a lower degree than the nth, the preceding operations carried on will show that $\Theta^{-1}(P\Theta^nR)$ and $\Lambda^{-1}(P\Lambda^nR)$ can be performed without leaving any trace of inverse operation in the result. Of the first of these it is a particular case that—

$$\int P\frac{d^nR}{dx^n}dx$$

can be found whenever P is a rational and integral function of a lower degree than the nth. Thus, P being of the second degree,

$$\Theta^{-1}(P\Theta^4R) = P\Theta^3R - P'\Theta^2R + P''\Theta R$$

$$\Lambda^{-1}(P\Lambda^3R) = P\Lambda^2R - \Delta P.\Lambda ER + \Delta^2P.E^2R.$$

By help of these theorems the intermediate equations of any linear equation can be readily discovered. Suppose, for instance, we have

$$(D-1)^5(D-2)^3y = X,$$

an equation of the eighth degree. There are eight equations of the seventh degree. Two of them are discovered at once by performing the operations $(D-1)^{-1}$ and $(D-2)^{-1}$ on both sides, giving

$$(D-1)^4(D-2)^3y = \epsilon^x\int\epsilon^{-x}Xdx,$$

$$(D-1)^5(D-2)^2y = \epsilon^{2x}\int\epsilon^{-2x}Xdx.$$

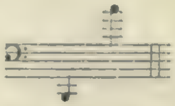
To find the other six, multiply separately by x, x^2, x^3, x^4, the simplest functions of their several degrees, and perform $(D-1)^{-1}$ upon all four results, and $(D-2)^{-1}$ upon the first two. This, by the preceding theorems, can be done. Thus, multiplying by x we have

$$(D-1)^5\left\{x(D-2)^2y - (D-2)y\right\} = \epsilon^{2x}\int\epsilon^{-2x}xXdx,$$

$$(D-2)^3\left\{x(D-1)^4 - (D-1)^3y\right\} = \epsilon^x\int\epsilon^{-x}xXdx,$$

which are two more of the required equations. To find the equations of the sixth degree, those of the seventh degree must be selected which admit of a repetition of the operation without leaving the inverse form $(D-2)^{-1}y$ or $(D-1)^{-1}y$: and the operation must be repeated; and so on.

OPHICLEIDE (ὄφις, "a serpent or snake," and κλεὶς, "a key"), a musical instrument of the inflatile kind, made of brass or copper, and intended to supersede the serpent—of which it is a decided improvement—in the orchestra and in military bands. It is a conical tube, the longest nearly 9 feet in length, terminating in a bell, like the horn. It has 10 ventages, or holes, all of which are stopped by keys, similar to those of the bassoon, only of larger dimensions, and is furnished with the same kind of mouth-piece as the serpent. The scale of the base ophicleide is from B, the third space below the base staff, to C, the fifth added space above it,—



including every tone and semi-tone within this compass. Music for the ophicleide is written in the base clef; for the alto, or *ophicleide quint*, in the treble clef. When the two instruments play together, the music for the alto is written an octave higher than that for the base.

The ophicleide was invented some years ago, in Germany. It is too noisy an instrument to be played in any but spacious buildings. There are several varieties of the instrument. In its early form it was used in the military bands of the northern sovereigns, when the troops of the allies occupied Paris. M. Labbaye, a manufacturer of musical instruments in that city, added new keys to it, and otherwise much extended its capabilities; besides which, he discovered a better mode of constructing the tube than had been practised, and thus greatly ameliorated its tone. These improvements were reported to the French Society of Arts in 1821 by M. Francœur, in consequence of which Labbaye obtained a patent for five years. The ophicleide first reached England in 1834, one of extraordinary dimensions having been manufactured abroad for the Birmingham Musical Festival of that year. In the Supplement to the 'Musical Library' for November, 1834, it is thus mentioned: "A new instrument, the *double-base ophicleide*, made for this festival, and now first introduced into England, proved eminently serviceable in the choruses, and whenever strength was required. The volume of sound it emits is immense, but the tone is rich, round, and blends well with the voices. We are much deceived if this instrument is not destined to operate a great change in the constitution of our orchestras: well played, it will answer the purpose of four double-bases, and is well calculated to form a third part to the bassoons, which has long been a desideratum. As a contra-basso to the trombones, it will not be found less useful." This prognostic has proved correct; the instrument is now become indispensable. Examples of its effective and judicious use are to be found in the 'Gloria,' and 'Marche Réligieuse' of Cherubini's third solemn mass, performed at the consecration of Charles X.

OPHIU'CHUS (the Serpent-bearer), one of the old constellations, representing a man holding a serpent, which is twined about him. But the moderns make a separate constellation of the serpent. [SERPENS.] Ophiuchus has also been called Anguitenens and Serpentarius. The figure of the man rests his feet upon the back of Scorpius, and is surrounded by Scorpius, Libra, Bootes, Corona, Hercules, and Aquila. It is not a constellation of any note, containing no star of the first, and only one of the second, magnitude. The number and insignificance of the mythological traditions connected with it are rendered less surprising by this paucity of remarkable stars, since the latter is a presumption that the constellation itself is of a later date than Orion or Ursa Major.

The following is a list of the principal stars:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
δ	1	5414	3
ε	2	5437	3·5
φ	8	5516	4

* Does not agree with Bayer.

† 65 of Flamsteed was either a mistake, or has disappeared.

OPHTHALMIA (from *ophthalmos*, ὀφθαλμος, the "eye") is an inflammation of the eye. General ophthalmia, or an inflammation of the whole globe of the eye, is a very rare occurrence. Cases however do occur, from severe injuries or other causes, in which the signs of all the special forms of ophthalmia are combined, and they are the most formidable affections to which the eye is liable. Unless met by the most active antiphlogistic treatment, they usually terminate in complete destruction of the organ.

In the large majority of inflammations of the eye, one part of it is alone or especially affected. Hence there have been described numerous varieties of ophthalmia, a distinct name being formed for the inflammation of each part or tissue by appending the termination *itis* to its anatomical name; as conjunctivitis, iritis, and corneitis, for the inflammations of the conjunctiva, iris, and cornea. [EYE, in NAT. HIST. DIV.]

Of all the varieties of ophthalmia, slight inflammation of the conjunctiva is the most frequent. It is the common result of all slightly irritating bodies being introduced between the eyelids, and of the application of cold, in which case it is often called catarrhal ophthalmia. Its symptoms are redness, varying from a pale-pink to a scarlet colour, of the external membrane of the eye and of the lining of the eyelids, the blood-vessels (which are naturally invisible) appearing swollen and tortuous, and making the front of the eye what is commonly called blood-shot; swelling of the eyelids and increased thickness and puffiness of the conjunctiva of the ball; and an increased secretion of opaque white or yellow tenacious mucus which agglutinates the eyelids. The pain is seldom acute, except in severe cases, in which it has a peculiar character, as if there were dust or fine sand rubbing between the eyelids. There is rarely any intolerance of light or any constitutional affection, and the vision is not at all affected, except by the swelling of the eyelids and the accumulated mucus.

In this, the common inflammation of the eyes, no active means need be employed. In severe cases, blood has been taken from the arm; but in general, the application of leeches, cooling lotions applied to the eyes, and mild purgatives or sweating medicines, are sufficient for the removal of the inflammation, which, as it does not affect a part directly important to vision, nor spread beyond the tissue first affected, rarely leaves any inconvenience behind. In the mild cases of this kind, a lotion composed of two grains of sulphate of zinc to the ounce of water is the best, and generally a sufficient remedy; the eyes should be washed with it three times a day.

That which is commonly called purulent ophthalmia is a much more serious form of inflammation of the conjunctiva. It was observed in its greatest severity in the European armies engaged in Napoleon's campaign in Egypt, and is therefore sometimes called Egyptian ophthalmia; and from its appearing to spread from one individual to another by the contact of the purulent matter secreted by the inflamed eyes, it has also received the name of contagious ophthalmia. In this form, which has often appeared as an epidemic, and is generally acknowledged to be liable to spread by contagion, all the symptoms of the preceding are greatly aggravated. The conjunctiva is intensely red, and so swollen that it is raised in a deep ring round the cornea, whose edges it overlaps so as almost totally to obstruct the sight. The conjunctiva of the eyelids is at the same time excessively inflamed, and by effusion into their loose cellular tissue they often become so distended that they completely cover the front of the eye. A considerable quantity of acrid yellow purulent discharge constantly flows between the eyelids, producing excoriations of them and of the cheeks. The pain is often extremely acute, vividly smarting, or hot and burning, and it is accompanied by some intolerance of light. From the conjunctiva, which it at first affects, the purulent ophthalmia often spreads rapidly to the other tissues of the eye; producing ulceration and sloughing, or excessive opacity of the cornea, and all the worst results of inflammation of the several tissues, even to suppuration and destruction of the whole of one or both eye-balls.

The treatment of this form of ophthalmia must be active in proportion to the rapidity of its destructive effects when unchecked. Bleeding, both general and local, may be employed, and purgatives and the various other antiphlogistic means should be administered, as in the treatment of any other acute inflammation. When the inflammation is somewhat checked, the greatest benefit is derived from the application of powerful astringents to the eye, a mode of treatment which may be adopted with equal advantage in these and in the severer cases of catarrhal ophthalmia. The best material is a solution of from two to four grains of lunar caustic to the ounce of water; of which one or two drops should be let fall into the eyes once or twice a day, according to the severity of the inflammation. This remedy produces considerable pain for a short time after its application, but is generally productive of the most beneficial results.

One of the most common effects of the purulent ophthalmia, when prevented by active treatment from producing its worst results, is a thickening and roughness of the inflamed lining of the eyelids, to which the name of granular conjunctiva is given. The affected surface looks like that of a florid ulcer, and the friction of its irregularities upon the front of the eye-ball keeps up a constant slight inflammation, of which the common consequence is a complete opacity of the cornea. The granular conjunctiva may be treated by the application of powerful astringents or caustics; the most efficient, though a severe remedy, is to touch the rough surface with a piece of sulphate of copper, taking care after its application that no considerable portion of it comes in contact with the front of the eye.

Infants of three or four days old are often the subjects of a very severe form of inflammation of the conjunctiva, to which the name of the ophthalmia of new-born children has been given. Its course and effects are similar to those just described, and it sometimes produces entire destruction of the eye before it attracts proper attention, for the eyelids are commonly agglutinated together by the discharge, and are so swollen that they obscure the front of the eye. Its severest form may be suspected when the upper eyelid is much swollen and is externally of a bright red colour. The treatment must be similar in its principles to that for the corresponding disease in the adult; in severe cases a leech should be applied to the temples, and purgatives should be administered in all; and when the inflammation is somewhat relieved, or from the first, if it be not very severe, astringent lotions should be dropped into the eyes. The best form is composed of from two to ten grains of alum in an ounce of water, beginning with the smaller quantity and gradually increasing the strength.

Another form of inflammation of the conjunctiva is that called strumous ophthalmia. It occurs in children of scrofulous habit, and is chiefly remarkable for the extreme intolerance of light by which it is accompanied. The patient cannot be induced to open the eyes, or even to raise them to the light, but keeps his head down, with the eyelids pressed together upon the ball of the eye, and carefully covered with his hands or his clothes. The degree of inflammation is by no means proportionate to the severity of this symptom; the conjunctiva is usually only a little reddened, but in many cases little pustular elevations form upon the edges of the cornea. The treatment of these cases should be chiefly that adapted for the constitutional disorder on which their peculiarities depend. [SCROFULA.] Pure air and exercise, mild aperients and tonics, and especially bark, iodine, and iron should be administered, and the general health should be carefully attended to. In the earlier stages a few leeches may be applied, but afterwards counter-irritation by blisters placed behind the ears, or by tartar-emetic ointment rubbed on the same parts, is most useful. Slightly astringent lotions may also be applied to the eyes, and the ulcers or little pustules on the cornea touched with the solid nitrate of silver (lunar caustic).

The characters of inflammation of the sclerotica are very different from those of inflammation of the conjunctiva, but very often the two affections are coincident, so that the appearances belonging to each are confounded. In sclerotitis, as this form of ophthalmia is sometimes called, the redness of the eye has a rose-pink or violet tinge, rather than the scarlet hue which is seen in the preceding form; for the distended vessels are fewer and smaller, and are to a certain extent obscured by the conjunctiva, beneath which they lie. This redness is most intense in a zone around the cornea, at which the enlarged vessels are concentrated like rays, and from whose outer border the redness diminishes in brightness till it is nearly lost at the angles of the eye; and by this circumstance sclerotitis is further distinguished from inflammation of the conjunctiva, in which the redness increases with the distance from the cornea. In sclerotitis there is always considerable pain of a dull heavy kind, which often extends all round the orbit, or over the forehead and head, and is accompanied by intolerance of light and a profuse secretion, not of mucus or pus, as in the preceding cases, but of hot tears. The pain is very often aggravated in the evening, or throughout the night.

The treatment of inflammation of the sclerotica must, as far as general means are concerned, be the same as for acute inflammation of the conjunctiva. The application of astringents or stimulants is useless, and sometimes injurious; the vapour of hot water and other warm fomentations are the local means which are most agreeable to the patient. The moderate use of mercury is generally useful. In rheumatic and gouty conditions of the system, with which this form of ophthalmia is often connected, and is then called rheumatic or arthritic ophthalmia, the treatment adapted to the general disorder should, as far as possible, be combined with those means which are proper for the local disease. [GOUT; RHEUMATISM.]

Inflammation of the cornea, corneitis, or keratitis, is very generally connected with some degree of the preceding. Its signs are those which are common to the inflammations of all the deep-seated tissues, namely, dull pain, intolerance of light, and profuse discharge of hot burning tears; at the same time a few vessels passing inward from the red zone around the cornea become visible upon its surface; it loses its transparency and becomes hazy, or assumes a grayish and often opaque chalky-white hue, from the deposition of lymph between its laminæ. [LEUCOMA.] In very severe cases suppuration takes place in the cornea, and it acquires a yellow colour and ulcerates; or matter is poured into the anterior chamber [HYPOPIUM], or the cornea is perforated by ulcers and the iris protrudes; or it sloughs and becomes soft and weak, so that staphyloma is produced.

The treatment of corneitis in its active state is the same as that for inflammation of the sclerotica. After the inflammation is subdued, its effects (which the situation of the cornea renders peculiarly important) admit of but little useful treatment. The opacity which remains, when it is superficial, is usually gradually removed, and that process may be in some degree assisted by the application of a weak solution of nitrate of silver or some other stimulant; the ulcerations generally proceed best when left to themselves, the chasms which they leave being gradually filled up, and the yellow tinge of the cornea which accompanies them being exchanged for a gray or bluish colour; the more serious effects, such as staphyloma, extensive leucoma, sloughing, protrusion of the iris, &c., are irremediable.

Inflammation of the iris has already been treated of. [Iritis.]

Inflammation of the membrane of the aqueous humour is not uncommon in young persons; it is marked by dullness and haziness of the cornea (which is surrounded by the vascular red zone formed by the distended vessels of the sclerotica), an alteration in the colour of the iris, which assumes a dull reddish hue and a turbid or purulent appearance of the aqueous humour, with, in some cases, hypopium. The proper treatment does not differ essentially from that of inflammation of the iris or sclerotica, with which this form of ophthalmia, like all the affections of the deep-seated tissues of the eye, is very generally conjoined.

The inflammations of the parts of the eye which are still more deeply seated are much rarer than any of the preceding; their symptoms also are more obscure, and they are seldom found uncombined with those of some other form of ophthalmia. Their signs are similar to those of the inflammations of the sclerotica and cornea; but the intolerance of light and the loss of vision are usually greater than would arise from the degree of inflammation which exists in the visible tissues. The treatment must be similar to that for the acute inflammation of the iris or cornea, and be actively administered; for the nature of the parts affected renders the least disorganisation of them of the highest importance.

All kinds of ophthalmia may either become chronic after having existed for some time as acute diseases, or may be chronic from their commencement. Their symptoms in either case differ only in degree from those of the corresponding acute forms, and the treatment of them should be the same in principle, though less active. Counter-irritation by blisters or other means, applied to the neighbourhood of the eyes, or setons in the back of the neck, are among the most useful means; and to the milder forms of astringent lotions some preparation of opium, as the *vinum opii*, may be added with advantage.

OPIANIC ACID. [Opium, Alkaloids of.]

OPIANINE. [Opium, Alkaloids of.]

OPIANO-SULPHUROUS ACID. [Opium, Alkaloids of.]

OPIANYL. [Opium, Alkaloids of.]

OPICI. [Osci.]

OPIUM, ALKALOIDS OF. Opium—the dried juice that exudes from incisions made in poppy heads while still growing on the plant—owes its well-known narcotic properties to certain organic bases or alkaloids. The number of these alkaloids at present known is seven; their names are—1. *Morphine*; 2. *Codeine*; 3. *Thebaine*; 4. *Papaverine*; 5. *Opianine*; 6. *Narcotine*; 7. *Narceine*. They exist in opium chiefly in combination with Meconic Acid, and associated with them are *opianyl* [Meconin], resinous matter, caoutchouc, fat, gum, volatile oil, lignin, and small quantities of inorganic salts. The following table exhibits the per-centage composition of four varieties of Smyrna (the best) opium, analysed by Mulder in the year 1836, and consequently before thebaine, papaverine, and opianine were rescued from the ill-defined matter called "gummy extractive:"—

	1.	2.	3.	4.
Morphine . .	10·842	4·106	9·852	3·800
Narcotine . .	6·808	8·150	9·360	6·546
Codeine . .	0·678	0·834	0·848	0·620
Narceine . . .	6·662	7·506	7·684	13·240
Meconine . .	0·804	0·846	0·314	0·608
Meconic acid . .	5·124	3·968	7·620	6·644
Fat . . .	2·166	1·350	1·816	1·508
Caoutchouc . .	6·012	5·026	3·674	3·206
Resin . . .	3·582	2·028	4·112	1·834
Gummy extractive	25·200	31·470	21·834	25·740
Gum . .	1·042	2·896	0·698	0·896
Mucus . . .	19·086	17·098	21·068	18·022
Water . . .	9·846	12·226	11·422	14·002
Loss . . .	2·148	2·496	0·566	3·334
	100·000	100·000	100·000	100·000

The morphia is however sometimes present to the extent of twelve, and in some French opium prepared in different parts of the Somme department even twenty to twenty-two, per cent. Constantinople opium varies somewhat, but is usually as rich in alkaloids as Smyrna opium, while Persian opium is generally poor in alkaloids, and Indian opium midway, in that respect, between the Smyrna and Persian varieties.

Separation of the opium principles from each other.—The methods by which any single constituent of opium is extracted are tolerably easy; the isolation of each one, however, from the same specimen of opium is a matter of far greater difficulty, and can only be successfully carried out by working with large quantities of raw material. Fortunately the operation is seldom or never necessary, and will only be given here as an illustration of the relations which the principles bear to each other. The following outline of the method adopted, is abridged from Miller's 'Chemistry,' vol. iii., p. 277.

Three pounds of opium are exhausted with water; from the insoluble residue *narcotine* may be extracted by digesting in acetic acid, precipitating with ammonia, and purifying with animal charcoal; from the evaporated infusion, neutralised with chalk, *meconic acid* is precipitated by chloride of calcium, and the meconate of lime farther treated as described under Meconic acid; the clear liquid filtered from the meconate of lime yields crystals of hydrochlorate of *morphine* on being concentrated; farther concentration of the liquid just named causes hydrochlorates of morphine and codeine to crystallise out, from which *codeine* is dissolved out by ammonia and afterwards reprecipitated by potash; ammonia added to the black mother liquor filtered from the hydrochlorates of morphine and codeine precipitates *thebaine* and *papaverine*, which are subsequently separated from each other by basic acetate of lead, while *narceine* and *meconin* remain in the ammoniacal solution; from the latter, narceine is precipitated by acetate of lead, and meconin then alone remains dissolved. *Opianine* has hitherto only been found in Egyptian opium.

1. *Morphine* ($C_{34}H_{19}NO_6 + 2Aq.$), *Morphia*, *Morphina*. This alkaloid derives its name from *Morpheus*, the god of sleep, in allusion to its narcotic properties. It was probably known during the 17th century, as Ludwig notices, in 1688, a substance called *magistery of opium*, possessing properties similar to those of the body in question. Morphine is found only in plants of the poppy tribe [Papaver, in Nat. Hist. Div.], and is generally combined with meconic acid, but sometimes with sulphuric acid.

Morphine may be extracted from opium in several ways. The 'London Pharmacopœia' directs that the opium be thoroughly exhausted with water, and chloride of lead added to the resulting strained liquor until no more precipitate of meconate of lead is thrown down; the filtrate is then evaporated to the crystallising point, the crystals of hydrochlorate of morphine purified from colouring matter by digesting with animal charcoal and recrystallisation, and morphine precipitated from the hydrochlorate by addition of ammonia.

Robinson's process, modified by Gregory, somewhat resembles that just described, but the aqueous infusion is first neutralised with carbonate of lime, and chloride of calcium is then used in the place of chloride of lead.

Mohr and Thiboumény's method is based on the solubility of morphine, and insolubility of the other bases, in lime water. It consists in thoroughly exhausting the opium by boiling two or three times in water, gradually adding the resulting decoction to boiling diluted milk of lime, filtering, evaporating, and neutralising the lime by chloride of ammonium, and finally purifying the morphine thus precipitated by treatment with animal charcoal and recrystallisation.

Estimation of morphine. M. Fordos has recently (1857) published a process for determining the amount of morphine contained in any specimen of opium. A weighed quantity is macerated with water for twenty-four hours, the insoluble portion triturated in a mortar, thrown on a filter, and washed three or four times with water. The whole of the liquors are then mixed together, and a third part of them treated gradually with ammonia until, after brisk agitation, a slight ammoniacal odour is perceptible; by this operation the quantity of ammonia necessary for the precipitation of the whole of the bases is known; the latter cannot, however, be at once collected, as much resinous and colouring matter is also thrown down by the ammonia. The next step therefore is to add an equal volume of alcohol to the remaining two-thirds of the mixed liquors, and then double the quantity of ammonia used with the one-third. The alcohol has the effect of keeping in solution all the resin and colouring matter; and although it retards the precipitation of the morphine, the whole of that alkaloid goes down in crystals after standing for three days, and may be collected on a tared filter, washed with ether and chloroform to separate narcotine, and finally weighed. The amount of opium recommended to be operated upon is fifteen grammes (231½ grains).

Morphine is colourless and inodorous, but has a persistent bitter taste. It crystallises in transparent prisms, is soluble in one thousand parts of cold, and four hundred of boiling, water. It is readily soluble in boiling alcohol, but insoluble in ether or chloroform; ammonia also dissolves it slightly. Its alcoholic solution communicates powerful left-handed rotation to a polarised ray. Heated, it parts with its water of crystallisation, melts, and on cooling solidifies into a radiated crystalline mass.

Morphine is exceedingly poisonous. It is a powerful base, combining with acids to form a well marked series of crystalline salts, of which the hydrochlorate and acetate are extensively used in medicine.

Hydrochlorate of morphine ($C_{34}H_{19}NO_6, HCl, + 6Aq.$), frequently called *muriate of morphia*, is a colourless, inodorous, bitter salt, which crystallises in plumose acicular crystals: it is soluble in 16 to 20 times its weight of water; and when boiling water is saturated with it, a crystalline mass is formed as it cools; it is also dissolved by alcohol. When exposed to a red heat, it is totally decomposed and dissipated. Its preparation from opium has already been described.

Acetate of morphine is prepared by dissolving the alkaloid in acetic acid, and evaporating the solution so that crystals may form; these are not however very readily procured, and by the evaporation of the solution a part of the acid is sometimes dissipated, and a portion of the acetate, suffering partial decomposition, is rendered insoluble in water.

The crystals are in the form of colourless radiating needles, which are very readily dissipated by exposure to heat and, like the other salts of morphine, are decomposed by ammonia, potash, and soda, the morphine being precipitated. Acetate of morphine is slightly deliquescent.

Meconate of morphine, which is the natural salt existing in opium, does not crystallise; it is soluble in water and in alcohol.

Sulphate of morphine ($C_{34}H_{19}NO_6, HO, SO_3 + 5Aq.$) crystallises in needles grouped in bundles; it is soluble in about twice its weight of water.

Bisulphate of morphine is procured by supersaturating the neutral salt with sulphuric acid; the excess of acid is to be removed by ether, which does not dissolve the bisalt.

Nitrate of morphine is obtained by dissolving the alkaloid in the acid; it assumes at first a fine deep orange colour, which afterwards becomes yellow, and, by the continued action of the nitric acid, oxalic acid is procured; when however dilute acid is used, a neutral salt is procured in the form of stellated crystals. It is soluble in 1½ part of water.

Phosphate of morphine crystallises in cubes, or in radiating bundles, when the acid is in excess.

Tartrate of morphine contains ($2C_{34}H_{19}NO_6, C_8H_6O_{12}, + 6Aq.$), and *bitartrate of morphine* ($C_{34}H_{19}NO_6, C_8H_6O_{12} + Aq.$). The *citrate* is said to be the morphine salt contained in "*black drop.*"

Sulphomorphide ($C_{68}H_{36}N_2O_{10}S_2$) containing the elements of sulphate of morphine less four atoms of water, is an amorphous substance produced by the action of excess of dilute sulphuric acid upon morphine: if binoxide of lead is also present a brown uncrystallisible matter termed *morphetin* results.

Iodomorphine ($C_{34}H_{19}NO_6, I_3$?). Obtained on triturating together equal parts of iodine and morphine, or on adding iodine to solution of sulphate of morphine and heating. It has a red-brown colour.

Methyl-morphine ($C_{34}H_{18}(C_2H_3)NO_6$) and *ethyl-morphine* ($C_{34}H_{18}(C_4H_5)NO_6$) are obtained as crystalline hydriodates by acting upon morphine with the iodides of methyl and ethyl respectively.

The general properties of the salts of morphine and the means of detecting their presence are as follow:—when nitric acid is dropped on crystallised morphine, a bright red or orange colour is the result; when morphine or one of its salts is acted on by a neutral solution of sesquioxide or sesquichloride of iron, a fine blue colour is the result, which disappears when an excess of acid is added, and reappears when the latter is saturated. Lassaigne proposes to detect the presence of the salts of morphine by evaporating the suspected solution at a temperature of 212°: the residue treated with alcohol dissolves the salt of morphine, and probably some other matters which may have been mixed with it; by spontaneous evaporation of the alcoholic solution the salt of morphine crystallises; from this, redissolved, ammonia throws down a precipitate which is recognised to be morphine by its bitter taste, alkalinity, solubility in alcohol, &c. Vegetable alkaloids as a general rule combine with iodic acid to form iodates; but when a solution of iodic acid is brought into contact with morphine or its salts, the liquid assumes a reddish brown colour, and exhales the peculiar smell of iodine, the presence of which may be detected by starch. According to Serullas, who proposed this test, a grain of morphine in 7000 grains of water may be detected by it.

2. *Codeine* ($C_{36}H_{21}NO_6 + 2Aq.$). This alkaloid derives its name from the Greek word *κώδη, a poppy head,* in allusion to its natural source. It exists in opium in far smaller quantity than morphine, the amount varying from two to eight parts in one thousand. Large quantities of it are, however, obtained as a bye-product in the preparation of morphine, and as a substitute for that alkaloid, it has of late years been much used on the continent. It readily crystallises on evaporating the liquors from which morphine has been precipitated by ammonia.

Codeine crystallises in large, colourless rhombic octohedra. It is soluble in eighty parts of cold, and seventeen of boiling water, and is also freely soluble in alcohol and in ether. Its solutions possess powerful lævo-rotation.

The salts of codeine are as great in number as those of morphine, and are even more readily obtained in large crystals: their constitution is also very similar. Iodide of ethyl combines with codeine to form hydriodate of *ethyl-codeine* ($C_{36}H_{20}(C_4H_5)NO_6$). Chlorine, bromine, and peroxide of nitrogen respectively give *chlorocodeine* ($C_{36}H_{20}ClNO_6 + 3Aq$), *bromocodeine* ($C_{36}H_{20}BrNO_6 + Aq.$) and *nitrocodeine* ($C_{36}H_{20}(NO_4)NO_6$). *Tribromocodeine* ($C_{36}H_{18}Br_3NO_6$) has also been obtained; and *iodocodeine* ($C_{36}H_{21}NO_6, I_2$), by a process similar to that for preparing *iodomorphine. Di-iodocodeine* ($C_{36}H_{19}I_2NO_6$) is a yellow crystalline precipitate formed on adding chloride of iodine to a strong solution of hydrochlorate of codeine. Cyanogen passed into a strong alcoholic solution of codeine is absorbed and after a time brilliant hexagonal plates of a new base *Cyanocodeine* ($C_{40}H_{21}N_3O_6 = C_{36}H_{21}NO_6, Cy_2$) are deposited. Cyanocodeine forms crystalline salts with acids.

3. *Thebaine* ($C_{38}H_{21}NO_6$), so called from *Thebes*, an ancient city of Egypt, the alkaloid having probably been first obtained from Egyptian opium. Pelletier thought it only an isomeric modification of morphine, and hence called it *paramorphine.* Its position among, and the method of its separation from, the other alkaloids, have already been indicated. It is not, like papaverine, precipitated from solution by subacetate of lead, but on separating the lead by sulphuric acid and adding slight excess of ammonia; it is then thrown down, and may be rendered colourless by treatment with animal charcoal and recrystallisation from alcohol.

Thebaine crystallises in colourless square plates of silvery lustre and acrid, styptic taste. It is insoluble in alkalies and in water, but readily so in alcohol or ether. It melts at 257° Fahr., and at a higher temperature is decomposed; is coloured red by sulphuric acid; rapidly attacked by nitric acid; with acids forms salts that crystallise with difficulty, or not at all; and, finally, is very poisonous.

4. *Papaverine* ($C_{40}H_{21}NO_8$). This base was discovered by Dr. Merck in 1848. It is separated from the lead compound already mentioned, by digesting in alcohol, filtering, distilling off the alcohol, treating the residue with hydrochloric acid, again filtering, evaporating, and setting aside, when hydrochlorate of papaverine gradually crystallises out.

Papaverine occurs in confused aggregated, acicular, white crystals. It is tolerably soluble in hot alcohol or ether, but insoluble in water. In contact with great excess of hydrochloric acid it separates in oily drops, and collects as a layer at the bottom of the vessel, but this layer gradually solidifies into a mass of crystals. Papaverine differs from the other opium alkaloids in giving a blue colour with strong sulphuric acid. The salts that it forms with acids are mostly difficultly soluble in water, and do not appear to be very poisonous.

5. *Opianine* ($C_{66}H_{36}N_2O_{21}$). This alkaloid seems to exist only in Egyptian opium, and occurs along with the morphine prepared from that variety of the drug. It is less soluble in alcohol than morphine and may therefore be separated by crystallisation. It forms long, colourless, transparent, brilliant needles; is precipitated from its solutions by ammonia as a white impalpable powder; is insoluble in water and cold alcohol, and not very soluble in boiling alcohol, the solution possessing a marked alkaline reaction, powerfully bitter taste, and is apparently as poisonous as an equally strong solution of morphine. The hydrochlorate forms double salts with the chlorides of platinum and mercury. Opianine is unaltered by strong sulphuric acid; is turned yellow by nitric acid; and blood-red changing to yellow by sulphuric acid containing nitric acid. It much resembles narcotine.

6. *Narcotine* ($C_{46}H_{25}NO_{14} + 2Aq.$) derives its name from the Greek *ναρκωτικὸς, narcotic;* its narcotic properties are, however, far inferior to those of morphine. It is extracted from that part of the opium that remains insoluble after exhaustion with water, by treating with dilute acetic or hydrochloric acid, and precipitating the filtrate with ammonia; the precipitate digested in boiling alcohol, filtered and allowed to cool, deposits the narcotine in crystals.

Narcotine occurs in opium to the extent of six to eight per cent. It crystallises in colourless right rhombic prisms, inodorous, but of bitter taste. It is insoluble in cold water; only soluble in seven thousand parts of boiling water; insoluble in caustic alkalies, but soluble in ether, alcohol, and the fixed and essential oils. Its alcoholic solution exerts lævo-rotation on polarised light, but dextro-rotation if excess of an acid is present. It is coloured blood-red by sulphuric acid containing nitric acid. By heat it fuses and gives off water, and at a higher temperature than 340° Fahr. is decomposed.

Narcotine combines with some of the acids, but the resulting salts are somewhat unstable and crystallise with difficulty. The *chloroplatinate* contains ($C_{46}H_{25}NO_{14}, HCl, PtCl_2$). The *sulphate* is decomposed, when boiled with dilute sulphuric acid, into a dark green amorphous powder termed *sulphonarcotide* ($C_{92}H_{48}N_2S_2O_{32}$), that is to say, the elements of neutral sulphate of narcotine less four atoms of water: if some binoxide of lead is also present a brown amorphous alkaloid termed *narcetine* results.

Narcotic acid is produced as an oleaginous potash salt, on boiling narcotine for some time with strong caustic potash.

Humopic acid is a dark brown amorphous body formed on heating narcotine in an oil bath to a few degrees above its fusing point.

Cotarnine ($C_{26}H_{13}NO_6 + 2Aq.$) is produced when narcotine is acted upon by oxidising agents. It forms starry groups of colourless needles, slightly soluble in cold water, more so in hot water, insoluble in potash, but soluble in alcohol, ether, and ammonia. It readily combines with acids to form salts. The *hydrochlorate* contains ($C_{26}H_{13}NO_6, HCl, + 5Aq.$), and crystallises in long silky needles.

Opianyl ($C_{20}H_{10}O_8$) (Gerhardt's *hydride of opianyl* ($C_{20}H_9O_8, H$), accompanies cotarnine under the circumstances just mentioned. It is identical with the meconin that exists naturally in opium. It occurs in acicular crystals. Nitric acid converts into *hyponitromeconic acid,* or *nitromeconin.* [MECONIN.]

Apophyllic acid ($C_{16}H_7NO_8$), so called from the resemblance of its crystals to those of the well known mineral *apophyllite,* is produced by the breaking up of cotarnine on prolonging the oxidation of narcotine; the opianyl is also then broken up into hemipinic and opianic acids.

Hemipinic acid ($C_{20}H_{10}O_{12} + 4Aq.$) crystallises in colourless rhomboidal prisms. It is volatile and condenses in brilliant plates. *Ethylhemipinic acid* contains ($C_{20}H_9(C_4H_5)O_{12} + 3Aq.$).

Opianic acid ($C_{20}H_{10}O_{10}$) (Gerhardt's *hydrated oxide of opianyl* $\left.\begin{matrix} C_{20}H_9O_8, O \\ HO \end{matrix}\right\}$) is a tolerably abundant product of the energetic oxidation of narcotine. It crystallises in small, shining, silky prisms; is slightly soluble in cold water, more so in hot water, and also in alcohol;

reacts as an acid; readily melts but does not appear to be volatile. The lead and silver salts occur in thin shining prisms and flakes. Sulphurous acid converts it into *opiano-sulphurous acid* ($C_{20}H_8O_8$, S_2O_4 ?).

Sulphopinic acid ($C_{20}H_{10}O_8S_2$) (Gerhardt's *sulphide of opianyl* $\left.\begin{matrix}C_{20}H_9O_8.S\\HS\end{matrix}\right\}$) is produced on passing sulphuretted hydrogen into a solution of opianic acid kept at a temperature of about 158° Fahr. It crystallises from alcohol in slender needles.

Opiammon ($C_{40}H_{19}NO_8$), (Gerhardt's *nitride of opianyl and hydrogen* $N\left\{\begin{matrix}C_{20}H_9O_8\\C_{20}H_9O_8\\H\end{matrix}\right)$ is a pale yellow crystalline powder obtained on evaporating a solution of opianate of ammonia. Caustic potash partly converts it into *xanthopenic acid.*

Teropiammon ($C_{60}H_{29}NO_8$), (Gerhardt's *nitride of opianyl* $N\left\{\begin{matrix}C_{20}H_9O_8\\C_{20}H_9O_8\\C_{20}H_9O_8\end{matrix}\right.$ $+2\,HO$) is formed when narcotine is acted upon by dilute nitric acid. It crystallises from boiling alcohol in thin colourless needles.

Narcogenine ($C_{72}H_{38}N_2O_{20}$) was the name given by Blyth to the base in a platinum salt that he obtained after oxidising narcotine. It appears however to be merely a combination of the chloroplatinates of narcotine and cotarnine.

Alcohol-radical derivatives of narcotine. From the experiments of Wertheim it would seem that narcotine ($C_{46}H_{25}NO_{14}$) contains ethyl; he therefore represents its composition by the formula ($C_{42}H_{20}(C_4H_5)NO_{14}$), looks upon opianine ($C_{42}H_{21}NO_{14}$) as normal narcotine ($C_{42}H_{20}(H)NO_{14}$), and has succeeded in obtaining a methyl derivative ($C_{42}H_{20}(C_2H_3)NO_{14}$), and a propyl derivative ($C_{42}H_{20}(C_6H_7)NO_{14}$).

7. *Narceine* ($C_{46}H_{29}NO_{18}$). *Narceia.* So called from *νάρκη, stupor.* From the lead with which it is combined in the precipitate already mentioned, narceine is separated by sulphuretted hydrogen; the filtrate after evaporation to a syrupy consistence deposits silky crystals of narceine.

Narceine, purified by recrystallisation, occurs in colourless needles soluble in boiling water and in alcohol, but insoluble in ether. It is more fusible than morphine, or narcotine, and does not seem to be poisonous. Concentrated sulphuric acid colours it intensely red, changing to green on application of heat. Iodine gives it a deep blue colour. It forms crystalline salts with most of the acids, though in basic power it is somewhat feeble. The *hydrochlorate* contains ($C_{46}H_{29}NO_{18}$, HCl).

Porphyroxin (from *πορφύρεος, purple,* and *ὀξύς, acid*) is, according to Merck, another principle contained in opium. It is said to be a crystalline resin, and on its turning red when paper wetted with its ethereal solution is exposed to warm hydrochloric acid, is founded a test for the presence of opium in a compound mixture.

Pseudomorphine ($C_{27}H_{18}NO_{14}$?) is, according to Pelletier, occasionally met with in opium. It somewhat resembles morphine but does not form salts, is not affected by iodic acid, and apparently is not poisonous.

OPIUM, MEDICAL USES OF. [PAPAVER.]

OPIUM TRADE. The principal countries in which opium is prepared are India, Turkey, and Persia. The poppy is cultivated in Egypt and Arabia; in Italy, France, and other parts of Europe; but, with slight exceptions, rather for the sake of its capsule and the oil extracted from its seeds than for the inspissated juice. Indian opium is of three kinds, of which the chief are Patna, grown in the province of Bahar, and Benares, the former of which is most esteemed; the third kind, produced in the district of Malwa, is still less esteemed than that of Benares. The best Indian opium, however, is inferior to that of Turkey. For some time the quantity of opium produced and brought to the Eastern markets from all parts was not equal to the demand, and the Malwa and Turkish opium were introduced to supply the deficiency. At first there was a strong prejudice against the latter. The Turkey opium was introduced into the Indian Archipelago in 1815, and the merchants reluctantly consented to its constituting one-fourth of the supply for the year; but two years afterwards they expressly stipulated for one-half, and in the following year for three-fourths, although the price rose, while Indian opium was stationary. A strong preference has also been shown in China for the Turkish opium, which has been introduced by the Americans. Several thousand persons are engaged in the cultivation in Turkey; they are generally very poor, and the quantity annually brought to market by each cultivator does not exceed one or two baskets. The annual average produce of Turkey was estimated some years ago at about half a million pounds. The whole quantity of land under the poppy cultivation in India is said not to exceed 100,000 acres. Milburn ('Oriental Commerce,' p. 224) gives the following account of the opium monopoly, as maintained at a time when the East India Company was at the height of its power:—"The monopoly in the trade of opium, or the cultivation of the poppy, may be traced at least as far back as the commencement of the British influence in Bengal. The advantages resulting from it were for several years merely considered as a part of the emoluments of certain officers under the government. In the year 1773 the trade was taken out of their hands, and the profit assumed for the benefit of the Company. The provision of the article was for many years let out upon contract. The opium trade continued under the direction of the Board of Revenue till 1793, when it was transferred to the Board of Trade. On the expiration of the contracts, in 1797, the cultivation of opium was restricted to Bahar and Benares, and discontinued in Bengal: the mode of provision by agency was resorted to, and still continues in practice. In July, 1799, some regulations were published 'for the guidance of all persons concerned in the provision of opium on the part of government, and for preventing the illicit cultivation of the poppy and the illicit importation or traffic in the article of opium.' Under these regulations, which were further modified in 1807, the cultivation of the poppy, except on account of government, is expressly forbidden; but it is left entirely at the option of the cultivator to enter into engagements on account of government at a settled price, or to decline it altogether." Of recent events in the opium trade we shall speak presently.

Opium is often adulterated with the pulverised leaves and stalks of the poppy, which are mixed up into a mucilaginous mass with gum arabic or some similar substance. In Sumatra the opium prepared for smoking is frequently adulterated with pine-sugar, and crude opium with the fruit of the pisang, or plantain. An engrossing taste for opium pervades all classes in China, and has spread with astonishing rapidity. From the superior classes, who were the first to practise it, the habit of opium smoking has descended and become general. "Worthless subordinates in offices and nefarious traders," says Sir J. F. Davis, "first introduced the abuse; young persons of family, wealthy citizens, and merchants, adopted the custom; until at last it reached the common people. I have learned on inquiry, from scholars and official persons, that opium smokers exist in all the provinces, but the larger proportion of them are to be found in the government offices; and that it would be a fallacy to suppose that there are not smokers among all ranks of civil and military officers below the station of provincial governors and their deputies." Gutzlaff says of the Chinese sailors, that most of them are smokers of opium, and that when the weather is rough, and more than ordinary attention is required from them, they turn in and intoxicate themselves with this drug; and on shore they indulge in smoking it until all their wages are squandered. The tribes of the Indian Islands more frequently smoke opium than eat or chew it. They in fact chew tobacco and smoke opium, while the practice of the Turks and other people of Asia is directly the reverse. Raffles states that in Sumatra the opium prepared for smoking is used along the coast, whereas crude opium is chewed by the people of the interior. On the west coast of Celebes, the principal rajah and his family, and the various smaller rajahs amongst whom the country is divided, are the chief opium smokers: persons of inferior rank not being able to command the luxury. In some parts of India, opium is presented at visits and entertainments in the same familiar manner as a snuff-box in Europe. The prohibition of intoxicating liquors by the Mohammedan law has, it is believed, encouraged the habit of taking opium; and in consequence of the Turks of the present day being far less bigoted than formerly, the consumption of opium is said to have declined with the more frequent indulgence in wine and arrack. The habit is believed to be more prevalent at present in Persia than in Turkey, though it is not often carried to the same excess. In Europe opium is almost wholly employed as a medicine; it has been made in England from the native poppy, but the cultivation is not likely at any time to become worthy of attention on a large scale. The opium consumed in this country is chiefly from Turkey. Opium in small quantities is a permanent article of import from Italy and France; occasionally, but in still less quantities, it is imported from Russia, Germany, Holland, and Belgium; rarely from India. Within the last few years Egypt has exported opium to England, and the quantity has been yearly increasing. The supply received from each country is liable to great fluctuations, on account of the uncertainty of the crop.

It is in the relations between India and China that the opium trade is most important. Some authorities have stated that opium has always been prohibited in China; but this does not appear to have been the case. It was a legitimate branch of trade down to the close of the last century, prohibitory regulations having been first made in 1796. From this period the trade has always been contraband; and yet in little more than forty years the consumption of Indian opium in China rose from 1000 to 27,000 chests per annum. Opium constituted about one-half of the total value of British imports into Canton just before the opening of other Chinese ports to the British. Nothing but the extraordinary corruption of the Chinese authorities can account for this increase of a trade prohibited by the laws; but it is another proof of the difficulty of putting in force regulations which are at variance with the popular habits and taste. Macao was at first the centre of the Indian opium trade; but in 1802, in consequence of the conduct of the Portuguese towards the British merchants, the trade was removed to the island of Lintin. Here the opium was kept stored in armed ships, and delivered to the Chinese by written orders from Canton, on the sale being concluded and the money paid at that place. The price gradually fell, and the quantity imported gradually increased. Imperial edicts were frequently issued against opium dealers and smokers, but with little effect. There is reason to believe that the Chinese government was less alarmed about the introduction of opium, than at the drain of bullion which the opium trade occasions. Formerly the produce of China was paid for in silver, but opium has so successfully served the purpose as a medium of commercial exchange, that it has been less necessary to employ coin or bullion. The opium trade has thus been the means of draining China of the precious metals. The Chinese do not regard gold and silver as signs of wealth merely, but as wealth itself; and in many of their public documents relating to the opium trade the export of silver is also noticed; in some cases it is difficult to ascertain which is considered the paramount grievance. In 1836 an officer of the Chinese government proposed that opium should be rendered a legitimate article of commerce, and that the cultivation of the poppy should be permitted. Extraordinary as it may appear, the poppy is cultivated in at least six different provinces in China with the connivance of the local functionaries.

So important a source of revenue has the opium monopoly become to the Indian government, that war with China has been regarded as a less evil than a surrender of this privilege. The government is not the grower of the poppy, but controls the growers in an extraordinary way. None must be grown in Benares or Patna, except that of which the juice is sold to the government at a fixed price. No one is obliged to cultivate the plant, and therefore the government offers such a price as will just stimulate production; and this price is about 9*d.* per lb. for the juice, on an average of years. The government buys the whole produce, be it large or small, at this price. The poppy-fields are measured every year, and their boundaries fixed, in order to prevent collision among those to whom they are assigned. When the poppies are ripe, agents make a circuit of the district, and form by guess a probable estimate of the produce of each field; and the cultivators are made to sign an agreement to deliver the quantity thus estimated, and as much more as the field will yield. The rigour of the law is brought to bear upon those cultivators who depart from the agreement; they may cultivate the poppy or not as they please; but if they do, they become bound to the government in a most stringent way. The thickening of the juice by inspissating, the making up into balls, the classifying into qualities, and the packing in chests made of mango-wood (holding on an average about 140 lbs. each)—cost the government about 3*s.* per lb.; making, with the cost of the juice itself, something under 4*s.* per lb. on an average. Malwah is not a British possession, and the monopoly, therefore, cannot extend to that region; but the government, nevertheless, obtains a large revenue from Malwah opium, by imposing a frontier duty on all opium sent to Bombay or other ports for shipment; Malwah itself having no seaboard. Until 1834 the East India Company sent their own opium in their own ships for sale in China or elsewhere; but when the trading powers of the Company were abolished, a new system was organised. The opium from Patna and Benares is sold by auction. When packed in the chests, it is sent from the depôts at those two cities to Calcutta, where it is sold by auction to the highest bidders, who carry it to any market they please, but nearly all to China. The auction price has varied from 7*s.* to 21*s.* per lb., in different years; but the average is about 12*s.*, of which 8*s.* is clear profit. These auctions are held ten or twelve times in the year. The government not only pays the cultivator for his opium, but advances him money to assist in the culture: a system which throws him much into the power of the government agents. In the accounts of the Indian Revenue and Expenditure, annually laid before parliament, there are always items for—advances to opium-cultivators; purchase of poppy leaves; purchase of opium juice; packing and transit expenses; salaries of agents; and expenses of sale. So important to the exchequer of India is the 4,000,000*l.* or 5,000,000*l.* now annually derived from opium, that, though often objected to, it still remains untouched. The Marquis of Dalhousie, in 1856, published a minute, giving a sketch of the improvements which had been made in India during his Governor-Generalship from 1848 to that year; he spoke with pleasure of the opium-revenue, but said nothing about the *morale* of the trade. During the Indian mutinies of 1857-8, the opium-cultivators were much disturbed, and much of their property was destroyed; but the relations between the government and the cultivators continued as before. The transfer of the government from the East India Company to the Queen, in 1858, made very little if any change in these relations.

The above slight sketch of the opium-trade in reference to India may usefully be followed by a few words concerning the proceedings in China. The opium of India is chiefly bought by English and American merchants, who send most of it to China in low-hulled swift sailing vessels. Other portions go to Malaya, Sumatra, Borneo, Celebes, and other places in the East. The augmentation of price becomes enormous, either by a monopoly of the trade to native princes, or by the imposition of a high duty. The opium clippers sent to China are mostly armed for self-defence, seeing that the trade is an illegal one in the eyes of the government, or is at least never openly recognised. There are always Chinese merchants willing to assist the English merchants in the traffic, and Chinese officials willing to be bribed into connivance; and hence there is very little difficulty in getting the opium landed on shore, in exchange for Sycee silver. There are no bills, bonds, or barter; pure solid silver, at so much per oz. is insisted on as the medium of purchase. It has been conjectured that the merchants obtain somewhat over a guinea a pound for the opium, in an average of years; but there are no means of determining this; whatever it may be, this price is enormously increased by the time the opium smokers and chewers obtain the drug in the interior of China. When, on the cessation of the East India Company's trading powers in 1834, a "Superintendent of Trade" was sent to China by the British Government, this superintendent was perpetually engaged in broils with the Chinese government concerning the opium trade; these broils led to the seizure and destruction of 20,000 chests of opium by the Chinese officials in 1839; and this seizure led to a state of hostilities which has had little intermission between 1839 and 1860. We refer to the articles CANTON, CHINA, HONGKONG, &c. in the GEOG. DIV. for an account of the various transactions in which Lin, Keshen, Kwan, and Ke-guy, figured on the part of the Chinese, and Davis, Elliott, Maitland, Brewer, Gough, Parker, and Pottinger on the side of the British.

OPOPO'NAX CHIRO'NIUM (Koch), a native of the south of Europe, and also of Asia Minor, a tall plant, often 8 feet high, from the base of the stem or summit of the root of which, when wounded, flows a yellow milky juice, which hardens on exposure to the sun and air. It occurs either in tears or in masses called placentæ. The tears are globose or angular, fatty to the touch, externally brownish-yellow, fragile, and, on being triturated, yield a yellow powder. The odour is strong, somewhat nauseous, resembling ammoniacum with a bitter balsamic taste. The specific gravity is 1·622.

Its constituents are resin, gum, and volatile oil. In its action on the human system it corresponds with the other gum-resins of the *Umbelliferæ.* [ASAFŒTIDA.] The *Ferula Hooshee*, a native of Beloochistan, produces a gum called hooshee, which, though not collected, resembles the opoponax of the European shops.

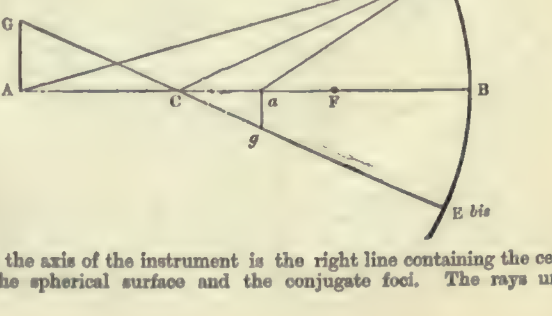
(Royle, *Flora of the Himalaya*, p. 231.)

OPPOSITION. [CONJUNCTION AND OPPOSITION.]

OPTIC AXIS. The line or lines in a doubly-refracting crystal in the direction of which no double refraction takes place, is termed the *optic axis* or *axes*. Iceland spar has but one optic axis, and this coincides with the axis of the rhombohedron. In uniaxal crystals the optic axis is identical with the geometrical. When the doubly-refractive forces neutralise each other, so that there is no double refraction in a particular direction, a line along that direction is sometimes termed the *resultant axis*. In uniaxal crystals the course of the extraordinarily refracted ray [REFRACTION; POLARIZATION] is constant for each crystal with relation to the optic axis; it is either refracted towards it, relatively to the ordinary ray, when the crystal is said to have a *positive* optic axis; or bent from it, when the crystal is said to have a *negative* axis.

OPTICS is that branch of physical science which explains the formation of images, as depending on the known laws by which the modifications of light are governed. [LIGHT.] These images are formed either by polished reflecting surfaces or by transparent refracting media. In the former case, the angles of incidence and reflection are equal; in the latter, the sines of the angles of incidence and refraction are in a constant ratio for one and the same medium. The position and magnitude of the image of an object is easily ascertained, when we have previously ascertained the position of the image of a point, in reference to the position of the point itself and of the reflecting or refracting instrument; in other words, when we have found the relation between the conjugate *foci*, so called because it universally holds in optics, that whichever focus be considered the object, the other will be the image. The *principal focus* of an instrument is that to or from which a pencil of parallel rays falling perpendicularly (or nearly so) on the instrument is made to converge or diverge after reflection or refraction. In a plane mirror the conjugate foci are similarly situated at opposite sides of the mirror [LIGHT]; consequently in this instance the instrument has no principal focus. Generally, the distance of the principal focus from the instrument is called the focal length of that instrument, whether a reflector or a refractor. Since conjugate foci are mutually such, it follows that rays proceeding from the principal focus will, after reflection or refraction, emerge in a *parallel* pencil. We shall now proceed to the relations existing between the conjugate foci of spherical reflectors, observing that the axis of the instrument is the right line containing the centre of the spherical surface and the conjugate foci. The rays under

Fig. 1.



consideration are those which are directed nearly along the axis, and which therefore fall exceedingly nearly perpendicularly on the reflector.

Let D B E represent the section of a spherical reflector made by a plane passing through its axis, C its centre, A the focus of incident rays, A D an incident ray, A D C is the angle of incidence. Make the angle a D C = A D C, then a D C is the angle of reflection, and if the point of incidence D were infinitely near to the point B in the axis, then all the reflected rays of which the incidence was nearly perpendicular would converge to a, the latter would then be the focus conjugate to A, for if rays diverged from a they would after reflection evidently converge to A.

Now, if a straight line as C D bisect an angle of a triangle, as the angle A D a, it will divide the base into segments A C, C a proportional to the adjacent sides A D, D a ('Euc.,' book vi.), that is, A C : C a : : A D : D a; but when D is infinitely near to B, we may write A B and B a instead of A D and D a, in which case we should have A C : C a : : A B : B a. Let A B = Δ, a B = Δ', and the radius C B = r; then A C = $\Delta - r$; C a = $r - \Delta'$; whence $\Delta - r : r - \Delta' :: \Delta : \Delta'$, or $\Delta'(\Delta - r) = \Delta(r - \Delta')$; therefore $2\,\Delta\,\Delta' = r(\Delta + \Delta')$, which may be also written in the form $\frac{1}{\Delta} + \frac{1}{\Delta'} = \frac{2}{r}$. We should have precisely the same investigation if we had supposed rays as E D to fall on the convex side converging to a focus A; but being reflected in the direction D e, they would appear to diverge from the conjugate focus a: hence the above formula applies to two cases,—namely, when diverging rays fall on the concave surface, or converging rays on the convex surface, of a spherical reflector.

Example 1.—A candle is placed before a concave speculum at a distance of 3 feet from it: what will be the distance of its image from the same, the radius of the speculum being 2 feet!

Here we have given $\Delta = 3$ feet, $r = 2$ feet, and to find Δ' we substitute these numbers in the general formula $\frac{1}{\Delta} + \frac{1}{\Delta'} = \frac{2}{r}$, which thus becomes $\frac{1}{3} + \frac{1}{\Delta'} = \frac{2}{2} = 1$; whence $\frac{1}{\Delta'} = \frac{2}{3}$, and therefore $\Delta' = \frac{3}{2} = 1\tfrac{1}{2}$ foot; the image will consequently be 1 foot 6 inches in front of the speculum.

It being sometimes convenient to measure the distances of the foci from the centre instead of the surface of the speculum, it is easy to find a proper formula from the proportion we have established—namely, A C : C a : : A B : B a. Let A C = ρ, C a = ρ'; then A B = $r + \rho$, a B = $r - \rho'$, whence $\rho : \rho' :: r + \rho : r - \rho'$, or $\rho(r - \rho') = \rho'(r + \rho)$, therefore $r(\rho - \rho') = 2\rho\rho'$, consequently $\frac{1}{\rho'} - \frac{1}{\rho} = \frac{2}{r}$; thus, in the example given above, we find (since $\rho = 1$ and $r = 2$) $\frac{1}{\rho'} - 1 = 1$, or $\frac{1}{\rho'} = 2$; therefore $\rho' = \frac{1}{2}$, which is agreeable with the former result.

When the incident rays proceed from a point exceedingly distant (as the sun for instance), then Δ being very great $\frac{1}{\Delta}$ will be exceedingly small and may be rejected, in which case we have $\frac{1}{\Delta'} = \frac{2}{r}$ or $\Delta' = \frac{r}{2}$, that is, parallel incident rays are made after reflection to converge to F, the middle point of the radius C B. Hence the focal length of a spherical speculum is one-half that of its radius.

In examining the formula for the positions of the conjugate foci, namely, $\frac{1}{\Delta} + \frac{1}{\Delta'} = \frac{2}{r}$, we find that when $\Delta = r$ we also must have $\Delta' = r$; hence when the focus A is at C the centre, the conjugate focus a will be at the same point. If A move to the left of C (in *fig.* 1), Δ being then greater than r, $\frac{1}{\Delta}$ is less than $\frac{1}{r}$, and therefore $\frac{1}{\Delta'}$ must be greater than $\frac{1}{r}$ or Δ' is less than r, and as Δ increases to greater magnitudes, Δ' accordingly diminishes, until Δ becomes infinite, when Δ', as we have seen, becomes $\frac{r}{2}$: hence, whilst A moves on the left indefinitely from C, the other focus moves on the right from C as far as the principal focus F.

With respect to the images formed by concave specula, let A G represent a small object at A, the line A G being perpendicular to A C, join G C, then G C E will be the axis of the speculum when G is considered the focus of incident rays, and its conjugate focus g can be found by the preceding formula: hence $a\,g$ will be the image of A G, its position is evidently inverted, and it is easy to see that the line $a\,g$ is very nearly perpendicular to C B; and by similar triangles, the linear dimensions of the image $a\,g$ are to those of the object A G as C g : C G, or as $\rho' : \rho$. Now the formula $\frac{1}{\rho'} - \frac{1}{\rho} = \frac{2}{r}$ gives $\frac{\rho'}{\rho} = \frac{r}{2\rho + r}$; hence the image (in respect to linear dimensions) is less than the object in the ratio of $r : 2\rho + r$ (or since $\rho = \Delta - r$) as $r : 2\Delta - r$; on the contrary, if the object be placed between the centre and principal focus, as at $a\,g$, then A G would become the image; for A G : $a\,g$: : $\rho : \rho'$; but $\frac{\rho}{\rho'} = \frac{r}{r - 2\rho'} = \frac{r}{2\Delta' - r}$; therefore A G : $a'g$: : $r : 2\Delta' - r$; which shows that the image is then greater than the object, or magnified. From the principles of geometry it follows that the surfaces of the image and object are as the squares of the linear dimensions, and the apparent volume, or bulk, as their cubes.

Example 2.—An object is placed at a distance of 12 feet in the axis of a concave speculum of two feet radius: to find how much it will appear diminished in its image, with respect to its linear, superficial, and solid dimensions.

Here $r = 2$, $\Delta = 12$, $2\Delta - r = 22$; therefore

for linear dimensions Image : Object : : 2 : 22,

that is : : 1 : 11;

for superficial do. the ratio is as 1 : 121, and for apparent bulk it is as 1 : 1331.

Heat being capable of reflection, like light, the rays of the sun may be collected by a concave speculum in its principal focus (or burning-point) F.

Example 3.—To find how much an object will be magnified by the same speculum, when placed 1 foot 6 inches in front of it.

Here $\Delta' = 1\tfrac{1}{2}$, $r = 2$, $2\Delta' - r = 1$; therefore in linear dimensions the ratio is as 2 : 1;

in superficial as 4 : 1;
and in cubical as 8 : 1.

Let us next consider the relation between the conjugate foci when diverging rays fall on a convex spherical speculum, which will also be the relation when converging rays fall on a concave speculum as will be evident by inspection of the figure (*fig.* 2). Employing the same letters with the diagram as before, C will be the centre, A the focus of incident rays, a of reflected rays, &c.

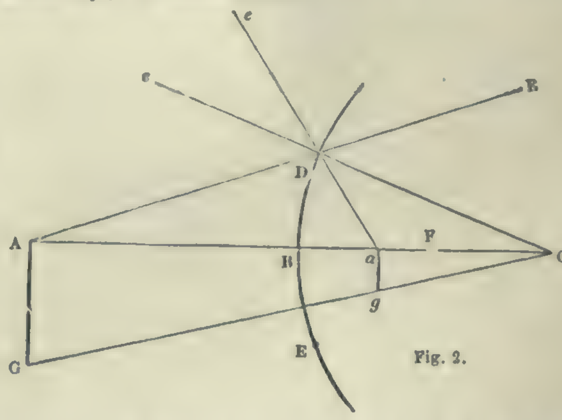


Fig. 2.

Let A D be an incident ray near the axis A C, join C D and produce to c; make the angle of reflection c D e equal to the angle of incidence A D c, and produce the reflected ray D e to meet the axis in a; then when D is infinitely near B, a is the focus conjugate to A. The same figure would equally apply if we had supposed rays E D converging to A to fall on the concave surface, for since the angles A D c, c D e, a D C, C D E are all equal, D a would then be the actual reflected ray and therefore a would be still the focus conjugate to A. Now since the external angle a D E of the triangle A D a is bisected by the straight line D C, it follows (Simson's 'Euc.,' book 6) that A C : C a : : A D : D a (and D being supposed infinitely near to B in order that the rays may be incident nearly perpendicularly) : : A B : B a. Let A B = Δ, a B = Δ', C B = r, C A = ρ, C a = ρ', then we have

$$\rho : \rho' :: \Delta : \Delta', \text{ or } r + \Delta : r - \Delta :: \Delta : \Delta', \text{ hence}$$
$$\Delta'(r + \Delta) = \Delta(r - \Delta'),$$

therefore $2\Delta\,\Delta' = r(\Delta - \Delta')$ whence $\frac{1}{\Delta'} - \frac{1}{\Delta} = \frac{2}{r}$. Again the same proportion $\rho : \rho' :: \Delta : \Delta'$ may be written $\rho : \rho' :: \rho - r : r - \rho'$; hence $\rho(r - \rho') = \rho'(\rho - r)$ therefore $r(\rho + \rho') = 2\rho\rho'$ whence $\frac{1}{\rho} + \frac{1}{\rho'} = \frac{2}{r}$.

If we suppose $\rho = r$, we find $\rho' = r$, which shows that the foci are together at B, and as ρ increases, ρ' diminishes, until ρ becomes infinite, when $\rho' = \frac{r}{2}$, showing that a will then reach the principal focus F. Hence, in general, the principal foci move in contrary directions, and meet both at the centre and circumference. In the formula just given one of the conjugate foci lies between the principal focus and the surface of the speculum; while in the first set, one lay between that point (F) and the centre. A single formula, however, as the reader may verify, will include all cases, whether of concave or convex specula, or divergent or convergent pencils, provided we admit the use of negative quantities, and interpret the negative sign to mean that the distance affected by it must be measured in a direction contrary to that in the figure on which the formula was framed.

With respect to images, if A G be the object and g the focus conjugate to G, then $a\,g$ will be the image of A G; and conversely, if $a\,g$

be the object, A G will be the image, and their proportion may be easily calculated, for A G : $a g$: : C A : C a, that is, as $\rho : \rho'$, or as $\Delta : \Delta'$, which we have seen is the same ratio.

Example 4.—In the concave speculum of two-foot radius, an object is placed within 6 inches of its interior surface: how far will the image appear at the back of the speculum, and how much will it seem enlarged?

Here $r=2$, in feet, $\Delta'=\frac{1}{2}$, and since $\frac{1}{\Delta'}-\frac{1}{\Delta}=\frac{2}{r}$ we have $2-\frac{1}{\Delta}=1$, therefore $\Delta=1$, or the image will appear a foot behind the convex side and will be enlarged in linear dimensions as Δ to Δ', that is, as 2 to 1; in surface 4 : 1; in volume 8 to 1.

Example 5.—An object is placed 10 feet distance from a convex speculum of 3 feet radius; find the position and magnitude of its image.

Here $r=3$, $\Delta=10$, therefore $\frac{1}{\Delta'}-\frac{1}{10}=\frac{2}{3}$, whence $\frac{1}{\Delta'}=\frac{23}{30}$, therefore $\Delta'=1\frac{7}{23}$ feet, or 1 foot 3 inches, 8 parts nearly, at which distance in the concavity of the speculum the image will seem to be, and (in linear dimensions) Object : Image : : $\Delta : \Delta'$: : $10 : \frac{30}{23}$, that is as 23 : 3; the surfaces as 529 : 9, &c. Thus the reader with only a moderate knowledge of simple equations will be able to solve all questions relative to the images of objects formed by spherical specula, concave or convex. The images in the last two examples are erect. Generally the image will be erect or inverted according as one of the conjugate foci is between the principal focus and surface, or between that point and the centre; and this will include all cases, for it is easily seen that in every case one of the foci is in some part of the radius between the centre and surface.

In the preceding calculations, we have confined ourselves to such rays as fall nearly perpendicularly on the reflecting surfaces. The rays which are at a considerable distance from the axis of a spherical speculum are not reflected accurately to the same point as those incident near the axis; hence arises a diffusion of the reflected rays arising from the sphericity of the speculum and denominated the *spherical aberration*; and when measured *along* the axis, it is called the *longitudinal aberration*; but when perpendicular to it, through the focus, the *lateral aberration*. It will be sufficient in this article to calculate the amount of these aberrations in the most usual case when the incident rays are parallel, as those which proceed from the heavenly bodies.

Let S D represent a ray falling parallel to the axis C B; B D being the intermediate arc of the section of the speculum, D a the reflected ray; if this figure revolve round C B, it is evident that all rays incident on the annulus through which D moves will likewise be reflected to a, which is therefore strictly the focus of that annulus. Now F, the middle point of C B, is the point to which rays falling near the axis are reflected; hence a F is the longitudinal and F b the lateral aberration corresponding to the above annulus. To calculate the amount of these we may observe that the angle S D C (of incidence) is equal to C D a (of reflection), and also to D C a (by the theory of parallels); and since the angles a D C, a C D, are thus equal, therefore C a = a D. Let D T be a tangent at D, then a D T and a T D, being respectively the complements of a D C and a C D, are also equal, whence a T = a D, but also C a = a D, therefore a is the middle point of C T; and since F is the middle of C B, it follows that a F is the half of B T; thus the longitudinal aberration is known; and since the angle F $a b$ is the double of D C B, the lateral aberration is from thence known. Let the angle D C B $=\theta$, and radius C B $=r$, then C T $=r$ sec. θ and B T $=r$ (sec. $\theta-1$), hence we obtain the exact values of the two aberrations, namely, the longitudinal $=\frac{r}{2}$ (sec. $\theta-1$), and the lateral F$b=\frac{r \tan. 2\theta}{2}$ (sec. $\theta-1$). Hence in order that the aberrations may be inconsiderable, we ought to have the extreme magnitude of θ, namely, the angle B C d (in *fig.* 3), also small. On this supposition formulæ sufficiently approximate may be deduced from the above and better adapted for practice. For sec. θ put $1+\frac{\theta}{2}$, and for tan. 2θ put 2θ, which are respectively the approximate values; thence we get, longitudinal aberration$=\frac{r.\theta^2}{4}=\frac{\text{BD}^2}{4\,\text{BC}}$, and lateral aberration $=\frac{r.\theta^3}{2}=\frac{\text{BD}^3}{2\,\text{BC}^2}$, both of which are evidently very small, particularly the latter. The least circle of aberration is the smallest that would be formed on a card placed perpendicular to the axis near the focus F to receive the reflected rays; now if the intersection g of a reflected ray D g with the final one $d\,g$ be taken the most remote possible from the axis C B, it is evident that all the other reflected rays will pass between g and the axis, and hence the perpendicular distance from g to the axis is the radius of the circle of least aberration or diffusion. The question is thus reduced to one of maxima and minima, and may be easily solved in the usual manner by means of the Differential Calculus.

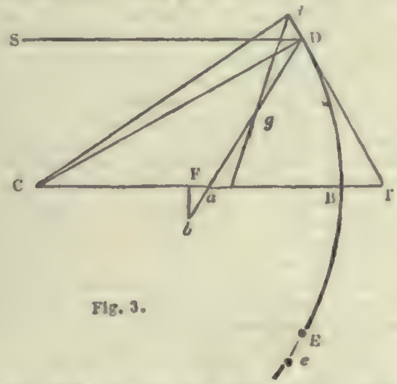

Fig. 3.

We have hitherto considered only such rays as fall nearly perpendicularly on the reflecting surface; but since rays fall at all incidences from a luminous point, each pencil of rays, at whatever incidence, when in a plane passing through the centre of the spherical reflecting surface, after reflection converges to or diverges from some point in that plane (unless reflected parallel); a line of light containing all such points in that plane forms a *caustic* line, and in all possible planes constitutes a caustic surface. Caustics formed by reflection have been distinguished from those produced by refraction by giving the name of diacaustics to the latter and catacaustics to the former, in the same manner in which that part of optics connected with refraction has been denominated dioptrics, and that with reflection catoptrics. In both cases the caustic line is the curve which each reflected or refracted ray *touches*: hence the equation to the caustic curve, whether produced by parallel, diverging, or converging rays, is easily obtained by taking the equation to one of the reflected or refracted rays, and then applying the differential calculus to find the curve touched by all such straight lines; namely, differentiate the equation to the reflected or refracted ray relatively to the constant in its equation, and then eliminate the constant between the two equations, which will then produce the equation to the caustic. In the general case of a system of rays no longer symmetrical about an axis we still have caustic surfaces, but the problem is then one of greater complexity. If the sun or a candle shine on a vessel containing liquid, and polished in the interior (such as a china cup of tea), a caustic line of light will be observable on the surface of the liquid, which line is a horizontal section of the caustic surface by that of the liquid.

We now come to the consideration of refracting transparent media; and if we suppose the constant ratio of the sine of incidence to that of refraction to be as m : 1, then m is called the index of refraction for the particular medium employed, the incident light being supposed to pass from vacuum. But if the light pass from the medium into vacuum, then the ratio of the sine of incidence to that of refraction will be as 1 : m, and $\frac{1}{m}$ will be the refractive index; m is evidently greater than unity, since the ray after entering the medium is turned towards the perpendicular, and $\frac{1}{m}$ is less than unity, because after the ray emerges from the medium into vacuum, it is turned from the perpendicular. If m be the index of refraction from vacuum into one medium which we may call A, and m' that from vacuum into a different medium B, then $\frac{m'}{m}$ is the index when the light passes from the medium A to B. [LIGHT.] A table of refractive indices is given in OPTICS, PRACTICAL.

Diverging rays fall from vacuum on the *plane* surface of a uniform and transparent medium: it is required to find the relation between the conjugate foci.

Let A be the focus of incident rays, D B E the surface of the medium, A B a perpendicular on D E, A G an incident ray near this perpendicular, G C (A G produced) the course of the ray if unrefracted, G c its actual course nearer to the perpendicular than G C, then c G to an eye placed in the medium will appear to proceed from the point a, the conjugate focus; the question is to determine the relative situations of a and A.

Let A B $=\Delta$, a B $=\Delta'$, and m be the index of refraction; then B A G, the complement of A G B, is equal to the angle of incidence, and B a G to that of refraction. Let these angles be respectively denoted by I and R, and B G $=k$; then $k=\Delta$ tan. I, and also to Δ' tan. R, therefore $\frac{\Delta'}{\Delta}=\frac{\tan. \text{I}}{\tan. \text{R}}=\frac{\sin. \text{I}}{\sin. \text{R}}\cdot\frac{\cos. \text{R}}{\cos. \text{I}}=m.\frac{\cos. \text{R}}{\cos. \text{I}}$; but when G is very near B, the angles I and R are exceedingly small, and their cosines may be taken as units, in which case $\frac{\Delta'}{\Delta}=m$, therefore $\Delta'=m\Delta$; and since m is greater than unity, Δ' is greater than Δ in the ratio of m : 1. Conversely, if a ray from a medium bounded by a plane surface pass into vacuum,

$\frac{1}{m}$ is then the index of refraction, and we should have $\Delta' = \frac{1}{m} . \Delta$, in which case Δ' is less than Δ. This explains why the bottom of a clear river seems nearer to the surface than it really is by about one-fourth of its true depth.

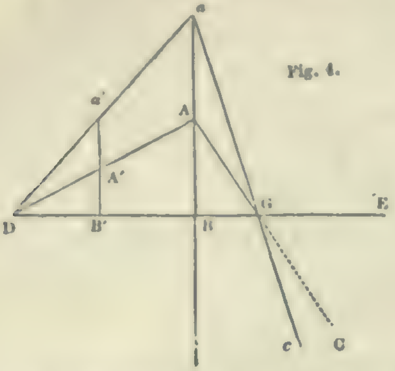

Fig. 4.

The image of a straight line in vacuo seen from such a medium will be another straight line; for let A A′ be such a line, produce it to D, and join D a, then since a' B′ : A′ B′ : a B : A B : : m : 1; therefore a' is the focus conjugate to A′, and consequently $a\,a'$ is the image of A A′. It must however be observed that A A′ must be of small dimensions, in order that the rays reaching the observer's eye may be considered as nearly perpendicular to D E, otherwise the above proportion would require to be modified, and the image would be curved. In the above case the image $a\,a'$ is more remote from the surface D E than the object; but the contrary happens when the object is in the medium, when the image will be nearer the surface than the object is. Hence many familiar optical phenomena may be understood. Thus, when a straight stick is partly immersed in water, the image of the immersed part being raised nearer to the surface than the true object, will cause the stick to appear bent or broken, as well as shorter than it really is; but when immersed perpendicularly to the surface, the stick appears to be only contracted about one-fourth of the part immersed, for the image and object are then in one straight line.

As refracting media bounded by a single curved surface rarely if ever can occur in practice, we shall proceed to consider lenses, particularly the double convex lens, as known most generally. For their various species and for further details see LENS.

Let D B E B′ represent a plane section of a double convex lens, that plane including the centres C C′ of the bounding surfaces D B E and D B′ E; let A (in the *axis* C C′) be the focus of incident, and a of the emergent rays. Let m be the index of refraction for incident, and therefore $\frac{1}{m}$ for emergent rays; and let A G K a represent the track of a ray near the axis; let C B $= r$; C′ B′ $= r'$, A B $= \Delta$, a B′ $= \Delta$, and the thickness B B′ $= t$, we have to determine the relation existing between these quantities. First we have sin A G $c = m$ sin K G c, let G A C $= \theta$, G C A $= \alpha$, and the inclination of K G to the axis be ϕ; while δ is the distance of the point at which G K cuts the axis from B; then the above equation is the same as $\sin(\theta + \alpha) = m \sin(\phi + \alpha)$, from which by trigonometry we deduce $\frac{\sin\theta - m\sin\phi}{\sin\alpha} = \frac{m\cos\phi - \cos\theta}{\cos\alpha}$. Now $\frac{\sin\theta}{\sin\alpha} = \frac{\text{C G}}{\text{A G}}$, of which the ultimate value, when G is at B, is $\frac{\text{C B}}{\text{A B}} = \frac{r}{\Delta}$, for the same reason the ultimate value of $\frac{\sin\phi}{\sin\alpha}$ is $\frac{r}{\delta}$, and the ultimate values of $\cos\theta$, $\cos\phi$ and $\cos\alpha$, are each unity; therefore we get $\frac{r}{\Delta} - \frac{mr}{\delta} = m - 1$, or $\frac{1}{\Delta} - \frac{m}{\delta} = \frac{m-1}{r}$; hence δ, which determines the focus of the first set of refracted rays, is known; and therefore also $\delta + t$, which is its distance from the second surface. Now, since the ray would traverse the same course if we supposed it to commence at a, and proceed through a K G to A, it follows in the same way that $\frac{1}{\Delta'} + \frac{m}{\delta + t} = \frac{m-1}{r'}$, from whence Δ' is known.

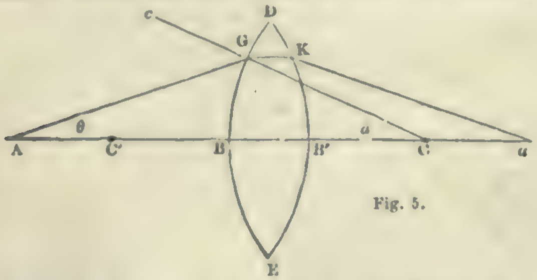

Fig. 5.

If we neglect t as being small, we may eliminate $\frac{m}{\delta}$, and thence obtain $\frac{1}{\Delta'} + \frac{1}{\Delta} = (m-1)\left(\frac{1}{r'} + \frac{1}{r}\right)$; the spherical aberrations may be found by a similar process to that we have employed for reflection, and the inverse or erect positions of the images ascertained by the like method.

When we have one side plane, we have only to suppose r infinite, and when concave to suppose r negative, and thus one general formula, by proper attention to the signs, may be made to apply to all forms of lenses.

There is a cause of aberrration for refracted light, which does not exist for reflected rays, and it is of more consequence in deforming and colouring images than all the effects of spherical aberration. The chromatic dispersion [DISPERSION] arises from the fact that all the coloured rays which compose solar or other light have different refractive indices for one and the same refracting medium; hence the prismatic spectrum, which only consists of successive circular images of the sun, of the different colours of the rays, overlapping each other. This aberration has, by the successive labours of Dollond, Fraunhofer, and others, been successfully combated. [OPTICS, PRACTICAL.]

The possibility of correcting the aberration arising from the unequal refrangibility of rays of light in the refracting telescope, by means of a compound object-glass, permits the employment of object-glasses of a much larger diameter, in comparison with their focal length, than could otherwise have been tolerated. Now for a lens of given focal length, the spherical aberration increases rapidly with the aperture. It becomes therefore of importance to correct as far as possible this aberration by giving appropriate forms to the surfaces, or by combining together two or more lenses.

Writers on optics show that a curve-line by whose revolution about an axis there shall be described a surface which, being that of a refracting medium, will cause all rays incident upon it, when they diverge from or converge to one point, to be refracted so as to converge to or diverge from one point is, in its most general form, of the fourth order: but when the radiant point is at an infinite distance from the refracting surface, as when it is at a celestial body, the form of the surface, supposing the density of the refracting medium to be greater than that of the medium which surrounds it and in which are the incident rays, is proved to be that of a spheroid: and rays falling on its convexity, parallel to the major axis of the spheroid, would, within the medium, converge accurately to the focus most remote from the place of incidence. If the refracting medium were less dense than that in which are the incident rays, the surface would be that of an hyperboloid. The semi-transverse axis both of the spheroid and hyperboloid must be, to the excentricity, as the sign of the angle of incidence is to the sign of the angle of refraction: in the former case the refraction is from the surrounding medium into the spheroid; and in the latter, from the concave surface of the hyperboloid into the surrounding medium. It follows therefore that if a meniscus lens denser than the surrounding medium have its anterior surface spheroidal, and its posterior surface that of a sphere whose centre is at the further focus of the spheroid; since the rays will then suffer no refraction in passing through the posterior surface, it will be aplanatic. Also if the anterior surface of a medium be plane, so that the parallel rays incident perpendicularly on it may suffer no refraction in entering, and the other surface be part of a hyperboloid, the medium between the surface being denser than that which surrounds it, the plane lens thus formed will be aplanatic; the refracted rays converging to the opposite focus of the hyperbola.

The form of the expression for aberration, when parallel rays are incident on a lens of moderate aperture having spherical surfaces, is such that the aberration cannot be made to vanish with any real values of the radii of those surfaces unless the index of refraction in the medium be equal to or less than 0·25. But there is in nature no medium which has such a refractive index, therefore, failing in making spherical lenses strictly aplanatic, and it having been found impossible, hitherto, to form them with surfaces produced by the revolutions of conic sections, mathematicians have investigated expressions for the form under which, with a given refractive index, the aberration of the focus shall be a minimum; see the article "Light" in the 'Encyclopædia Metropolitana' (art. 305), where the ratio between the radii of the surfaces, in this state, is given. From that ratio it is shown that, when the index of refraction is 1·5 the lens should be of the double convex form, having the radius of the posterior surface six times as long as that of the anterior surface, or that which is nearest to the radiant point.

But although the spherical aberration for a pencil of parallel rays cannot be made to vanish in a single lens bounded by spherical surfaces, the compound lens employed in an achromatic object glass, designed in the first instance to correct the chromatic aberration, has the further advantage of enabling us to render insensible the spherical aberration. Such a lens presents us with four spherical surfaces, the three independent ratios between the radii of which enable us to satisfy three conditions, while the scale of the system is determined by the focal length of the combination. The most important condition to satisfy is, that the chromatic aberration shall be corrected; and if we further assume that the spherical aberration (or rather its leading term) shall vanish, we shall still have one relation between the four radii remaining disposable, whereby some further advantage may be secured, provided it be not incompatible with those already assumed, which will be known by its leading, when the condition of it is expressed analytically, to an equation having only impossible roots. Clairaut introduced the condition that the adjacent surfaces should have the same radii, one surface being convex and the other concave, so that the lenses would be everywhere in contact, and might be cemented together. Instead of this, Sir J. Herschel proposes to introduce the condition that the lens shall be aplanatic for pencils, not only of parallel, but also of slightly divergent rays. In the treatise on light above quoted (arts. 468-473), he has pointed out certain advantages of this method, and has computed with different dispersive ratios a table of the radii of the lenses for the compound object-glass of a telescope constructed according to this system as nearly aplanatic as possible, the compound focal length being 10·000; and, by the proportions indicated, the radii for object-glasses of any other compound focal length may be found. (On the subject of aplanatic lenses for microscopes, see Microscope.)

It may be well here to make a few remarks about the eye, regarded merely as an optical instrument, its general structure and functions being very fully described under the article Eye, in the Nat. Hist. Div. In this point of view its general office resembles that of a telescope in having to form images of distant, or moderately distant objects at its focus, which in order that the vision may be distinct must coincide with the retina. It differs, however, from a telescope, in having the whole space between the place of the first refraction and that of the focus filled with dense matter, in not having the refraction at the several surfaces centrical, and in having a much larger aperture, in comparison with the focal length, than could be tolerated in the best telescope.

On account of the magnitude of this aperture, the effect of spherical aberration might be seriously inconvenient if the media of which the eye is composed were severally homogeneous and bounded by spherical surfaces. The defects of spherical aberration, it should be remembered, increase very rapidly with the aperture of a telescope, more rapidly than those of chromatic aberration. It is at the surface of the cornea that the main refraction takes place, and the protuberant form of this part of the eye seems calculated to diminish the aberration; for we have seen that a prolate spheroid of suitable excentricity refracts accurately to a point a pencil of rays incident parallel to its axis. The increasing density of the crystalline lens in passing from its exterior to its centre has a similar tendency, since an ordinary glass lens fails to refract a pencil of parallel rays accurately to a point in consequence of the over refraction of the marginal rays compared with those incident towards the middle.

No compensation for the chromatic aberration of direct pencils seems to exist, or to be required. If a pure spectrum be thrown on a page of small print, and the page be viewed by a person of ordinary sight at the ordinary distance of reading, the print will be seen very distinctly about the bright part of the spectrum, but somewhat indistinctly from long-sightedness in the red, and very indistinctly from short-sightedness in the violet. Again, if the sun or a candle be viewed through several pieces of cobalt blue glass superposed, a combination which transmits only the extreme red, and the blue and violet of the spectrum, the red image and the blue image, though superposed, will not be seen in focus together. But in ordinary vision, where all the colours of the spectrum are viewed together, the confusion arising from the imperfect focusing of the fainter extremities of the spectrum is insensible.

If the eye were perfectly invariable in form, the images of objects at different distances could not all be formed *on* the retina, and therefore, such objects could not all be seen distinctly. The eye, however, possesses a power of adaptation, answering to the focusing of a telescope, which accompanies involuntarily the voluntary act of making the axes of the two eyes converge towards a nearer or more distant object by *looking at* the object.

If the cornea be too protuberant, the rays will be brought to a focus before reaching the retina (unless they come from an object close at hand), and the vision will be indistinct. A person thus affected is said to be *short-sighted*. If the cornea be too flat, the rays will reach the retina before they come to a focus (unless they come from a very distant object, and perhaps not even then), and the vision will again be indistinct, such a person being said to be *long-sighted*. These defects, as is well known, may be corrected by the use of spectacles, respectively concave and convex, and of suitable power. But there is another defect, consisting in the length of sight being different in different planes, which is far from uncommon, which cannot be corrected by ordinary lenses, though it may by a properly chosen lens having one or both surfaces cylindrical. [Lens.]

OPTICS, PRACTICAL, is that part of science which applies the physical properties of Light and the mathematical laws of Optics to the construction of useful optical instruments. By the former we determine the constants necessary to render the formulæ of the latter convertible into numbers. The refractive and dispersive indices peculiar to transparent media are constants of this nature, and the instruments adapted to the easy vision of near or distant objects, to great or small objects, and to other optical purposes, are, according to the plan of this work, described under their proper heads. [Camera Lucida; Heliostat; Microscope; Telescope; &c.]

The refractive indices of transparent and semi-transparent media have been a subject of research to many experimenters, and were considerably advanced by Newton. (Newton's 'Optics.') The additional properties of light discovered since his time have enabled philosophers to calculate to a far greater degree of accuracy the indices both of refraction and dispersion than was then practicable.

The theory of achromatism, or the method of correcting the aberrations of the rays of light, has been pursued by Euler, D'Alembert, Herschel (Sir J.), and many others; but the earliest successful construction was made by Mr. Hall, in 1733. The same was effected in 1757 by Dollond, whose labours, together with that of his son, gave a great impulse towards the complete accomplishment of an object of which Newton seems almost to have despaired. In the same career of late years we must distinguish Fraunhofer, of Benediktbeuern, in Bavaria, who obtained at an early age from the French Academy the prize for the actual construction of achromatic glasses. Not only were the necessary manual operations conducted by himself with patience and the minutest attention to all the practical details of the quality of his glasses and the accuracy of grinding and polishing, but he had also the merit and advantage of observing the dark lines which cross the prismatic spectrum, and which are of the greatest utility in determining the indices above alluded to. From the nature of the composition of the glasses, some of his finest telescopes have of late become considerably tarnished, particularly those in exposed situations. This could not have been easily foreseen, and many of his telescopes remain still in good condition.

The first account of Fraunhofer's remarkable optical discoveries is given in a paper which he published in the 'Memoirs of the Academy of Bavaria' for 1814–15. By means of a theodolite furnished with a telescope, he measured the distances of the principal lines; and by applying a photometer to the different coloured rays, he drew a curve, the ordinates of which express the illuminating powers of the several rays. To these researches he soon afterwards added some beautiful experiments on the diffraction of light, an account of which he published at Munich, and they also appeared in an abridged form in the 'Bibliothèque Universelle,' January, 1822. It is believed that his close application to those and similar researches accelerated his death, which followed soon after.

The accurate determination of the refractive and dispersive indices has also been pursued with great success in this country, and simultaneously by some of the following distinguished men:—Dr. Thomas Young, Dr. Brewster, Dr. Wollaston, Sir. J. Herschel, Prof. Faraday, Prof. Powell, &c.; and in France, by Biot, Dulong, &c.; some of the results of whose experiments, in a very compressed form, are given in the two following tables:—

Refractive Indices.

Hydrogen	1·00014	Glass—English plate	1·500
Oxygen	1·00027	Dutch	1·514
Air (atmospheric)	1·00029	Fraunhofer's crown (No. 13) ray E	1·533
Nitrogen	1·0003	Rock crystal	1·568 to 1·575
Aqueous humour of eye	1·337	Amber	1·547
Vitreous	1·336	Ruby red glass	1·601
Salt-water	1·343	Sulphur	1·958
Albumen	1·360	Glass of antimony	2·000
Crystalline lens of eye	1·378	Diamond (S. G. = 3·4)	2·439
Oil of almonds	1·470		
Oil of turpentine	1·475		
Camphor	1·500		

Dispersive Powers.

Chrom. lead	0·400	Oil of turpentine	0·043
Oil of cassia	0·139	Amber	0·041
Green glass	0·061	Gum Arabic	0·036
Flint glass	0·052	Oil of cloves	0·062
		Sulphate of lead	0·060

OPTO'METER (from *ὄπτομαι*, to see, and *μέτρον*, a measure) is an instrument for ascertaining with precision the refractive powers of lenses, and the distances at which minute objects may be distinctly seen. The idea originated with Scheiner; but such an instrument was constructed by Dr. Porterfield, and was improved by Dr. Thomas Young. It consisted of a slip of ivory, unpolished, or of wood covered with white paper, about eight inches long and half an inch broad, on which, in the direction of its length, was drawn a narrow and well-defined black line. At one extremity of the slip was fixed a plate of ivory, or a piece of card, nearly perpendicular to its length, and this was perforated either with a single aperture or with two apertures at distances from one another varying from $\frac{1}{40}$th to $\frac{1}{10}$th of an inch, but not exceeding the diameter of the pupil of the eye. On applying the eye to a single aperture, and looking in the direction of the line, drawn on the instrument, the line appears to have a certain breadth, and to be ill defined, at the nearest extremity: the breadth gradually diminishes at points successively more remote till it becomes a minimum, when the line becomes distinct; beyond that point the line gradually increases in breadth, becoming again ill defined. On applying the eye to a double aperture, the line appears to be double, the parts seeming to cross one another at a very acute angle, and the intersection is at the place where a single line would have had the minimum breadth:

beyond this intersection the two lines appear to diverge from one another, and to become indistinct. The point of intersection is that at which a minute object being placed, its image would be distinctly seen by the eye at the aperture, and its distance from the eye may be immediately found by means of a scale of inches on the instrument, a sliding index being, at the time of making the observation, moved to the point of intersection.

This distance affords, evidently, a measure of the refractive power of the observer's eye; since rays of light diverging from a small object at that distance are, by the lenses of the organ, made to converge accurately to a point on the retina, so as to form there a single and well defined image. If the object were either brought nearer to or removed farther from the eye, the rays, after passing through the two apertures, would form two images, both of which would appear to be less perfectly defined than the single image.

It being assumed that a person whose sight is perfect sees a small object distinctly at the distance of 8 inches from the eye, Dr. Young obtained by computation a series of numbers which he placed on the scale of the optometer, at such distances from the plate containing the apertures, that a spectator having a *presbyopic* eye (or one which, like those of most persons who are advanced in life, has distinct vision of small objects only when they are at greater distances than 8 inches) on looking through the slits and observing the place where the two images of the line cross each other, might ascertain at once, by the number at the place, the focal length of a convex lens which would enable him to see distinctly at 8 inches. He also computed a series of numbers which he placed on the scale in such situations that a person having a *myopic* eye, or one which has distinct vision of objects at less than that distance from it, on observing the place at which the lines appeared to intersect one another, might ascertain the virtual focus of a concave lens which would enable him to see distinctly at 8 inches. The optometer thus became a means of enabling persons to make choice of the proper lenses for spectacles which would correct the imperfections of their natural vision.

But the scale of Dr. Young's optometer being, for convenience, only 8 inches long, and the inferior limit of distinct vision in a presbyopic eye being beyond that distance, Dr. Young applied to his instrument a convex lens of 4 inches focus, by which the point of distinct vision for such an eye was reduced within 8 inches from it: the numbers on his scale were therefore computed for the instrument when furnished with such a lens.

Dr. Young used the optometer for the purpose of determining the refractive powers of the eye, not only in its usual state, but also when, in cases of cataract, the crystalline lens had been displaced or extracted, and when the effect of the cornea had been rendered null by immersing the anterior part of the eye in water, which was contained in a cell of a proper form, and having a plane glass in front. By such means he endeavoured to ascertain in what manner the eye accommodates itself to distinct vision for objects at different distances from it; and his conclusion is that the faculty depends entirely upon changes of figure which take place in the crystalline lens. (*Lectures on Natural Philosophy*, vol. ii.)

ORA. [MONEY.]

ORACLE (from the Latin *oraculum*, and that from *os*, *or-is*, a mouth). Oracle was the Roman name used to denote the place where answers were supposed to be given by any of the divinities to those who consulted them respecting the future. Sometimes also it was used to signify the response which was delivered, and sometimes the deity from whom this response was imagined to proceed. Its primary and proper signification indeed is that of a response. Cicero ('Topic.,' 20) says that oracula were so called "quod inest in his Deorum Oratio." Those who were sent to consult them were sometimes called *oratores*. (Livy, v. 15.) Oracular responses were called *chresmi* (χρησμοί) or *manteia* (μαντεῖα) by the Greeks; the name *manteion* (μαντεῖον) was also often given to the oracular place, or the seat of the oracle.

Curiosity regarding futurity, and the desire to penetrate its mysteries, are dispositions which exert a powerful control over the minds of men in every stage of society; among nations that have made little advancement in civilisation and intelligence, they operate with peculiar force; and in these dispositions, combined with the belief that the gods had both the ability and the inclination to afford the knowledge so eagerly longed after, the oracles of the pagan world had their origin. Of these oracles the most famous were those of Greece, and among them that which had claims to the highest antiquity was the oracle of Zeus at Dodona. [DODONA, in GEOG. DIV.] But the most celebrated of the Grecian oracles was that of Apollo, at Delphi, a city built on the slopes of Parnassus in Phocis. [DELPHI, in GEOG. DIV.] Besides the oracles of Zeus and Apollo at Dodona and Delphi, that of Trophonius, near Lebadeia in Bœotia, may be mentioned, as having been held in high estimation. There were many other oracles in Greece, but of less repute.

Among the other most noted oracles of antiquity were that of Zeus Ammon in the desert of Libya, that of the Branchidæ in Ionia, of Pella in Macedonia, of Sinope in Paphlagonia, of the head of Orpheus at Lesbos, &c. Most of the heathen deities, and even the demigods and heroes, had oracles of their own. There were also current in Greece numerous so-called prophecies, the productions of individuals who were probably supposed to speak under a divine influence. Such were those of Bacis and Musæus, in which the battle of Salamis was predicted, and that of Lysistratus, an Athenian. (Herod., viii. 96.) But those productions are perhaps more appropriately considered under the head of PROPHECY, though Herodotus applies to them the same name (χρησμὸς) as to the responses from Delphi and other oracular places. As to the Sibylline oracles, see SIBYL.

Though the Romans had various modes of ascertaining the will of the deities, it does not appear that oracles like those of Delphi or Dodona were ever established among them; and we find that the oracles of Greece, and particularly the far-famed oracle of Delphi, were consulted by them on many important occasions. (Livy, v. 15; xxii. 57, &c.)

Among the Jews, the Urim and Thummim, which by an extraordinary brightness made known the will of Jehovah, bore a striking resemblance to the heathen oracles; and the oracle of Batheol, or *daughter of the voice*, which was originated after the death of Malachi, was completely identical with them.

The modes in which oracular responses were delivered were very various. At Dodona they issued from the hollow of an oak; at Delphi they were delivered by the Pythia; and at the oracle of Ammon they were pronounced by the priests. At Memphis a favourable or unfavourable answer was understood to be returned, according as Apis received or rejected what was presented to him. [APIS.] Sometimes the reply was given by letter; and sometimes the required information could be obtained only by casting lots—the lots being dice with certain characters engraved on them, the meaning of which was ascertained by referring to an explanatory table. Dreams, visions, and preternatural voices also announced the will of the divinities.

The importance attached by the Greeks and Romans to oracular responses is a striking feature in the history of those people. Hardly any enterprise, whether public or private, of any moment, was undertaken without recourse being had to them and their sanction being obtained. In later times, indeed, their influence was greatly diminished, and thus gradually fell into disrepute. Cicero affirms that long before his age even the Delphic oracle was regarded by many with contempt; and there is little doubt that oracles were considered by philosophers as nothing different from what they really were, and by politicians as instruments which could be used for their purposes. The reply of Cato to Labienus, who wished him after the battle of Pharsalia to consult the oracle of Jupiter Ammon, embodies the opinion of that eminent Stoic respecting the propriety of thus questioning the gods. "On what account, Labienus, would you have me consult Jupiter? Should I ask him whether it would be better to lose life than liberty? Whether life be a real good? We have within us, Labienus, an oracle that can answer all these questions. Nothing happens but by the order of God. Let us not require of him to repeat to us what he has sufficiently engraved on our hearts. Truth has not withdrawn into these deserts; it is not engraven on the sands of Libya. . . . . Let the inconstant and those that are subject to waver according to events have recourse to oracles. For my part, I find in nature everything that can inspire the most constant resolution. The coward, as well as the brave, cannot escape death. Jupiter can tell us no more." (Lucan, 'Pharsalia,' lib. ix., v. 566–584.)

The question has been gravely discussed, whether oracular responses ought to be ascribed to mere human ingenuity and wisdom, or to diabolical agency. Most of the Christian fathers maintained that they ought to be ascribed to the latter. Allusion is made to this opinion in the first book of 'Paradise Lost,' where the spirits of Pandemonium are described as having taken possession of the various idols of the heathen world. There is nothing, however, in the history of the ancient oracles to countenance such a notion, or to lead to the belief that a supernatural cunning and skill directed them. Their replies to those who consulted them were for the most part obscurely and equivocally expressed, and so as to admit of different explanations, according as the wishes of the inquirer might suggest or the event determine; and even in those instances where trial was designedly made of the reality of their pretensions, it is not difficult to account for the success with which they stood the test, without calling in the assistance of demoniacal instrumentality.

Another circumstance respecting the oracles, which has given birth to much controversy, is, the time when they ceased altogether to give responses. Eusebius was the first who propounded the opinion that they became silent ever after the birth of Christ, and many writers, willing thus to do honour to the author of Christianity, have given it their support. Milton makes allusion to this theory also in the most magnificent of all his minor poems, 'The Hymn of the Nativity;' and in lines of solemn and elevated beauty, of which the following are the commencement, pictures the consternation of the heathen idols at the advent of the Saviour:—

"The oracles are dumb,
No voice or hideous hum
  Rings through the arched roof in words deceiving.
Apollo from his shrine
Can no more divine,
  With hollow shriek the steep of Delphos leaving.
No nightly trance or breathed spell
Inspires the pale-eyed priest from the prophetic cell."

But the circumstance that may thus be made available for the purposes of poetical ornament, happens unfortunately to be contrary to fact. It appears from the edicts of the emperors Theodosius, Gratian, and Valentinian, that oracles existed, and were occasionally at least consulted, till so late as A.D. 358. About that period they entirely ceased, though for several centuries previous they had sunk very low in public esteem. So few resorted to them, that it was no longer a matter of interest to maintain them. Towards this consummation Christianity powerfully contributed, by the superior enlightenment which it carried along with it wherever it was introduced, and by the display which it made of the falsehood and folly of the superstitions which it was destined to overthrow.

ORANGE. In the article CITRUS, in NAT. HIST. DIV., the different species of this genus have been described, as well as the more remarkable varieties of the orange. Being a native of warm southern latitudes, the orange is a remarkable instance of a fruit which gives employment and forms even an article of commerce from the southern to the more northern European nations. Thus, it is exported from Italy and Malta, as well as from the south of Spain and from Portugal, but in very large quantities from the Azores. Its cultivation is profitable not only on account of the esteem in which the fruit is held, but also from the extreme prolificness of the tree, so that the fruit is sold even in England at a price not much above and sometimes even for less than our own apples and pears.

Oranges are imported, as well as lemons, packed in boxes, and wrapped up separately in paper. The entries for home consumption, in 1859, amounted to 984,901 bushels.

The citron is considered to have been first cultivated in Italy by Palladius, in the 2nd century, but the orange not until the 14th century; it is probable, from the name, that it was introduced by the Arabs into Spain. Oranges bear the open air also at Nice, Genoa, and Naples, but at Florence and Milan, and often at Rome, they require the temporary protection of a shed. They are usually planted in boxes, and removed from the conservatory into the open air in summer, in France as well as in England; but since the introduction of the great variety of flowers from all countries, orangeries and fine specimens of orange and citron trees have been less in fashion, though none are more desirable on account of the combination of elegant verdure, the grateful odour of the flowers, and the rich appearance of the fruit. They have been cultivated in England since 1492: and Mr. Loudon states that at the Wilderness, Kent, there are three trees in boxes, not surpassed by any trees so grown in Europe; and that at Saltcombe, in Devonshire, there are in a few gardens orange-trees which have withstood the winter in the open air for upwards of a hundred years. They are propagated either by seeds, by cuttings, by layers, by grafting, or inoculation; and the orange thrives best when grafted on the lemon. The plants grown from seeds require so long to come to perfection, that they are seldom so propagated in England. The most regular and garden-like culture is in the orange orchards at Nervi, Monaco, and other places in the neighbourhood of Genoa. At the former are the orange nurseries which may be said to supply all Europe with trees, though the cultivation is of a very indifferent character, but the fine climate, strong clayey soil, and abundant manurings supply the place of more skilful treatment. Budding and grafting are performed in England at the usual season for such operations, but they may be performed at any time when the sap is in motion. In budding Mr. MacIntosh recommends that the cross cut should be made at the bottom of the slit in the bark instead of the top. Mr. Henderson, of Woodhall, one of the most successful growers of the Citrus tribe, has given a full description of the practices he adopts ('Caled. Hort. Mem.,' iii.; and Loudon's 'Encycl. of Gardening'); he considers cuttings as the quickest mode of getting plants. At Genoa and Florence the trees are grown in a strong yellow clay which is richly manured. The French, in preparing a compost, compensate for quantity by richness of manure. Henderson takes one part of light brown mould from a piece of ground that has not been cropped or manured for many years, one part of peat earth such as is used for growing heath, two parts of river-sand, or pit-sand, if it be free from mineral substances, and one part of rotted hot-bed dung, with one part of rotted leaves of trees, and mixes them all well together, so as to form a compact soil of uniform quality. The blood of animals is found to be valuable as a manure, and is improved by being mixed with mineral superphosphate of lime. Charcoal, not too finely broken, adds much to the health of the tree when mixed with the soil.

Orange-trees grow exceedingly well in pots and boxes, but they should be raised from the floor and well drained. The temperature of the soil required for producing fruit in perfection, is from a maximum of 85° to a minimum of 58°. In England the soil seldom reaches 66°, and often sinks to 36°; therefore, except in forcing-houses nothing can be expected from the plant but its flowers, the fruit if formed being small and tasteless. Yet the tree is hardy, and will live through an English winter if kept in the dark and dry. After the flowering, instead of allowing the wood to grow, continental gardeners clip them round into perfect globes with the hedge-shears. To use the knife would be better, but the practice is right; it rids the trees of superfluous matters, insures the maturing of the buds on the short branches left, the sap is thrown back into the buds, and thus elaborated into perfect flower-buds for the ensuing season. Trees so treated, and kept pretty dry from November till March, remain perfectly safe under an opaque roof. With us, the growing season is not favourable enough to ripen the wood without the aid of covering; and that, to insure health and abundance of bloom (the only thing to be sought for), must be transparent. These remarks apply to the lemon as well as to the orange.

Mr. St. John ('Travels in the Valley of the Nile') says, he saw a tree produced by joining the seed of the citron, the orange, and the lemon. The external coating being removed from one, this was placed between the other two, from which the coating of one side only had been removed. They were then bound together with a fine grass and planted; the result was a fruit combining beneath one rind, but distinctly marked both internally and externally, the qualities of the three species of which the seeds had been used.

(See the work of Risso of Nice, and Poiteaux of Versailles, *Histoire Naturelle des Oranges*, where 169 sorts are described, and 105 of them figured; also that of Gallezio, *Traité du genus Citrus*, who has given an account of the 40 different kinds cultivated in Italy; and Mr. Loudon's *Encycl. of Gardening*.)

ORANGE, LEMON, LIME—*Medical Properties of.* These are all species of the genus *Citrus*. Save the root, wood, and bark, every one of them yields from every part something of use in medicine or perfumery. *Citrus aurantium*, or sweet orange, is too well known to require description. Its leaves and unripe berries yield by distillation a fragrant oil called *essence de petit grain*. The small green unripe fruits of this species, and also of the *Citrus bigaradia*, or bitter orange, have an aromatic odour and bitter taste, and are used to flavour curaçoa. "When smoothed by a lathe, they form the issue peas of the shops." The flowers of the sweet, but still more the bitter, orange are distilled to yield orange-flower water, termed *aqua Naphae*. This contains free acetic acid; this acid acts upon the lead in the joining of the stills in which it is prepared, or the leaden vessels in which it is imported; so that orange-flower water often contains a notable quantity of acetate or sugar of lead, giving rise to some troublesome decompositions when iodine or several other matters are mixed with it, as first pointed out by Mr. Squire. It is directed to be tested with hydrosulphuric acid, to ascertain its freedom from this contamination. Oil of orange-flowers, called *oleum Neroli*, is obtained by distillation of the flowers of the sweet and still more of the bitter orange. An inferior sort is got by expression of the grated rind.

The *Citrus medica*, or citron, yields two volatile oils, one termed essence or essential oil of citron, the other essence or essential oil of cedrat. This must not be confounded with cedrat, which is a liqueur or compound of the distilled oil of lemons and simple syrup. Neither must it be confounded with citronelle, or *eau de Barbades*, which is a West Indian distilled spirit of orange, lemon-peel, and aromatics, with proof spirit. *Crême des Barbades* is similar, prepared with rum. *Citronella Zeylanica*, or oil of lemon-grass, from Ceylon and the Moluccas, is obtained from the *Andropogon citratum*, a grass, not of the orange tribe. *Citrus bergamia* yields from the rind of the fruit, by either expression or distillation, the well-known essence or volatile oil of bergamot. This name is also applied to a volatile oil obtained from a mint, the *Mentha citrata* (or *M. odorata* of Sole, in his work on 'British Mints'), called bergamot mint. The volatile oil of the genuine bergamot is said by Liebig to differ, by containing oxygen, from the other oils of this genus, which are mere carburets of hydrogen. This similarity of chemical composition renders it difficult to distinguish mint oil from that of bergamot; but in all probability there is a difference in their polarising power or tendencies.

As stimulants, carminatives, and antispasmodics, these oils are occasionally used pure, on sugar, but mostly as constituents of tinctures and mixtures. Many of them enter into the composition of eau de Cologne, where ammonia seems the chief solvent. The pure oil of the lemon, either spirted or carefully dropped into the eye, has been used with benefit in chronic inflammation of that organ, whether of rheumatic or scrofulous origin, particularly where there is a tendency to the formation of specks of the cornea. It acts like the *Vinum opii*.

The fresh rind of the sweet orange, rasped, and pounded with three times its weight of loaf sugar till well incorporated, constitutes the *confectio aurantii* of the Pharmacopœia. The rind of the sweet, more frequently of the bitter, orange, occasionally of the citron, and even the lemon, is made into a conserve by having the pulp scooped out, then boiled, and boiled sugar poured over the rind.

The rind or peel of the sweet, but more frequently of the bitter, orange, and also the citron, are frequently candied and used at dessert, or the last in rich puddings, buns (Scotch), and short-bread. The rind or peel of the bitter orange, from which the soft, white, downy inside lining has been carefully stripped off, constitutes what is termed *Flavedo aurantii*, a wholesome stomachic. The bitter orange, termed Seville, is made in Scotland into a conserve called marmalade. The whole of the fruit, except the pips and inside lining (termed doff) of the peel, is used for this purpose, being boiled till the fruit is made quite tender; the skin is then to be cut into fine shreds (the finer the better, or rasped), and the whole boiled till it jellies. The flavour is greatly improved by using a few of the more fragrant-skinned sweet oranges along with the bitter. When properly prepared, this forms one of the most wholesome conserves at breakfast or dessert.

The skin of the sweet orange in the crude state is indigestible, and even dangerous. Children should be prevented eating it or swallowing the pips, as even fatal results have followed eating the rind of one orange. The pulp of the sweet orange, and, still better, the expressed juice, is very grateful to persons with feverish or inflammatory diseases. Orangeade is made by adding water and sugar to the juice. The adjunct of sugar is objectionable. Greatly more objectionable is sugar with lemon-juice, which is much more digestible when pure or diluted with water only. The utility of lemon-juice in exalting the digestive powers of the stomach was long familiarly known to gourmands, and taken by them as an accompaniment of young and fat meats, such as veal, lamb, pork, goose, and other food. These are almost all *white* meats; but in French cookery lemon-juice is taken with black meats, such as game. Ducks of different kinds are seasoned by the English with lemon-juice. It was, however, long before the observation of its power in these instances led to its employment to raise the depressed condition of the stomach among seamen and others compelled to use salted, hard, and innutritious meat for a length of time. To Sir Gilbert Blane is due the merit of this great improvement, which has almost entirely banished sea-scurvy from our navy. [Antiscorbutics.] But many medicines have their curative power increased by the accompaniment of lemon-juice. Bilious and autumnal fevers of an intermittent type are often cured by cinchona with lemon-juice, which cinchona could not affect alone, or in other combinations. The most efficacious of antidotes to sea-sickness is lemon-juice alone, or with common table-salt dissolved in it. The health of many persons on land is very greatly improved by the habitual employment of lemon-juice at meals, in preference to malt liquors; but it must be taken without sugar. Of late lemon-juice has been recommended as a cure for rheumatism, in some cases with unquestionable benefit; but it requires to be taken in large quantity, and fresh, not old imported juice, or the imitation of genuine juice made by dissolving citric acid and adding tincture of lemon-peel. Headaches of a neuralgic kind and malarious origin are often speedily relieved by pure lemon-juice. Heartburn is often relieved by the same means. Slices of lemon applied to the skin by a bandage often cure cutaneous disorders. Lime-juice is used in the West Indies in the same way as lemon-juice. Both are much employed as ingredients in punch; but sugar is an objectionable accompaniment.

ORATO'RIO (Ital.), a sacred musical composition, consisting of airs, duets, &c., and choruses. The text is generally a dramatic poem, as Handel's 'Samson,' and Cimarosa's 'Sacrifizio d'Abramo.' Sometimes it takes the form of a narrative, as 'Israel in Egypt;' and occasionally it is of a mixed kind, as Haydn's 'Creation.' The 'Messiah' is a collection of passages from our received translation of the Scriptures.

Concerning the origin of the Oratorio, Dr. Brown, Sir John Hawkins, and others seem to have misunderstood the Père Menestrier, who, in his work 'Des Représentations en Musique,' attributes to the pilgrims, on their return from the Holy Land, not the introduction of what we term oratorios, as those writers suppose, but of the sacred dramas called 'Mysteries.' And the learned Jesuit is perhaps himself in error on this subject. It is Warton's opinion that about the 8th century the merchants who frequented the fairs, employing every art to draw numbers together, were accompanied by jugglers, minstrels, and buffoons, who were the source of great amusement to the people. The clergy, thinking that such entertainments tended to irreligion, proscribed them; but their censures and fulminations being disregarded, they took into their own hands the management of popular recreations —they turned actors—and, instead of profane mummeries, presented stories taken from legends or from the Bible. ('History of Poetry.') Voltaire conjectures that religious dramas came from Constantinople, where, about the 4th century, Gregory of Nazianzus, an archbishop, and one of the fathers of the church, banished plays from the stage of that city, and introduced stories from the Old and New Testament. As the ancient Greek Tragedy was originally a religious representation, a transition was made on the same plan, and the choruses turned into Christian hymns. "This opinion," says Warton, "will acquire probability, if we consider the early commercial intercourse between Italy and Constantinople." Admitting this, we need perhaps seek no further for the original source of the sacred musical drama.

As regards the more recent introduction of the oratorio, Crescimbeni, in his 'Comentarj,' tells us that it is attributable to San Filippo Neri, born in 1515, who, in his chapel,—('*nel suo oratorio*')—after sermons and other devotions, in order to allure young people to pious offices, and to detain them from earthly pleasure, had hymns and psalms sung by one or more voices. [Neri, in Biog. Div.] Bourdelot is rather more circumstantial on this subject. He says, S. Philippe de Nery, a native of Florence, founder, in 1540, of the congregation of the Priests of the Oratory in Italy, observing the taste and passion of the Romans for musical entertainments, determined to afford the nobles and people the means of enjoying them on Sundays and festivals in his church, and engaged for this purpose the ablest poets and composers, who produced dialogues in verse on the principal subjects of Scripture, which he caused to be performed by the most beautiful voices in Rome, accompanied by all sorts of instruments. These performances consisted of airs, duets, trios, and recitatives for four voices: the subjects were, Job and his Friends; the Prodigal Son received by his father; the Angel Gabriel with the Virgin; and the Mystery of the Incarnation. Nothing was spared to render these attractive, the novelty and perfection whereof drew a crowd of auditors, who were delighted with the performances, and contributed largely, by admission money, to the expenses incurred. Hence are derived what we now call oratorios, or sacred representations. ('Histoire de la Musique,' 1743, i. 256.) Some of these poems were printed, under the title of 'Laudi Spirituali,' and among the first authors of them was P. Agostino Manni. One of the most remarkable was entitled 'Rappresentatione di Anima e di Corpo, del Signor Emilio del Cavalieri, per recitar cantando.' It was the first attempt in the recitative style, and performed in action, on a stage erected in the church of Santa Maria della Vallicella at Rome, with scenes, dances, &c., as appears from the editor's dedication to Cardinal Aldobrandini, and the composer's instructions for the performance. From the latter Dr. Burney ('Hist.,' iv. 88) gives some curious extracts, among which are the following:—

The accompanying instruments—namely, a double lyre, a harpsichord, a large guitar, and two flutes—to be behind the scenes; but the performers are desired to have instruments in their hands, as the appearing to play would help the illusion.

The books of the words were printed. Instead of the modern overture, a madrigal, with all the parts doubled, and fully accompanied, is recommended.

When the curtain rises, two youths, who recite the prologue, appear. Then *Time*, one of the characters, comes on, and has the note with which he is to begin given him by the instruments behind the scenes. The *chorus* is to be placed on the stage, part sitting and part standing; and when they sing they are to be in motion with gestures.

Il corpo (the body), at the words *Si che hormai alma via*, throws away his ornaments. The *World* and *Human Life* are to be gaily dressed, and when divested of their trappings are to appear poor and wretched, and finally dead carcasses.

The performance may conclude with or without a dance. If without, the last chorus is to be doubled in all its parts; but if a dance is preferred, a verse beginning "Chiostri altissimi" is to be sung, accompanied reverentially by the dance. During the ritornels the four principal dancers are to perform a ballet, *saltato con capriole* (danced with *capers*), without singing. They may sometimes use the *galliard* step, sometimes the *canary*, and sometimes the *courant*.

The name of *oratorios* was given, some think, to these performances, because they owed their birth to the *priests of the Oratory*. We are, however, more inclined to derive the term from the place, the *oratorio* (*oratorium*, oratory, or small chapel), in which they were first heard. But the word does not appear to have been in use till about the year 1630, when Balducci applied it to two of his sacred poems.

The unfortunate Stradella was one of the first of those who distinguished themselves in this exalted kind of composition [Stradella, in Biog. Div.]: his 'Oratorio di S. Gio. Battista,' produced about the year 1670, is analysed and much praised by Burney (iv. 105). A fine chorus from this, in five parts, is printed in the fourth vol. of 'The Fitzwilliam Music.' The increasing popularity of the sacred drama at length induced poets of eminence to employ their pens in its service. Apostolo Zeno, the imperial poet-laureate, produced seventeen works of this kind, under the title of 'Azioni Sacre,' most of which were set by Caldara, imperial vice-chapel-master to Leopold I., whose reputation as a composer of sacred music deservedly stands high. The first of them, 'Sisara,' was performed in 1717. Metastasio wrote seven 'Azioni,' of which Caldara set two; the first, 'La Passione,' in 1730. This was re-set by Jomelli, and is justly reckoned among the best of his works.

The oratorio was introduced into England in 1720, when Handel set 'Esther' (Racine's tragedy abridged and altered by Mr. Humphreys) for the chapel of the Duke of Chandos (Pope's 'Timon') at Cannons. This, in 1731, was performed by the children of the Chapel Royal, at the house of their master, Bernard Gates. The next year it was publicly produced, as appears from the following advertisement in the 'Daily Journal:'—"By his Majesty's command, at the King's Theatre in the Haymarket, on Tuesday, the 2nd of May, will be performed the sacred story of 'Esther,' an oratorio in English, formerly composed by Mr. Handel, and now revived by him, with several additions, and to be performed by a great number of voices and instruments. N.B. There will be no acting on the stage, but the house will be fitted up in a decent manner for the audience." The success of this was of the most decided and encouraging kind; but for an account of the great master's other oratorios, and of his inducement for first producing them, we refer to the life of Handel, in the Biog. Div. of this work.

The custom of performing oratorios on the Wednesdays and Fridays in Lent is to be dated from 1737, from which time they were, with few intermissions, continued till a very recent period. Handel was succeeded in this musical speculation by his friend J. C. Smith, who was followed by Stanley and the elder Linley. [Stanley, and Linley, in Biog. Div.] Linley and Dr. Arnold then in conjunction most successfully carried on the oratorios, which were continued by the latter on the retirement of his colleague. [Arnold, in Biog. Div.] An opposition was now started by Ashley, who had been active as a subordinate agent at the Commemoration of Handel in 1784. This person soon transformed the performances into secular and often vulgar concerts, though retaining the original name; and from that time the oratorios began to degenerate, till at length, having been for some years carried on by different persons, and generally at a loss, they ceased altogether. Though it would be unjust not to admit that, even during this unfavourable interval, there were two or three seasons that reflected some credit on the managers, in which 'The Messiah,' with Mozart's added accompaniments, was first publicly produced in London, and also Beethoven's 'Mount of Olives.' Of late years, chiefly through the exertions of the Sacred Harmonic Society, oratorios have been restored to more than their early popularity in this country, and are probably performed with more power, feeling, and precision than at any previous period. The oratorios of Mendelssohn have contributed not a little to this work. [MENDELSSOHN, in BIOG. DIV.]

ORATORY. The principal design of oratory is to convince or persuade. It contemplates the investigation of truth only as a secondary object. Assuming as its basis certain supposed or admitted principles or facts, its aim is, by presenting these in the form best adapted to win the assent of the understanding and impress the heart, to deter from or incline to a particular mode of resolution and action. This, the chief end of oratory, ought never to be left out of sight in any disquisition on that subject, inasmuch as upon it the general theory of the art is founded.

The oratorical art has been always held in high estimation; among the ancient Greeks, as among the rudest savages, the possession of eloquence has ever conferred a high degree of power on its possessor. Eloquence, however, does not consist in the observance of artificial rules; such rules are rather deduced from an examination of the qualities of eloquence, which depends upon peculiar mental powers, and is included in what is often termed genius, such as has distinguished many of the orators of antiquity, and some of modern times. The practice of reading, of delivery, and the improvement of the memory, should be diligently attended to by the orator. This constitutes the art of elocution, of which we now propose to treat.

Elocution is that pronunciation which is given to words when they are arranged into sentences and form discourse. It includes the tones of voice, the utterance, and enunciation of the speaker, with the proper accompaniments of countenance and gesture. The art of elocution therefore may be defined to be that system of rules which teaches us to pronounce written or extemporaneous composition with justness, energy, variety and ease; and agreeably to this definition, good reading or speaking may be considered as that species of delivery which not only expresses the sense of the words so as to be barely understood, but at the same time gives them all the force, beauty, and variety of which they are susceptible.

The Greeks and Romans paid great attention to the study of elocution, and there can be no doubt that their most celebrated orators attained to a high degree of excellence in this branch of their art; but they have left nothing on record which shows that they had made a minute analysis of the speaking voice. They did indeed distinguish its different qualities by such terms as hard, smooth, sharp, clear, hoarse, full, slender, flowing, flexible, shrill, and rigid. They were sensible to the alternations of heavy and light in syllabic utterance: they knew the time of the voice, and regarded its quantities in pronunciation: they gave to loud and soft appropriate places in speech: they perceived the existence of pitch, or variation of high and low; and noted further that the rise and fall in the pronunciation of individual syllables are made by a *concrete* or continuous slide of the voice as distinguished from the *discrete* notes produced on musical instruments. They designated the pitch of vocal sounds by the term *accent*, making three kinds of accents, the acute, the grave, and the circumflex, which signified severally the rise, the fall, and the turn of the voice, or union of acute and grave on the same syllable. But beyond this they did not go, and it was left to modern inquirers to give that clear and full description of the elements of speech, on which alone any definite instruction can be founded. For the advance which has been made in elocutionary science in modern times we are indebted to the useful labours of Steele, Odell, Walker, Thelwall, Chapman, Smart, and Rush, especially to the last, who has done much to perfect what was begun by others, and whose 'Philosophy of the Human Voice'* contains a more minute and satisfactory analysis of the subject than is to be found in any other work. From his book chiefly we shall borrow the substance of this article.

When the letter *a*, as heard in the word *day*, is pronounced simply as an alphabetic element, without intenseness or emotion, and as if it were a continuation and not a close of utterance, two sounds are heard continuously successive: the first has the nominal sound of this letter, and issues from the organs with a certain degree of fulness; the last is the element *e*, as heard in *eve*, which gradually diminishes until its close. During the pronunciation, the voice rises, by the concrete or continuous movement, through the interval of a tone, the beginning of the *a* and the termination of the *e* being severally the inferior and superior extremes of that tone. This sound commences full and somewhat abruptly, and gradually decreases in its upward movement, till it finally dies away in the upper extreme of the tone, having the increments of time and rise, and the decrement of fullness, equally progressive. The first portion therefore, or base of this sound, is called the *radical movement*, and the second portion the *vanishing movement*. This sound is called a concrete, or slide, to distinguish it from musical sounds, which (in their *pure* character) continue for a given space of time on a certain point of the scale, and then leap, as it were (*discretely*), to another point either higher or lower. These slides may extend through the space of a tone, or they may be carried up to any point on the scale to which the voice can attain, those intervals which are the most distinctly recognisable by the ear and the most easy of execution being the tone (or second), the third, the fifth, and the octave. The direction also which they take may be either upwards or downwards, the full opening radical however always occupying the first place, and the vanish the second. It also frequently happens that there is a union of the upward and downward, or of the downward and upward movement, on the same syllable: these are called *waves* or *circumflexes;* they may rise and fall through the extent of a tone, or of a third, or of any wider interval of the scale; they are then called *direct* waves: or they may fall and rise through the same extent of pitch, being then called *indirect* waves; they may be *equal*, having their constituent rise and fall through the same extent of pitch; or they may be *unequal*, having either the ascent or the descent longer than the other part.

The succession of the seven sounds of any one series, to which the octave is usually added, is called the Natural or Diatonic Scale. In speech, as in music, it consists of five tones and two semitones, the latter being the spaces between its third and fourth and its seventh and eighth degrees. But a progression may also be formed by semitones: these have only half the extent of pitch which the full tones have: like them, they may be carried upwards or downwards, and they often occur in the form of waves. They serve for the expression of animal distress.

But the succession of discrete sounds may be exhibited under still more minute divisions. These consist of a transition from place to place in pitch, over intervals much smaller than a semitone, each point being, as it were, rapidly touched by a short and abrupt emission of voice. This description may be illustrated by that noise in the throat which is called *gurgling*, and by the neighing of a horse. The analogy here regards principally the momentary duration, frequency, and abruptness of sound, for the gurgling is generally made by a quick iteration in one unvarying line of pitch, whereas in the scale now under consideration each successive pulse of sound is taken at a minute interval above the last, till the series reaches the octave. The precise extent of these small intervals it is very difficult to estimate. They may however be carried concretely through the wider interval of the scale, provided they do not lose their distinctive character of momentary time and abruptness of utterance. These concretes are used both in laughter and in crying. In the descending scale, the direction not only of the radicals but of the vanishes is downwards. *Intonation* is the act of performing the movements of pitch through the several scales.

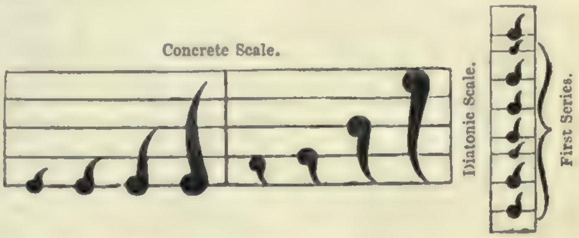
There are then *four* scales of pitch for the speaking voice:—

1. The *Concrete*, in which from the outset to the termination of the voice there is no appreciable interval, or interruption of continuity.

2. The *Diatonic*, the transitions of which are principally by whole tones.

3. The *Semitonic*, or *Chromatic*, consisting of an entire succession of semitones.

4. The *Tremulous*, consisting of minute intervals smaller than the semitone.



The *alphabet* is, in our grammars, usually divided into vowels, consonants, mutes, and semivowels; but it will be more useful to class the elements according to their use in intonation. As the number of these elementary sounds in the English language exceeds the literal signs, and some of the letters are made to represent various sounds without any rule of discrimination, it is necessary to use short words of known pronunciation, containing the elementary sounds, with the letters which represent them marked in italics. The elements of articulation are thirty-five, and they may be arranged under three general heads.

1. The first division embraces those sounds which display the properties of the radical and vanish in the most perfect manner. They are twelve in number, and are heard in the usual sound of the separated italics in the following words:—*a*-ll, *a*-rt, *a*-n, *a*-le, *o*-ur, *i*-sle, *o*-ld, *ee*-l,

---

* Second edition, 8vo, Philadelphia, 1833. See also Mr. Steele's 'Essay towards establishing the Melody and Measure of Speech, to be expressed and perpetuated by peculiar symbols,' London, 1775. The second edition was published in 1779, with the title of 'Prosodia Rationalis.' Mr. Odell's work is entitled 'An Essay on the Elements, Accents, and Prosody of the English Language,' 12mo, London, 1806.

oo-ze, *e*-rr,[*] *e*-nd, *i*-n.[†] From their forming the purest and most plastic material of intonation, these are called *Tonic* sounds. They have a more musical quality than the other elements; they are capable of indefinite prolongation; admit of the concrete and tremulous rise and fall through all the intervals of pitch, and may be uttered more forcibly than the other elementary sounds, as well as with more abruptness.

II. The next division includes a number of sounds possessing variously among themselves properties analogous to those of the tonics, but differing in degree. They amount to fourteen, and are marked by the separated italics in the following words:—*B*-ow, *d*-are, *g*-ive, *v*-ile, *z*-one, *y*-e, *w*-o, *th*-en, a-*z*-ure, si-*ng*, *l*-ove, *m*-ay, *n*-ot, *r*-oe.

From their inferiority to the tonics in all the emphatic and elegant purposes of speech, whilst they admit in some measure of being intonated, or carried concretely through the intervals of pitch, they are called *subtonic* sounds.

III. The remaining nine elements are aspirations, and have not that sort of sound which is called vocality. They are produced by a current of the whispering breath through certain positions of the enunciative organs. They are heard in the words—U-*p*, ou-*t*, ar-*k*, i-*f*, ye-*s*, *h*-e, *wh*-eat, *th*-in, pu-*sh*.

As they admit of little or no pitch, and supply no part of the concrete when breathed among the constituents of syllables, they are termed the *Atonic* sounds.

The name of *Abrupt* sounds is also given to three of the subtonics and three of the atonics, namely, *b*, *d*, *g*, *p*, *t*, *k*, since they confer an *explosive* character on the following tonic, the breath bursting out after a complete occlusion.[‡]

In conformity to the above division of the letters, and with especial reference to the time which is occupied in pronunciation, syllables are divided into three classes—1st, *Immutable*, such as *at*, *ap*, *ek*, *hap*-less, *pit*-fall, ac-*cep*-tance; 2nd, *Mutable*, as *yet*, *what*, *grat*-itude, des-*truc*-tion; 3rd, *Indefinite*, as *go*, *thee*, *for*, *day*, *man*, *till*, de-*lay*, be-*guile*, ex-*treme*, er-*ro*-neous. It is the peculiar nature of this last class of syllables, that to whatever necessary degree their quantity is prolonged, their character is still preserved, while the mutable and immutable in some cases almost lose their identity by too great an addition to their time. The use of these distinctions will appear in the sequel.

Thus much having been premised, it will be the more easy to understand the general divisions of vocal sound. All the varieties of sound in the human voice may be referred to the following general heads:—

Quality, *Force*, *Time*, and *Pitch*.[§]

I. The terms by which the *Quality* or kind of voice is distinguished are rough, smooth, harsh, full, thin, slender, soft, musical, and some others of the same metaphorical structure.

There are three different sorts of voice, the *natural*, the *falsette*, and the *orotund*, to which must be added the *whisper*, which, strictly speaking, is not *voice*. The *natural* is that which we employ in ordinary speaking. It includes a range of pitch from the lowest utterable sound up to that point at which the voice is said to break. At this point the natural voice ceases, and the higher parts of the scale are made by a shriller kind, called the *falsette*, of which the cry, the scream, the yell, and all shrillness are various modes. The name of *orotund* (from *os rotundum*) is given to that natural or improved manner of uttering the elements, which exhibits them with a fulness, clearness, strength, smoothness, and a ringing or musical quality rarely heard in ordinary speech, and which is never found in its highest excellence except as the effect of long and careful cultivation. This voice is highly agreeable to the ear; it is possessed by actors of eminence, and is peculiarly adapted to set forth the beauties of epic and tragic composition. The *whisper* is the constituent of the atonic elements; but all the tonics, and the greater part of the subtonics, may likewise be uttered in this mode of sound. The subtonics *v*, *z*, *w*, *th*-en, *zh*, when whispered, are not respectively different from the atonics *f*, *s*, *wh*, *th*-in, *sh*.

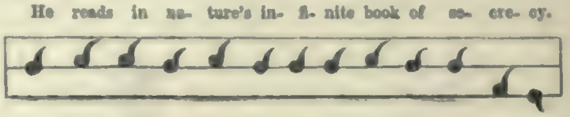
II. For the specifications of *Force* we use the words strong, weak, feeble, loud, soft, forcible, and faint. These are indefinite in their indication, and without any fixed relationship in degree.

III. *Time*, in the art of speaking, is divided into long, short, quick, slow, and rapid. These distinctious may suffice for the common purposes of discourse; if more precision is required, a notation will be found in Mr. Steele's 'Prosodia Rationalis.' The distinction of immutable, mutable, and indefinite syllables has reference to time, and has been already treated of.

IV. The meaning of the term *Pitch*, as applied to speech, has been already explained.

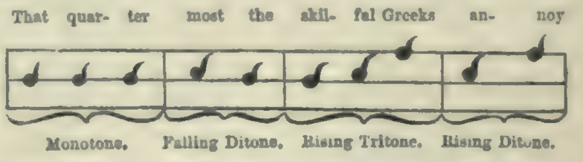
We come now to the application of these elements and distinctions to the practical purposes of reading and speech.

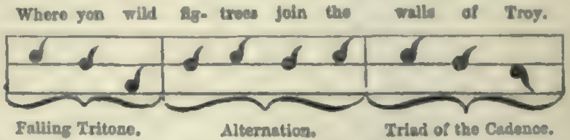
In plain narrative or description, the concrete utterance of each syllable is made through the interval of a tone, and the successive concretes have a slight difference of pitch relatively to each other. The appropriation of these concretes to syllables, and the manner in which the succession of their pitch is varied, are exemplified in the following notation:—



If these lines and the enclosed spaces be supposed, each in proximate order, to denote the difference of a tone in pitch, the successions of the radical points, with their issuing vanish, will show the places of the syllables of the superscribed sentence in easy and unimpassioned utterance, though it is not denied that a somewhat different arrangement might also be agreeable. The perception of the successions here exemplified is called (in a restricted meaning of the term) the melody of speech.

In simple phraseology, which conveys but little feeling or emphatic sentiment, most of the syllables, except one or two of the last in the sentence, consist of the upward radical and vanishing tone. The succession of these concrete tones is made with a variation of pitch, in which any two proximate concretes never differ from each other more than the interval of a tone, nor do there occur more than three successive tones in one direction either upwards or downwards. This is called the *diatonic melody*. The rise of each separate syllable is called the *concrete pitch* of melody, and the place which each syllable assumes above or below the preceding, the *radical pitch*. The *current* melody of sentences in plain discourse admits of considerable variety, but the forms of radical pitch are all reducible to a limited number of aggregates of the concrete tones, which may be called the *phrases of melody*. Their forms are pointed out in the notation of the following lines:





The *melody of the cadence*, as distinguished from the current melody, is formed on the two or three last syllables of a sentence, and is effected by a descent of radical pitch through three conjoint degrees, with a downward concrete always on the last, and frequently on the preceding. One form of the cadence has been illustrated in the sentence, the notation of which has been given above; but there are various forms according to the component parts and the sense.

Plain declarative sentences generally take one form or other of the cadence, in order to mark the satisfactory close of the period; and downward concretes are also frequently introduced into what are called loose sentences, to denote that the sense is complete, and that the succeeding clause does not modify that which precedes it. Where, on the contrary, the sense is suspended, as it most commonly is in the middle of a sentence, the concretes must have an upward direction.

For conveying the peculiarities of sentiment or feeling, or, in other words, for the *expression of speech*, a much more varied apparatus is necessary. This expression is effected by quality, time, pause, melody, pitch, the waves, the semitones, the tremor, force, and rhythm, all which are only so many forms of the four general divisions of vocal sound above specified.

I. Most of the elements which range under the general head of *Quality* have already been enumerated. It must, however, be remarked that they are susceptible of combination with the various modes and degrees of force, time, and pitch. In short, quality of voice must necessarily be united with some of the degrees of the other genera; for, whatever be the kind, it will be either strong or weak: its time must be long or short; and it must be of some definite radical or concrete pitch. Certain qualities of the voice are, however, exclusively congenial with particular conditions of these other accidents; thus smoothness will more generally affect the moderate degrees of force.

---

[*] The writer of this article has personal opportunity of knowing that by this word Dr. Rush meant to designate that sound which Mr. Cull represents by *her*.

[†] If *oi* or *oy*, as in *voice* and *boy*, be added as perhaps they ought, the number of the tonics will be thirteen.

[‡] It is difficult to decide on the analysis of the elementary sounds represented by the alphabet. That of Dr. Rush is given in the text. The following has been furnished to the writer of this article by Mr. Cull, and, although not free from objections, is more complete.

I. Vowels, as heard in the following syllables:—all, arm, an, ale, end, eel, her, isle, in, old, ooze, on, us, cube, pull, our, oil.

II. Consonants. 1. *Voice Consonants*:—be, do, go, lo, me, no, roe, vat, we, ye, zone, sing, azure, *then*, *few*.[*] 2. *Voiceless Consonants*:—up, at, ark, if, hope, quit, sin, chin, shin, *thin*, when. In all forty-three elements.

[§] To these Dr. Rush adds a fifth, namely, *Abruptness*; but this appears to be resolvable into force and time.

II. *Time.*—The degrees of duration of the voice represented by the terms long, short, and the rate by quick and slow, are among the most effective means of expression; rage, mirth, raillery, and impatience affecting a quick time; and slowness of time being the symbol of sorrow, grief, respect, veneration, dignity, apathy, contrition, and all other sentiments which embrace the idea of deliberation. A slow time of discourse, if not made by long quantities on single syllables, would be offensive from its pauses; these two forms of time therefore necessarily involve each other. Slowness of time and long quantity are generally joined with the element of the wave, since the return, or contrary flexure of intervals, is one of the means for producing an extension of time without destroying the equable concrete of speech, or, in other words, without passing into song. The wave of a tone will be perceived in the dignified and appropriate utterance of the syllables marked in italics in the following lines:—

> "*Pardon* me, thou *bleed*ing piece of earth,
> That I am meek and gentle with these butchers."
>
> "*Hail*, *ho*ly light, offspring of heaven, first-*born*,
> Or of the *eternal*, *co*-eternal beam,
> May I express thee, *unblamed!*"

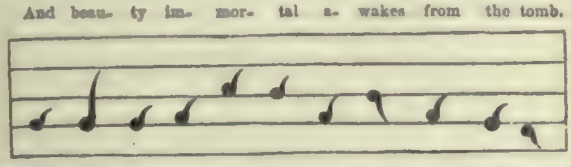
III. The use of *pause* for the more conspicuous display of sense and sentiment, by separating certain words or aggregates of words from each other, is of great consequence in elocution, but cannot be gone into at length in this article. To these pauses the grammatical points are by no means a sufficient guide. [PUNCTUATION.]

IV. A comprehensive account of *Melody* would properly represent it as produced by a variation in the time, pauses, force, and pitch of the voice, since the well-appointed uses and dispositions of these accidents make up the agreeable impression of speech; but we use it here as relating solely to the successions of radical pitch. Under this head it may be remarked that a predominance of the *monotone* is suited to feelings of dignity, grief, tenderness, solemnity, and serious admonition; that the *alternate phrase* well describes the earnest excitement necessarily produced by the rapid succession of incident; and that a *progression* gradually rising and falling through *the whole compass of the voice* corresponds with a wide variation of force in the sentiment. For illustrations of these modes see Dr. Rush's 'Philosophy of the Voice,' pp. 112, 144.

V. *Pitch.*—Discrete pitch is illustrated by the word *must* in the following passage. As it is a syllable which does not admit of prolongation, it is raised discretely a third above the preceding:—

> "If I *must* contend, said he,
> Best with the best, the sender, not the sent."

We have an example of a *concrete* rising *fifth* on *beau-*, and of a *discrete third* on *mor-*, in the following:—



If we suppose that the following words are spoken *interrogatively*, and that they express surprise, the concrete rising fifth must be given to the emphatic syllables:

> Give Brutus a statue with his ancestors?

If, on the other hand, the line be read as a *command*, the direction of the concretes will be downwards.

On the word *know*, in the following clause, not only does the voice descend concretely a third or a fifth, but the descent begins discretely a third above the preceding word:—

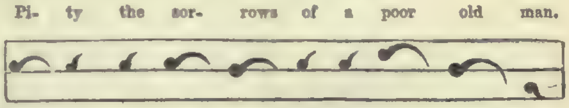
> We know what we worship, for salvation is of the Jews.

As the diatonic melody is suited to plain narration and description, so will the emphasis be the more strongly marked in proportion to the wider extent of the intervals, whether of concrete or discrete pitch, which are employed. It may also be remarked in general, that the upward concretes denote interrogation, doubt, or what is concessive, conditional, hypothetical; the downward concretes denote what is strong, certain, authoritative, as also, wonder, admiration, surprise, and exclamation, when not conjoined with an interrogative meaning.

VI. *The wave* is a very frequent element of expression, and performs high functions of speech. In its minor forms it is used to give length and emphasis to syllables and dignity to utterance: in its wider intervals it is admirably expressive of irony and derision. Thus the irony of the following passage can be brought out only by the indirect wave of a fifth in both places in which it occurs:—

> But it is foolish in us to compare Drusus Africanus and ourselves with Clodius: all our other calamities were tolerable, but no one can patiently bear the death of Clodius.

VII. *The semitones.*—These are used for the expression of complaint, pity, grief, plaintive supplication, and other sentiments congenial with these. The intonation by the concrete is universally the symbol of nature for animal distress. It affects generally a slow time and long quantity in utterance, and is therefore most commonly heard in the form of the wave. The interjective exclamations of pain, grief, love, and compassion, are prolongations of the tonic elements on this interval; but it may be executed on the short time of immutable syllables, such as *cup*. The appropriate utterance of the following line will exhibit the wave of the semitone on the most important syllables, *poor* and *old* being distinguished by direct unequal waves of the same interval. It must be taken as an isolated line, and not in conjunction with the verse of which it forms part:—



VIII. *The tremor.*—When the tremulous function is made through the second, third, fifth, or octave, or through the wave of these intervals, it joins the sentiment of derision, mirth, joy, or exultation, to that of interrogation, surprise, command, or scorn, conveyed by the smooth concrete of those intervals. In short, it is the introduction into speech of what is transferable in the function of laughter, and it adds thereto all the meaning and force of its satisfaction. Thus—

> "Thou art the ruins of the *noblest* man,
> That ever lived in the tide of times."

There is a sentiment of exultation and a superlativeness of compliment in this eulogy, which cannot be properly expressed by the smooth movement of the concrete; but if the first syllable of the emphatic word *noblest* be uttered with the tremulous intonation of the wave of the third or second, this will give the vocal consummation to the feeling which suggests the exceeding measure of the praise.

The *chuckle* is an example of a somewhat similar application.

When the tremor is formed of a single tonic, in the semitone or its waves, it constitutes the function of crying; and when employed in the syllabic intonation of the chromatic melody, it sets a more marked distinction on those emphatic words which express the sentiments of tenderness, grief, supplication, and other connatural states of feeling. This may be illustrated on the emphatic syllables of the line just quoted:—"Pity the sorrows," &c.

IX. The application of the different degrees of *Force* to the purposes of expression is almost too obvious to require illustration. Thus the *distance* of a person spoken to is pictured by loudness, and *nearness* by abatement of force; *secrecy* muffles the voice against discovery, and *doubt* adopts the subterfuge of an undertone. *Certainty* and *anger* assume force and strength. All sentiments which are *unbecoming* or *disgraceful* smother the voice into softer degrees, in the desire to conceal even the voluntary utterance of them. *Joy* is loud, and so are *bodily pain*, *fear*, and *terror*.

Such are some of the uses of force when applied to phrases, or to one or more sentences, in order to distinguish them from adjacent phrases or sentences in discourse. There are other applications of it, to single words, to syllables, and to certain parts of the concrete movement, into which, though of some consequence, it is not within the purport of this article to enter. They will be found described in Dr. Rush's 'Philosophy of the Voice.'

The common idea of *Emphasis*, it may be remarked, is that of mere force; but it is more correctly defined to be the expressive but occasional distinction of a syllable, and consequently of the whole word, by one or more of the specific modes of time, quality, force, and pitch. Most of these have been illustrated under the above heads.

X. *Rhythm* is one of the applications of force and quantity. It may be defined to be the metrical arrangement of speech. It is not mainly dependant on custom or on the genius of any language whatever, but arises from the very manner in which speech is produced, and is as involuntary as the throb or remission of the pulse, or the inhaling and respiration of the breath. In the formation of speech there is a regular action and reaction of the organs which produce it. To form a *heavy* syllable, or one which has accentual stress upon it, these organs are necessarily placed in a certain position; and from their very nature it is necessary that, before they form another heavy syllable, they should recover their first position; but the time which is occupied in this recovery of their position is not always lost to the purposes of speech, for it may be filled up with one or more syllables, which have no stress, and ,which are therefore very properly denominated *light;* if it is not filled up in this way it is a pause or rest. To illustrate this, let us take the words—

> One, two, three, four, five.

These monosyllables, if distinctly and deliberately pronounced, have two peculiarities; each has the organic stress or emphasis, and each has a pause after it. Let these pauses be filled up with the light syllable *and* ; and then the two lines, namely :—

One and two and three and four and five and

and

One, two, three, four, five,

will be of exactly the same length as to time in music, or rhythm in speech, the syllable *and* occupying no more time than what necessarily intervenes between the syllables under organic emphasis.

This alternate action and reaction of the organs of speech was called by the Greeks by the significant terms *Thesis* and *Arsis* ; the former denoting the *setting down* of a syllable, as the setting down of the foot in walking; the latter denoting the *raising of it up*, like the lifting of the foot from the ground; the former producing the heavy syllables, the latter the light ones.

The weight of syllables, or in other words, the stress with which they are enunciated, must be carefully distinguished from their quantity, since the weight or stress with which the syllable is uttered does not always correspond to the relative time which the utterance requires. Thus in the word *pensive*, the syllable *pen* is the heavier, but it is not longer than the syllable *sive*. So also in the word *inward*, there is an equality of time in the two syllables, but not of weight. In *banish, banner, banter*, the first syllable is heavy but short; in *paper, taper, vapour*, it is both heavy and long; and the same observation applies to *misery, middle, mistress*, compared with *miser, minor, mitre*.

Those emphatical divisions into which, from the very nature of the organs, all speech naturally falls, are called by writers on this subject *cadences*.* Every full *spoken* cadence consists of a heavy syllable, and of one or more light ones, but pauses may be substituted to make up the time which any of these syllables would occupy. Measure, or metre, therefore in speech naturally distributes itself into two kinds : common measure, which, according to Mr. Steele, is the allotment of two crotchets or their equivalents to each cadence ; and triple measure, which is the allotment of three crotchets or their equivalents to each cadence ; emphasis however will sometimes prolong the duration of a cadence beyond the allotted time, just as an *ad libitum* is allowed in solos in music. Without entering further into minute distinctions or exceptions, the following may serve as specimens of each kind. This mark § indicates a short pause, this ‖ a longer, and this ¶ a still longer one :—

COMMON MEASURE.

"So § | spoke the | guardian | § of the | Trojan state, |
‖Then | rush'd im- | petuous § | through the | Scæan | gate ; |
‖Him | Paris | followed | § to the | dire a- | larms : |
Both § | breathing | slaughter, § | both re- | solv'd in | arms." |
Pope's *Iliad*, b. vii.

"Straight mine | eye § hath | caught new | pleasures, |
Whilst the | landscape | round § it | measures, |
Russet | lawns § and | fallows | grey, |
Where the | nibbling | flocks § do | stray ; |
Mountains § | on whose | barren | breast
The | labouring | clouds § do | often | rest." |

TRIPLE MEASURE.

"‖§At the | close of the | day § when the | hamlet is | still,§
And | mortals § the | sweets of for- | getfulness | prove ; ‖ |
¶When | nought but the | torrent § is | heard on the | hill, §
And | nought but the | nightingale's | song § in the | grove." ‖ |

If this system of measuring verse were adopted, the prosody not only of our own but of the learned languages would be greatly simplified. The list of feet which is usually given at the beginning of the 'Gradus ad Parnassum,' would be reduced to four or five ; we should hear of no such unnatural foot as an iamb or an anapæst, and the syllable at the beginning of an iambic line would either of itself form a cadence, or would be the close of a cadence, of which a pause or the last syllable of the preceding line would form the commencement. Those lines of Anacreon would then be reduced to the trochaic measure, thus :—

‖θελ- | ω λε- | γειν'Α- | τρειδας, |
‖θελ- | ω δε | Καδμον | ᾳδειν, |
§ά | βαρβι- | τος δε | χορδαις |
‖ε- | ρωτα | μουνον | ηχει. |

From the above examples it is clear that there is a regular rhythmus in poetry ; and it cannot be necessary to insist on this being strictly attended to, if we would read verse in an agreeable and expressive manner. Prose also has its rhythmus, for the alternate action and reaction of the organs of speech necessarily proceeds, whether what is spoken be prose or verse ; and the only difference (so far as sound is concerned) between these two species of composition is, that verse consists of a regular succession of similar cadences, or of a limited variety of cadences, divided by grammatical pauses and emphasis into proportional clauses, so as to present sensible responses to the ear at regular proportioned distances ; prose, on the other hand, is composed of all sorts of cadences, arranged without attention to obvious rule, and divided into clauses which have no obviously ascertained proportion, and present no responses to the ear at any legitimate or determined intervals.

There is nothing which contributes more to the rhythmical flow of prose than giving a light sound to monosyllables. If this be done, they then form the latter part of cadences, of which either pauses, or emphatical monosyllables, or the emphasised syllables of longer words form the beginning ; but if they be pronounced heavy it is then necessary that they should themselves form the beginning of new cadences, which is the occasion of many pauses being introduced, and of a heavy and halting character being communicated to the piece. Thus the clause "Let not your | heart be | troubled," | will be rhythmical if *your* be thus made a light syllable ; but the effect will be very different if it be read thus : – "Let not | your § | heart be | troubled." |

Of the advantage of cadences in triple measure we have a beautiful illustration in the first verse of the 136th Psalm :—

‖ "O | give ‖ | thanks unto the | Lord ; ‖ | § for he is good, ‖ | ‖ for his | mercy en- | dureth for | ever." ‖ |

On the other hand, a succession of heavy syllables, with a pause intervening, is one of the most expressive forms of emphasis both in prose and verse. Thus the following line from Milton would lose all its force, if read so as to form only the usual number of six cadences emphasis prolongs it to eight, thus :—

"Rocks,‖ | caves, § | lakes, § | fens,‖ | bogs, ‖ | dens and | shades of | death."‖ |

Independently of its agreeable effect upon the ear, and its power as an element of expression, there can be no doubt that, as rhythm arises from the very manner in which speech is produced by the organs, he who speaks agreeably to its laws will speak easily to himself. The practice of reading or speaking aloud, with a due attention to the rhythmus, may even be recommended as a means of improving the health, since it brings into regular and natural action the muscles of the face, the throat, and the chest ; and no attempt completely and permanently to remove impediments of speech can be successful which is not based on the principle here developed.

(A succinct account of rhythm will be found in Wood's *Grammar of Elocution*, ch. iv. and v. ; and the subject is treated much more at length in Steele's *Prosodia Rationalis ;* in Thelwall's *Illustrations of English Rhythmus ;* in Roe's *Principles of Rhythm ;* and in Chapman's *Music, Melody, and Rhythmus of the English Language*, 8vo, Edinburgh, 1819 ; as well as in his *Rhythmical Grammar*, 12mo, 1821.)

In order to read and speak well, it is necessary to have all the vocal elements under complete command, so that they may be duly applied whenever they are required for the vivid and elegant delineation of the sense and sentiment of discourse. The student therefore should first practise on the thirty-five alphabetic elements, in order to ensure a true and easy execution of their unmixed sounds. This will be of more use than pronouncing words in which they occur ; for when pronounced singly, the elements will receive a concentration of the organic effort, which will give them a clearness of sound and a definite outline, if we may so speak, at their extremes, making a fine preparation for their distinct and forcible pronunciation in the compounds of speech. He should then take one or more of the tonic elements, and carry it through all the degrees of the diatonic and concrete scales, both in an upward and a downward direction, and through the principal forms of the wave. He should next take some one familiar sentence, and practise upon it with every variety of intonation of which it will admit. He should afterwards run through the phrases of melody, and the forms of the cadence ; and lastly he should recite, with all the force that he can command, some passage which requires great exertion of the voice. If he would acquire power and volume of utterance, he must practise in the open air, with his face to the wind, his body perfectly erect, his chest expanded, his tongue retracted and depressed, and the cavity of his mouth as much as possible enlarged ; and it is almost unnecessary to add that anything which improves the general tone of the health will proportionably affect the voice. If to this elementary practice the student add a careful and discriminating analysis of some of the best pieces which our language contains, both in prose and verse, and if he strenuously endeavour to apply to them all the scientific principles which he has learned, there can be no doubt that he will acquire a manner of delivery, which will do ample justice to any subject on which he may be called to exercise his vocal powers.

Intimately connected with the subject of delivery is that of *Action*. Oratorical action has been defined to be the just and elegant adaptation of every part of the body to the nature and import of the subject on which we are speaking. As every man who feels his subject will necessarily have some action, it is of consequence that it should be graceful and significant. The first point to be attained is to avoid awkward habits, such as resting the chief weight of the body first on one foot and then on the other, swinging to and fro, jerking forward the upper part of the body on every emphatic word, keeping the elbows pinioned to the sides, and sawing the air with one hand with one unvaried and ungraceful motion. As for the attainment of excellences, more specific rules must be sought for in professed treatises on the subject, but the following general directions will be found to embrace much that is useful: "Keep the trunk of the body erect; let your hands be at liberty; feel your subject, and the action will come; recollecting at the same time that the right hand is essentially the instrument of action, and that the left should be used only as subordinate to it."

---

* More properly *rhythmical cadences*, to distinguish them from the cadences of *melody*. Mr. Cull would prefer the term *measures*.

As gesture is used for the illustration and enforcement of language, so it should be limited in its application to such words and passages as admit of or require it. A judicious speaker will not only adapt the general style and manner of his action to the subject, the place, and the occasion, but even when he allows himself the greatest latitude, he will reserve his gesture, or at least the force and ornament of it, for those parts of his discourse for which he also reserves his boldest thoughts and his most brilliant expressions.

(On the subject of *action* very minute directions will be found in Austin's *Chironomia*; Chapman's *Music of the English Language*, Walker's *Elements of Elocution*; Richard Cull's *Acoustics and Logic in their Application to Reading aloud*, 1855; and James Hunt's *Manual of the Philosophy of Voice and Speech, especially in Relation to the English Language and the Art of Public Speaking*, 1859.)

ORB, ORBIT. The word *orbis* signifies the circumference of a circle or of any round body; *orbs* among the ancient astronomers meant the vast crystal spheres in which the heavenly bodies were supposed to be placed, and with which they revolved; hence orb came to be used for a sphere, as when the sun is called the *orb of day*. The word orbit now means the relative path [Motion] in which a planet travels round the sun, or a satellite round its primary.

We should perhaps rather say that by the orbit of a planet, technically speaking, is meant the approximate path, circular or elliptic, in which the planet may for a time be supposed to move without sensible error. Thus, when for some particular purpose, as the explanation of the seasons, we say the earth moves round the sun in a circle, we make an orbit which is exact enough for that purpose; and when, to explain the equation of time, we are obliged to have recourse to a more exact supposition, that of an elliptic motion, we are still said to speak of an orbit of the earth. But if we were to speak of the closely-folded interlacing spiral in which the centre of the earth actually moves round the sun, usage (and nothing else) would require us, if we would be understood, not to call this the orbit of the earth, but its real path, or real orbit, or some such distinctive term; for it is generally understood that the word orbit applies at most to the ellipse, which for a time does not differ sensibly from the real path. Theoretically speaking, this ellipse only touches the real path in one point; and the ellipse which most exactly tends to coincidence with the real path, consistently with satisfying other desirable conditions, is called the instantaneous ellipse. [Gravitation.]

The *elements* of the orbit are those quantities by which the position and magnitude of the (*pro tempore*) orbit are fixed, such as the major axis and eccentricity, which determine its magnitude; the longitude of the node and inclination of its plane to the ecliptic, which determine the position of that plane in space; and the longitude of the perihelion, which determines the direction of the major axis. One more determining quantity is tacitly supplied in the condition that one focus of the ellipse is always to be in the centre of the sun. The only remaining element is the periodic time of the planet, or its time of revolution round the sun; this however is not a separate element for each planet, but, all the other elements being given, is known for every planet when it is known for any one.

ORCEIN. [Lichens, *Colouring matters of*; Orcin.]

ORCHARD. Apples, pears, plums, and cherries are the fruits principally cultivated in orchards. The term orchard is likewise used to signify enclosures in which filberts or walnuts are grown: the word yard is commonly used for similar spaces appropriated to the production of figs and grapes.

Orchards of apples and pears are more numerous, because more productive, on the old and new red-sandstone formations than on any other strata; a very large proportion of all the cider and perry that is manufactured is grown upon these soils. The principal orchards of England are in Devonshire, Somersetshire, Gloucestershire, Herefordshire, and Worcestershire; on the continent, in Normandy and in the vale of Stuttgard; and in America, in the New England states.

For an orchard of apple-trees, a deep unctuous soil should be selected, in a situation sheltered from the north and north-west winds, and open to the south and south-east; and a bank is preferable to a low spot, for not only is the blossom more liable to be injured by spring frosts where fogs and damp prevail, but the trees themselves become mossy, and perish from excess of moisture. Dr. Lindley ('Guide to Orchard and Kitchen Garden,') recommends an early and effectual preparation of the soil, and the early transplanting of the trees. Young trees will require to be watered if a dry spring should succeed the autumn of their planting, and their roots should be occasionally dug round and manured. Pruning is advantageous to young trees when skilfully performed, for it is desirable that branches should not be crowded together, especially in the centre of the tree: we are of opinion that it is seldom beneficial to old trees, excepting for the removal of misletoe; and recommend that under no circumstances should a pruner be employed who amputates large limbs and leaves wounds which injure the alburnum or sap-wood by exposing it to the atmosphere, and produce canker in the stem or principal branches. It may frequently be useful in an exposed situation to plant two or three rows of pear-trees to shelter the apple-trees from the prevailing storms, as pear trees are on the whole less liable to suffer from wind than their more brittle kindred. The trampling of heavy cattle is at all times injurious to orchards.

For pear-orchards a lighter soil is desirable than for apples; the same rules may be observed for their planting and preservation. Washes for the destruction of the eggs of insects, and directions for the preservation of orchard-trees from barking by hares, rabbits, and sheep, are given in Lindley; Forsyth 'On Fruit Trees;' and Loudon's 'Arboretum.' For further information see articles Apple, Cider, and Pear.

The principal cherry-orchards in England are in Buckinghamshire and Kent; from the latter county a large supply is sent to the London markets. In Alsace, Würtemberg, Berne, and Basle, "kirschwasser," an ordinary spirit, is distilled from cherries. There are likewise orchards of a small acid cherry called "marasca" in the neighbourhood of Trieste, and also near Zara in Dalmatia, from which Maraschino is derived: in the Bergstrasse, near Heidelberg, there are cherry-orchards which furnish an early supply to the London market. The cherry and plum require but little pruning.

In all cases, as is judiciously pointed out by Mr. MacIntosh ('Book of the Garden,' vol. ii.) it is of great importance that good sorts should be introduced into, and the worthless extirpated from, our orchards as soon as possible. The importation of good foreign fruit has rendered the continued growth of inferior sorts a practice that must certainly result in loss. Much has been done in this direction by market gardeners.

For filbert and walnut orchards see Filbert and Walnut.

ORCHESTRA (Gr. ὀρχήστρα, which contains the same element as the verb ὀρχεῖσθαι, "to dance"), that part of the Greek theatre in which the chorus was situated—where the dances were performed. [Theatre.] With the moderns, the orchestra is the place in the theatre allotted to the instrumental band, and that portion of a concert-room which is assigned to the musical performers, both instrumental and vocal. We not only apply the word to the place set apart for the musicians, but often use it to designate the whole of them collectively; in which case, *orchestra* and *band* are treated as synonymous terms.

Till the end of the 17th century or the beginning of the 18th, the instrumental performers of our theatres were stationed in a box on the side of the stage, and out of view of the greater portion of the spectators. They were then few in number. But, however desirable in some respects, it would be impossible so to dispose of the large bands of the present day; and all things considered, they could not be better placed than where they now are—just below the stage, so as not to interrupt the sight, and between the singer and the audience, thus enabling the former to have in view the conductor and leader—a matter of great importance in the musical drama, where all is sung by memory.

The orchestra of a concert-room should be so contrived that the front, when no passage beneath it is required, is about five feet higher than the level of the room, and it should rise rather steeply to the back, the corners of which ought to be rounded off, in order that the whole body of sound may be directly reflected. But the due apportionment of the orchestra to the size and character of the room, and the requirements of the immense masses of vocal and instrumental performers now employed in the execution of oratorios, &c., is a matter that demands great knowledge of the laws of sound and considerable adaptive skill on the part of the architect. None of the great music halls yet constructed in this country can be considered as perfectly successful in this respect.

ORCHIL. [Lichens, *Colouring matters of.*]

ORCIN ($C_{14}H_8O_4+2Aq.$) *Alphaorcin.* It has already been stated [Lichens, *colouring matters of*] that this peculiar crystalline principle exists to a small extent in the free state in many of the lichens. It is largely produced, however, when lichens are exposed to the joint influence of heat and alkalies, conditions that always exist in the manufacture of *archil, litmus, cudbear* and other colour derivatives of the lichens. Under these circumstances, some acid substances that occur naturally in the lichens are split up into secondary acids and *orcin*, the latter immediately undergoing further alteration by absorbing oxygen and nitrogen, and becoming converted into a deep purple or red-coloured body termed *orcein*. By skilful management the operation may be arrested at any stage, various tints being thus obtained, or orcin itself may be extracted.

Stenhouse gives the following directions for isolating orcin: exhaust the lichens with water containing lime, boil the strained liquor till it is concentrated to about one-fourth its original bulk, separate lime by a current of carbonic acid, filter, evaporate to a syrupy consistence, treat with boiling absolute alcohol, and set aside to crystallise. The orcin thus obtained is usually of a red colour, but may be perfectly decolorised by two or three recrystallisations from ether.

Pure orcin crystallises in colourless quadrangular prisms, and is very soluble in water, alcohol, or ether. It is neutral to test paper, has a mawkish sweet taste, loses its two equivalents of water when moderately heated, or when exposed in vacuo, or even when crystallised from anhydrous ether. It sublimes in needles on being slowly heated in flat vessels; is precipitated white by acetate of lead, and red by perchloride of iron; is converted first into a resin, and finally into oxalic acid by nitric acid; and gives an intense purple-red colour, quickly changing to yellow, with chloride of lime.

Brom-orcin ($C_{14}H_5Br_3O_4$) was discovered by Stenhouse. It is formed on adding bromine to a concentrated aqueous solution of orcin, and may be obtained in silky needles by crystallisation from dilute alcohol. It is very fusible, insoluble in water, but soluble in alcohol or ether.

Chlor-orcin is produced in the same way, and much resembles brom-orcin. Its exact composition has not yet been ascertained.

In the presence of ammonia orcin rapidly absorbs oxygen, and is converted into *orcein* :—

$$\underbrace{C_{14}H_8O_4}_{\text{Orcin.}} + \underbrace{NH_3}_{\text{Ammonia.}} + \underbrace{O_6}_{\text{Oxygen.}} = \underbrace{C_{14}H_7NO_6}_{\text{Orcein.}} + \underbrace{4HO}_{\text{Water.}}$$

Orcin may be precipitated from its dilute ammoniacal solution by the addition of acetic acid; it then falls in red flocks, almost insoluble in water, readily so in alcohol and sparingly so in ether. It is very soluble in alkalies, forming rich purple solutions. Its solutions are decolorised by nascent hydrogen and again become coloured by exposure to air, but if ammonia is added before exposure, an abundant white precipitate of *leucorcein* is thrown down. Leucorcein becomes purple in contact with air.

Chlor-orcein is a yellowish-brown substance, formed on passing chlorine through water containing orcein. It is insoluble in water, but soluble in alcohol or ether.

ORDEAL, from the Anglo-Saxon *ordæl*. Spelman derives this word from *or*, "magnum," and *dæl*, "judicium," which is also the derivation given by Ducange. Lye and Bosworth derive it from *or*, privative, "without," and *dæl*, "difference," an indifferent or impartial judgment, a judgment without distinction of persons. The German word *urtheil*, a judgment, is apparently the same word, and is also a compound.

The earliest traces of any custom resembling the ordeal is found in the book of Numbers (ch. v.), in the waters of jealousy, which the Hebrew women suspected of adultery were compelled to drink as a test of their innocence.

Blackstone, speaking of the several methods of trial and conviction of offenders, says, "The most ancient species of trial was that by *ordeal*, which was peculiarly distinguished by the appellation of *judicium dei*, and sometimes *vulgaris purgatio*, to distinguish it from the canonical purgation, which was by the oath of the party. This was of two sorts, either fire-ordeal or water-ordeal; the former being confined to persons of higher rank, the latter to the common people. Both these might be performed by deputy; but the principal was to answer for the success of the trial, the deputy only venturing some corporal pain for hire, or perhaps for friendship. Fire-ordeal was performed either by taking up in the hands unhurt a piece of red-hot iron of one, two, or three pounds weight or else by walking barefoot and blindfold over nine red-hot ploughshares, laid lengthwise at unequal distances; and if the party escaped being hurt, he was adjudged innocent; but if it happened otherwise, as without collusion it usually did, he was then condemned as guilty. However, by this latter method Queen Emma, the mother of Edward the Confessor, is mentioned to have cleared her character when suspected of familiarity with Alwyn, bishop of Winchester. Water-ordeal was performed either by plunging the bare arm up to the elbow in boiling water, and escaping unhurt thereby, or by casting the person suspected into a river or pond of cold water, and if he floated therein without any action of swimming it was deemed an evidence of his guilt, but if he sunk he was acquitted." Another species of ordeal was the corsned, or morsel of execration: this was a piece of cheese or bread, about an ounce in weight, which was consecrated with a peculiar form, and it was prayed that the bread might cause convulsions and paleness, and find no passage, if the man was really guilty, but might turn to health and nourishment if he was innocent. The corsned was then given to the suspected person, who received the holy sacrament at the same time,—if, indeed, as some have suspected, the corsned was not the sacramental bread itself.

The Ordeals of water and iron are first mentioned in the 77th law of Ina; and afterwards in those of Athelstan, Edward the Confessor, and the Conqueror.

In 'Domesday' the readiness of claimants to prove their title to land, by ordeal or by battle, occurs in a great variety of instances: as among the lands belonging to the monastery of Ely, at a place then called Photesturp, in Norfolk: "Hanc terram calumpniatur esse liberam Vlchetel homo Hermeri quocunque modo judicetur, vel bello vel *Juditio*." (See tom. ii., fol. 213, and other instances, fol. 110 b, 137, 162, 166, 172 b, 193, 208, 277 b, 332.) 'Ferri candentis Judicium (the ordeal of hot iron) is the only ordeal of the Domesday Survey.' The reason for this is given by Glanville (l. xiv., ch. 1): "in such a case the accused is bound to clear himself by the judgment of God, namely, by hot iron, or by water, according to the difference of rank, that is, by hot iron if he should be a free man, and by water if he should be a villein (si fuerit rusticus)."

Eadmer ('Hist. Novor.,' p. 48) speaks of no fewer than fifty persons of Saxon origin who, in the reign of William Rufus, being accused of killing the king's stags, were at one time sentenced to the fire-ordeal.

It is probable that the Trial by Ordeal was not discontinued in England by any positive law or ordinance, although Sir E. Coke (9 *Rep.*, 32), and after him Blackstone (4 *Comm.*, 315), have expressed an opinion that it was finally abolished by an act of parliament, or rather an order of the king in council, in the 3 Henry III. (1219). This order is to be found in Rymer's 'Fœdera,' vol. i., p. 228; Spelman's 'Glossary,' sub voce *Judicium Dei*; and in Selden's 'Notes to Eadmer.' Spelman, however, thinks that this was merely a temporary law, without any general or permanent operation, and that the Trial by Ordeal continued to a later period. This opinion seems confirmed by a reference in the 'Cal. Rot. Pat.,' p. 15, to another order in council in the 14 Henry III., 'De justitiâ faciendâ loco ignis et aquæ.' As, however, it is only mentioned as a former custom, and not as an existing institution, by Bracton (lib. iii., cap. 16), who wrote at the end of the reign of Henry III. or the commencement of that of Edward I., it is probable that, in consequence of the judgments of councils and the interference of the clergy, the Trial by Ordeal fell into disuse about the middle of the 13th century (Selden's 'Notes to Eadmer'), but this was long after it had disappeared from the judicial systems of most other European nations.

Blackstone, in the part of his 'Commentaries' already quoted, says, "Purgation by ordeal seems to have been very ancient, and very universal in the times of superstitious barbarity. It was known to the ancient Greeks: for in the 'Antigone' of Sophocles (v. 270) a person, suspected by Creon of a misdemeanor, declares himself ready 'to handle hot iron, and to walk over fire,' in order to manifest his innocence; which the scholiast tells us was then a very usual purgation." And Grotius (on 'Numb.' v., 17) gives us many instances of water-ordeal in Bithynia, Sardinia, and other places.

"In Siam, besides the usual methods of fire and water-ordeal, both parties are sometimes exposed to the fury of a tiger let loose for that purpose: and if the beast spares either, that person is accounted innocent; if neither, both are held to be guilty; but if he spares both, the trial is incomplete, and they proceed to a more certain criterion." ('Mod. Univ. Hist.,' vol. vii., p. 266.)

The 'Asiatic Researches' (vol. i., 4to. Calcutta, 1788, p. 389-404) contain a memoir on the trials by ordeal among the Hindus, by Ali Ibrahim Khán, chief magistrate at Benares, communicated by Warren Hastings, Esq., nine in number:—1, by the balance; 2, by fire; 3, by water; 4, by two sorts of poison; 5, by Cosha, in which the accused drinks of water in which the images of the sun and other deities have been washed; 6, by chewing rice; 7, by hot oil; 8, by hot iron; 9, by Dharmach, in which an image named Dharma, or the genius of justice, made of silver, and another of an antagonist genius Adharma, made of clay or iron, or those figures painted respectively on white and black cloth, are thrown into a large jar, from which the accused is instructed to draw at hazard.

The Latin forms of service for the different species of ordeal, as anciently used in England, are given by Spelman in his 'Glossary,' *in v.* from the Textus Roffensis.

The reader may consult for further information Grimm's 'Deutsche Rechts-Alterthümer, Gottesurtheil.'

ORDER is distinguished from *degree* in mathematical language by a purely conventional boundary. Both are terms of succession; thus an expression is of the first, second, third, &c., degree, according as its highest power is the first, second, third, &c., of the principal letter. But if another succession should occur, say one of differentiations, then the number of such successive operations is the order of the process. Thus a differential equation which contains, at the highest, the fifth power of a differential co-efficient, is said to be of the fifth degree; while if the highest differential co-efficient which occurs in it is the third, it is said to be of the third *order*.

There is a particular use of the word *order* in regard to quantities which increase or diminish without limit. If A and B both diminish without limit, but if A diminish without limit with respect to B [INFINITE], A is said to be of an inferior order to B; and generally the first powers of small quantities are said to be of the first order; products of two small quantities, and second powers, of the second order; and so on.

ORDER IN COUNCIL. [PRIVY COUNCIL.]

ORDERS, HOLY. [ORDINATION.]

ORDINARY. This term, when used in English law, commonly signifies the bishop of the diocese, who is in general, and of common right, the ordinary judge in ecclesiastical causes arising within his jurisdiction. (Lindwoode's 'Provinciale,' lib. i., tit. 3.) The term is also applied to the commissary or official of the bishop, and to other persons having, by custom or peculiar privilege, judicial power annexed to their offices or dignities. Thus an archdeacon is an ordinary. A bishop therefore is always an ordinary, but every ordinary is not a bishop.

The term is derived from the Canonists, and is in common use in several European countries. Since the Lateran council, when the apostolic see assumed the power of presenting to benefices, the pope has sometimes been called by canonical writers "ordinarius ordinariorum." The judex ordinarius of the canon and of the later Roman law is a judge who has judicial cognisance in his own proper right, as such judge, of all causes arising within the territorial limits of his jurisdiction. He is opposed to the judex delegatus, or extraordinarius, whose jurisdiction extends only to such causes as are specifically delegated to him by some superior authority. (Ayliffe's 'Parergon,' p. 309; Justin., 'Novell.,' 20, c. 3 and 112, c. 31.) With reference to this distinction, it became usual to apply the term "ordinary" to bishops, who, when acting in their judicial character in ecclesiastical causes, have strictly an ordinary jurisdiction; and we find it used in this sense by Bracton and the earliest writers upon English law.

ORDINATE is that particular rectangular Co-ordinate of a curve which is measured perpendicularly to one of the axes and not upon an axis. [CO-ORDINATE.] It is necessary to observe that though the term co-ordinate has been extended to what are called polar co-ordinates, yet the word ordinate is not separately used in the latter system. The etymology of ordinate will be found in the article cited.

ORDINATION, the ceremony by which holy orders are conferred, or by which a person is initiated into the ministry of religion, or set apart for preaching, administering the sacraments, and discharging other ecclesiastical rites and duties, public or private. In the Church of England, a candidate must be twenty-three years of age before he can be ordained deacon, and twenty-four before he can be ordained priest; must have an appointment to some cure, except he be a fellow of a college; bring letters testimonial of his life and doctrine, for three years, from three beneficed clergymen; undergo an examination in Latin, Greek, and theological learning; subscribe to the Thirty-nine Articles and the Liturgy; and, as bishops now almost invariably require, have graduated at one of the English universities, at Trinity College, Dublin, or at some other recognised school. No person can hold any vicarage, rectory, or benefice whatever, except he be in full orders.

A form of some kind has always been observed in conferring the priesthood. This was the case under the Old Testament dispensation; in which the family, age, and qualifications of the individual appointed, are particularly described. In the New Testament, our Lord called the twelve apostles, and sent them out—ordained them to perform the offices of religion. So likewise the apostles ordained others; and the form they adopted for setting them apart was *prayer* and the *imposition of hands*. In this manner bishops, priests, and deacons were appointed; and, for at least ten centuries, no other ceremony was used or added thereto. When the church became corrupt, this, like almost every other ordinance, shared the general perversion. It lost its primitive simplicity, and was elevated to the dignity of a sacrament. The plan was adopted of delivering to a person ordained priest the *sacred vessels*, that is, the plate and the cup; employing with the action certain words by which he was authorised to offer sacrifice to God, and to celebrate mass. To constitute a sacrament, three things are required, *matter*, *form*, and *institution*. Ordination was evidently instituted by Jesus Christ and his apostles; but in their institution of it, it clearly wants the main essentials of a sacrament. The church of the 11th century, in converting it into a sacrament, considered the *vessels* as the *matter*, and the *form* was the delivering them with the words:—"Take thou authority to offer up sacrifices to God, and to celebrate masses, both for the living and the dead; in the name of the Father, the Son, and the Holy Ghost." Protestant churches have returned to the original method of conferring orders, and use only prayer and the imposition of hands; some sects dispense with the latter, as the Wesleyan Methodists.

The great controversy between Episcopalians and Presbyterians is, the authority by which holy orders are conferred. The former hold that bishops alone are vested with this authority; and those especially who entertain the notion of *Apostolic succession*, that is, assert the fact of an unbroken episcopal series from the days of the Apostles to the present time, to which the power of ordaining ministers is confined and through which it descends, deny the validity of orders and even the existence of a church, where there is no bishop. The Presbyterians, on the contrary, contend that the presbytery, or a body of priests, have authority for this purpose; and that bishops and presbyters are in Scripture the same, and not distinct orders or officers. They urge that Timothy was ordained by the laying on of the hands of the presbytery; and that Paul and Barnabas were ordained by certain teachers and prophets in the church of Antioch, and not by any bishop presiding in that city. It is certain however that bishops have existed as a distinct order from the very earliest times; and though we cannot assert that they are absolutely essential, yet they evidently contribute to complete the idea of a church, and tend to its orderly and effectual operation.

Many at the Reformation held the call of the people the only thing essential to the validity of the ministry, and taught that ordination is only a ceremony which renders the call more solemn and authentic. Accordingly the Protestant churches of Scotland, France, Holland, Switzerland, &c., and the dissenting churches of England, have no episcopal ordination. For Luther, Calvin, Bucer, Melancthon, and all the first reformers and founders of these churches, who ordained ministers among them, were themselves presbyters and no other. There are some remarks on this subject, at once liberal and judicious, in Burnett's 'Exposition of the Thirty-nine Articles.'

ORDNANCE, a general term applied to the great artillery (guns, carronades, howitzers, and mortars) which is used in war, on land or at sea; the name being probably derived from the *compagnies d'ordonnance*, or France Archers, instituted in 1448 by Charles VII. of France.

The wars between the emperor Charles V. and Francis I. gave rise on the Continent to the first important improvements in the construction and use of heavy artillery. According to Templehof it was then that some efforts were made to establish a system of proportions between the length, the thickness, and the calibre of ordnance; that gunpowder was improved, and that certain relations between the charge of powder and the weight of the projectile began to be established. It was not, however, till the beginning of the 17th century that artillery, which had before been chiefly used in the attack and defence of fortresses, began to be extensively employed in engagements between hostile armies; but in 1632 the Austrians and Swedes together are said to have brought into the field 2000 pieces, among which were 24, 16, 12, and 6 pounder guns.

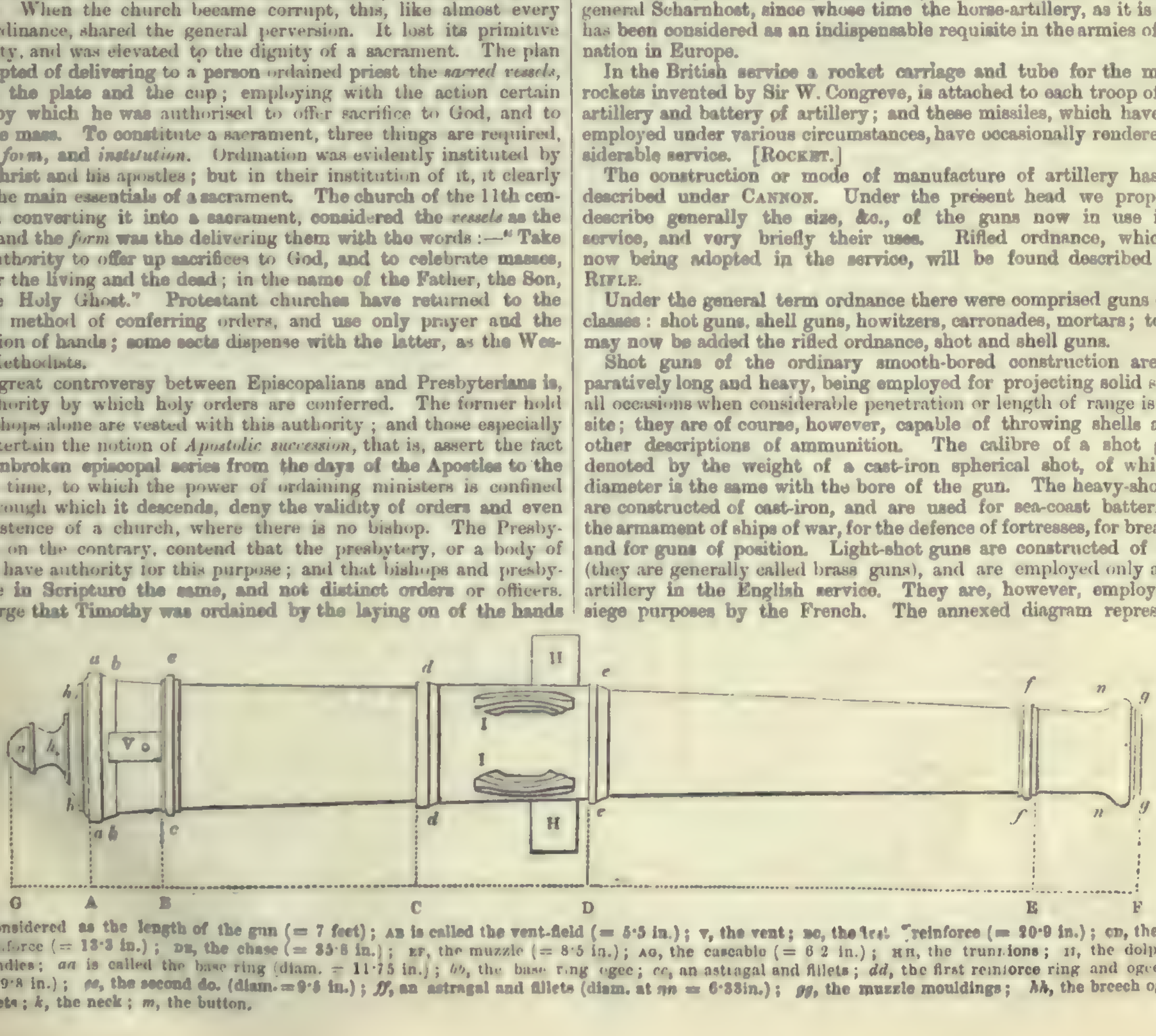
An artillery capable of accompanying the rapid movements of cavalry, was first systemically introduced into warfare by Frederic the Great [ARTILLERY]; but the full development of the important services which are capable of being rendered by this arm is due to the Prussian general Scharnhost, since whose time the horse-artillery, as it is called, has been considered as an indispensable requisite in the armies of every nation in Europe.

In the British service a rocket carriage and tube for the military rockets invented by Sir W. Congreve, is attached to each troop of horse artillery and battery of artillery; and these missiles, which have been employed under various circumstances, have occasionally rendered considerable service. [ROCKET.]

The construction or mode of manufacture of artillery has been described under CANNON. Under the present head we propose to describe generally the size, &c., of the guns now in use in the service, and very briefly their uses. Rifled ordnance, which are now being adopted in the service, will be found described under RIFLE.

Under the general term ordnance there were comprised guns of five classes: shot guns, shell guns, howitzers, carronades, mortars; to these may now be added the rifled ordnance, shot and shell guns.

Shot guns of the ordinary smooth-bored construction are comparatively long and heavy, being employed for projecting solid shot on all occasions when considerable penetration or length of range is requisite; they are of course, however, capable of throwing shells and all other descriptions of ammunition. The calibre of a shot gun is denoted by the weight of a cast-iron spherical shot, of which the diameter is the same with the bore of the gun. The heavy-shot guns are constructed of cast-iron, and are used for sea-coast batteries, for the armament of ships of war, for the defence of fortresses, for breaching, and for guns of position. Light-shot guns are constructed of bronze (they are generally called brass guns), and are employed only as field artillery in the English service. They are, however, employed for siege purposes by the French. The annexed diagram represents a



AF is considered as the length of the gun (= 7 feet); AB is called the vent-field (= 5·5 in.); V, the vent; BC, the first reinforce (= 20·9 in.); CD, the second reinforce (= 13·3 in.); DE, the chase (= 35·8 in.); EF, the muzzle (= 8·5 in.); AG, the cascable (= 6·2 in.); HH, the trunnions; II, the dolphins or handles; *aa* is called the base ring (diam. = 11·75 in.); *bb*, the base ring ogee; *cc*, an astragal and fillets; *dd*, the first reinforce ring and ogee (diam. = 9·8 in.); *ee*, the second do. (diam. = 9·5 in.); *ff*, an astragal and fillets (diam. at *nn* = 6·33in.); *gg*, the muzzle mouldings; *hh*, the breech ogee and fillets; *k*, the neck; *m*, the button.

brass gun (a heavy six-pounder). Shell guns differ from shot guns in being of greater calibre in proportion to their weight of metal. The bore of shell guns is also contracted towards the breech, thus forming a chamber. The size of shell guns is denoted by the diameter of the bore in inches. Shell guns are employed for projecting shell and hollow shot, and are principally for sea service. They are made of iron. Guns of 12-inch diameter have been made, but the sizes employed in the service now are the 10-inch and 8-inch guns only.

We have subjoined a table of the dimensions and weights of the principal natures of guns in use in the British service. The natures and uses of carronades, howitzers, and mortars have been already described under those words.

The axis of the trunnions is at right angles to that of the gun, and is usually about half their diameter below the latter axis; but Dr. Gregory, in his 'Lectures on Gunnery,' recommends that it should intersect the axis of the gun, in order that the recoil of the piece in firing may act less on the carriage. The vent is two-ninths of an inch in diameter, and it enters the bore at about eight-tenths of an inch from the bottom of the latter.

S, Sea service; L. Land service; S L, both; M, Millar; M′, Monk; O, Ordinary.

The diameter of the bore is called the calibre of the gun; this is rather greater than the diameter of the shot by which the nature of the gun is designated, and the difference between them is called the windage. [Windage.]

A scale of quarter degrees is graduated on the base ring, the zero line being in a plane passing through the axis of the gun and cutting the exterior surface immediately above the trunnions, and the intersection of such plane with the side of the muzzle is marked by a notch on the latter. These quarter-sights, as they are called, serve to give the gun an elevation not exceeding three degrees; and this is accomplished by lowering the breech till the division expressing the intended elevation and the notch on the side of the muzzle are in a line with the object. The axis of the gun will then be inclined to a plane passing through the object and the axis of the trunnions, in an angle equal to that which is indicated by the division above mentioned.

A point-blank disposition of the gun is that in which the zero notch on the base ring and that on the side of the muzzle are made to coincide in direction with the object, whether this line of direction be or be not parallel to the horizon. But when a notch on the top of the base ring and one at the top of the muzzle are made to coincide in direction with the object, the gun is said to have the *line of metal elevation*. [Gunnery.] The angle which the axis of the gun, in this case, makes with a plane passing through the trunnions, and the object, varies with the nature and construction of the gun, but is generally about one degree.

For elevations greater than three degrees a tangent scale is employed; this is a brass rod which slides up and down in a groove formed in the direction of a diameter to the base-ring of the gun, and is divided into quarter degrees. In using this scale the latter is drawn up till the graduation expressing the intended elevation is at the surface of the base-ring; then the breech of the gun is lowered till a notch at the top of the scale and that at the top of the muzzle are in a line with the object. The axis of the gun (allowance being made for the difference between the semidiameters of the base-ring and muzzle [Dispart]) is then inclined to a plane passing through the trunnions and the object in an angle indicated by the said graduation.

It was considered advisable at one time to convert a number of heavy guns into a description of shell gun by boring or *reaming up*, that is, re-boring and enlarging the bore of various guns in the service to the next higher calibre: thus, 24-pounders were bored up into 32-pounders. The practice was first recommended by Colonel Paixhans, in France.

The application of locks to naval ordnance was introduced by Sir Charles Douglas (captain of the fleet to Admiral Rodney in the action of 1782), and their efficiency was soon fully recognised. At first the locks were made with one flint only, and in the event of this becoming unserviceable the loss of time attending the fixing a fresh flint was found to be so great, that instead of renewing the flint, recourse was generally then had to the lintstock or port-fire. But this defect was removed by the construction of a lock which carried two flints, so disposed, that on the failure of one, by simply turning the nut, the other might be brought into use. This improvement was made in 1818, by Major-General Sir Howard Douglas; it was immediately introduced in the British navy, and was afterwards adopted in the land-service artillery. This was followed soon afterwards by the introduction of the percussion tube into the navy and heavy artillery, and the friction tube for field artillery, and indeed for heavy artillery also often when on shore. The percussion tube is fired by a hammer which is made to strike simply by a pull on a lanyard attached to it. It is so contrived that after striking it is withdrawn from the vent and therefore not thrown back by the explosion of the powder. The friction tube is fired by sharply pulling out a portion of the head which projects above the vent, and which is made with an eye for the insertion of the hook of the lanyard.

From experiments made in France it was ascertained that hollow shot, being with equal weight greater in diameter than such as are solid, when fired with low charges of powder against ships, produced most dangerous breaches in their sides; and, in consequence, certain heavy iron howitzer-guns for discharging such missiles were introduced in the French navy. Similar experiments, attended by like results, were in 1828 made in this country by the late General Millar, with a short and massive 12-inch gun which he invented on the occasion. The hollow shot projected from this piece of ordnance weighed 120 pounds, and being impelled by 11 pounds of powder, producing an initial velocity of 1000 feet per second, it pierced, at the distance of 400 yards, a strong frame-work of timber, making an opening which would have seriously compromised any ship so struck. A conviction of the necessity of using these powerful arms in a future war led the British government to adopt 8- and 10-inch guns in the royal navy, and now the ships of war always carry a certain number of such guns.

Various experiments were made in France, England, and America, on the effect of shells fired into and exploded in ships, the fuses being cut of such a length as to explode the shell after striking; or, still better, by means of concussion fuses. The destructive effects were so great that shells and shell guns were at once adopted in the navy, and form a large portion of the armament, though the existence of loaded shells on board of ships has been objected to on account of the danger which might ensue from the accidental ignition of their fuses. This danger, however, may be much lessened by keeping each shell in a separate box, and by covering the fuse with a metallic cap till the moment when it is required to be put in the gun.

The carriages for guns vary much according to the calibre of the gun and the objects to which they are to be applied, or the mobility required.

The field gun carriage, in which great lightness and mobility combined with strength are required, is composed of one large solid piece termed the trail, to which two small brackets are attached, one on each side. The trail rests at one end on the axletree of a pair of high wheels. The trunnion holes are cut in these brackets: as it is necessary to come into action very rapidly there is only one set of trunnion holes in a field gun carriage, and they are placed far back on the carriage over the rear of the axletree, which has been found to be the best position both on account of the reduced strain on the carriage when fired, and of the ease with which the trail can be lifted to limber up or unlimber the gun. When the gun is in action the rear extremity of the trail rests on the ground, but when it is required to be moved, the end of the trail which is fitted with an eye is raised and placed on a hook in the limber.

The limber is a bed, with shafts, mounted on two wheels, and carrying two ammunition boxes for the service of the gun; the horses are harnessed to the limber, and the gun with its carriage is drawn after the latter. An ammunition waggon also accompanies each piece of ordnance, and there are others always in reserve.

Field howitzer carriages and their limbers are similar to those just mentioned, but stronger.

Carriages of a light construction are employed for the small artillery which is used on service in mountainous countries.

The travelling carriages for siege-ordnance are made wholly of oak, and the limber carries no ammunition; the great size and weight of the gun-carriage trail not permitting, when it rests on the limber, the boxes to be placed there. The trail of siege-carriages is made of two cheeks or side pieces firmly attached together by means of transoms, and resting on the axletree of the wheels, instead of in a single piece or block trail, as with field gun-carriages.

Carriages for garrison service and for the navy consist of two short cheeks or brackets, connected by transoms, and they move on four truck-wheels. Garrison carriages are now often made of cast-iron, which is more durable than wood, particularly in tropical climates. High platforms of timber or cast-iron are also occasionally placed at the salient angles of fortresses; they are made to turn at one extremity upon a vertical pivot, the other extremity traversing through ninety or a greater number of degrees. The usual garrison carriage is mounted upon this platform, and thus the piece can be fired over the parapet in any direction at pleasure. There is also a species of mounting for guns, termed a traversing platform, by means of which the gun may be made to pivot on any centre, and be directed with great ease in various directions. Traversing platforms are principally used for heavy guns, 68-pounders, and 8- and 10-inch guns on board ships and in casemates.

Mortars are placed upon solid beds of wood or iron, which are made as heavy as is consistent with the power of transporting them from place to place, and for the sake of obtaining steadiness when the piece is fired. The larger kinds of mortars and their beds are removed on platform carriages. Sea mortar-beds are made of strong timber; they have a hole in the middle for receiving the iron bolt on which the bed turns round, and they are placed on strong wooden frames fixed in the vessels by which they are carried.

The number of horses employed in the British service to draw artillery of the different natures is as follows:—For an 18-pounder or an 8-inch howitzer, from 8 to 10 horses. For a 12-pounder, 9-pounder, a heavy 6-pounder, or a 24-pounder howitzer, from 6 to 8 horses. For a light 6-pounder, a heavy 3-pounder, or a 12-pounder howitzer, from 4 to 6 horses. It may be observed here, that 4 horses cannot draw a weight twice as great as that which can be drawn by 2; therefore the number of horses which should be applied to draw weights must be increased in a higher ratio than the weights.

Formerly two 6-pounder guns were attached to each battalion of infantry, but this practice has long been discontinued, and now all the artillery which accompanies an army into the field is formed into batteries or brigades, each invariably consisting of six pieces. The brigades of foot-artillery consist either of five medium 12-pounders and a 32-pounder howitzer, or five 9-pounders and a 24-pounder howitzer; and a troop of horse-artillery is usually composed of five 9-pounders, 24-pounder howitzer, though they have occasionally been composed of 6-pounders and 12-pounder howitzers.

Six-pounder guns were not much employed with the armies under the Duke of Wellington, as they were found to be inferior in effect to the artillery which the French brought into action during the war; they may, however, be advantageously employed with a corps detached for the purpose of intercepting an enemy's convoy; but it may be observed in general, that field ordnance should be such as may take good effect against troops at the distance of 800 or 1000 yards: 12-pounders, and even 18-pounders, are necessary in the field when it is required to destroy palisades or small intrenchments, to break down bridges, and the like.

The guns hitherto employed in siege trains have been 18- and 24-pounders, and 8- and 10-inch howitzers, though at the siege of Sebastopol 32- and 68-pounders and 8- and 10-inch guns were employed. The mortars are the 8- and 10-inch, and occasionally, as at Sebastopol, the 13-inch mortar and the small Coehorn or $4\frac{2}{5}$-inch mortar.

With respect to the quantity of ordnance which should accompany an army into the field, no precise rule can be given, as the ratio of the number of men to that of the guns in the great armies on foot during the wars of the early part of the century was very various; but, according to General Lespinasse, a division of 12,000 men, including two regiments of cavalry, should be attended by three brigades of horse and three of field artillery: one brigade of each kind is recommended to be always with the division, another of each kind to remain with the general *park* of artillery, and the rest with the depôt in rear of the army.

Long guns have now wholly superseded carronades for the navy, both because their fire is more accurate, and because of their greater range and penetration. For the sake of obtaining a nearly horizontal direction when a ship is rolling, it is a common rule in action to fire when the vessel is nearly upright; but this is said to be subject to some limitation, for it may happen that then the ship is in the trough or hollow of the sea, in which case she will have less command over her enemy than if she were on the summit of a wave: and it is recommended that shot intended to take effect on the hull of an enemy's ship should be discharged while the side engaged is descending towards the water; or if intended to act against the rigging, it should be fired with the rising motion of the side, provided the aim be taken low.

For further information on the subject the reader is referred to Sir H. Douglas's 'Treatise on Naval Gunnery.'

ORE. [MINING.]

OREADES (Ὀρειάδες, from Ὄρος, a mountain), Nymphs who dwelt in mountains, caves, and grottoes; but the nymph of each cave and mountain had a specific name corresponding to that of her dwelling-place. (Pausanias, v. 5, ix. 3, and x. 32; see also Theocritus, 'Id.,' vii. 137.) The Oreades were among the attendants on Artemis. The most celebrated of the Oreades was Echo, who incurred the anger of Hera by engaging her in talk on the mountains whilst Zeus sported with others of the Nymphs. On discovering the trick, Hera deprived her of control over her tongue, so that she became unable to speak till some one else had spoken, and then unable to keep from repeating what was said. Wandering thus, she met and became deeply enamoured of Narcissus, who not requiting her affection, she pined away until nothing remained of her but her voice. (Ovid, Met. iii.)

Under NAIADS and NEREIDS we have spoken of the Nymphs of the fountains and fresh waters and of the sea: we here add a brief account of Nymphs generally, in order to render our notice of the subject more complete.

Nymphs (Νύμφαι, *Nymphæ*) were female deities in the Greek and Roman mythology, who were exceedingly numerous, and were supposed to preside over all parts of the earth. Those who presided over rivers, brooks, and springs, were called *Naiads;* those over mountains, *Oreades;* those over woods and trees, *Dryades* and *Hamadryades;* those over the sea, *Nereids;* those over valleys, *Napææ*, &c. (Homer, 'Il.,' xx. 8.) They were thus associated with all the forms of external nature; and they were the attendants of Hera, Aphrodite, Artemis, and other of the higher goddesses; they are also seen with Apollo; as the nurses of many of the gods, as Zeus, Dionysus, and Pan and along with Dionysus, Pan, and the Satyrs in their dances and revels. Their lives were very long, but they were not immortal. (Paus., x. 31, sec. 2.) They were worshipped in many parts of Greece, and were propitiated by offerings of milk, oil, and honey, and by sacrifices of lambs (Theocr., 'Id.,' v. 53, 149); and temples were also dedicated to them in Italy. (Cic., 'De Nat. Deor.,' iii., 17.) Another class of Nymphs were regarded as the personification of, or as in some way associated with, particular races and localities, as Cyrene, the Dodonides, Nysiades, &c. The Nymphs occur very frequently in ancient art either alone, as attendants on one or other of the superior deities, or in Bacchic dances: they are represented as lovely but somewhat impassive maidens, generally clad in light transparent garments, or partly undraped. We give a cut of a very beautiful statue of one, an attendant on Artemis, now in the Third Græco-Roman Saloon of the British Museum; it was found in 1766, in the Villa Verospi, near the Salarian Gate, Rome.

ORELLIN. A yellow colouring matter found in the seeds of the *Bixa orellana*. It is soluble in water and alcohol, and dyes yellow with an aluminous mordant.

ORGAN (*Ὄργανον*, Gr., *ŏrganum*, Lat., an instrument), the noblest of musical instruments, whether considered in regard to the grandeur and beauty of its sounds, the variety of its powers, or the sacred purposes to which it is usually dedicated. It consists of a vast number of metallic and wooden pipes, divided into different *stops*, the wind being admitted into the pipes from a bellows, and is played on by means of a key-board. The machinery of an organ, which is rather complicated and exceedingly curious, is described in the next article.

Originally the word *organum* had a very extensive meaning, and signified nearly every kind of instrument, for whatever purpose employed. By degrees it was confined to instruments of music; afterwards it was applied only to those of the pneumatic or wind kind; and finally it was exclusively used to designate that "world of sounds" which we call the organ. It can hardly be doubted that this instrument may be traced to *Pan's-pipes*, or the *syrinx*. It must soon have been discovered that the air may be forced into a closed cavity, and then distributed at will to one or more tubes; and, pursuing the contrivance a little further, something like a modern organ was likely to be produced. Indeed, Mersenne, in his 'Harmonie Universelle,' mentions an ancient monument in the Mattei Gardens in Rome, on which appears the representation of a pneumatic organ. It is a small chest placed on a table. In the front is a female figure playing on a number of keys, and on the other side is a man blowing into the box with a pair of bellows exactly like those in present use. In Hawkins's 'History of Music' (i. 403) is an engraving of this, from a copy found among the papers of Haym, the author of a history of ancient medals. St. Augustine, in his Comments on the 56th Psalm, alludes to instruments inflated by bellows. In the same passage he also gives us to understand that *organ* was a generic term, including every species. "Organa," he says, "dicuntur omnia instrumenta musicorum," &c.

The descriptions left us by different authors of the musical instruments of the early part of the middle ages, and the representations of them on several monuments, prove that attempts were made at different periods to improve them. Much thought was expended in discovering the best method of introducing air into the pipes of the organ. For this purpose a fall of water was employed, and also what must be understood to have been steam. William of Malmesbury describes the manner in which the latter was used. He says, "The wind, being forced out by the violence of the hot water, fills the whole cavity of the instrument, which, from several apertures, passing through brass pipes, sends forth musical noises." At length bellows were employed for the purpose, which were either worked by water or by hand. The application of these two powers led to the distinguishing terms *hydraulic* and *pneumatic*, or water-organ and wind-organ, though, in point of fact, the ultimate result was the same in both. The invention of the former, which historians call an *hydraulicon*, is ascribed to Ctesibius of Alexandria, who lived about B.C. 150–120. [CTESIBIUS, in BIOG. DIV.] Vitruvius is the first writer who gives any account of an organ of that kind.

The period when the organ was introduced into the churches of Western Europe is very uncertain. Pope Vitalian is supposed to have been the first to admit the instrument, about the year 670; but the earliest account to be at all relied on of the introduction of the instrument in the West is, that about the year 755 the Greek emperor Copronymus sent one as a present to Pepin, king of France. In the time of Charlemagne, however, organs became common in Europe. That prince had one built at Aix-la-Chapelle, in 812, on a Greek model, which the learned Benedictine, Bedos de Celles, in his vast but useful and excellent work, 'L'Art du Facteur des Orgues' (1766),* considers to have been the first that was furnished with bellows without the use of water.

Before the 10th century organs were not only common in England, but exceeded both in size and compass those of the Continent. St. Dunstan gave one to the abbey of Malmsbury, in the reign of Edgar, Elfeg, bishop of Winchester, obtained one for his cathedral in 951, which was the largest then known. This is described in eight Latin verses by Wolstan, the learned monk of Winchester, in the 10th century, of which Mason, the poet, in his 'Essay on Instrumental Church Music,' gives the following translation:—

> "Twelve pair of bellows, rang'd in stated row,
> Are joined above, and fourteen more below.
> These the full force of seventy men require,
> Who ceaseless toil, and plenteously perspire;
> Each aiding each, till all the wind be prest
> In the close confines of th' incumbent chest,
> On which four hundred pipes in order rise,
> To bellow forth that blast the chest supplies."

The translator adds an explanation by no means unnecessary. "We are not," he says, "I think, to imagine that these stout bellows-blowers kept their bellows in action all the time the organist was playing. I rather think that his performance did not commence till they had filled the chest completely with wind, which he was afterwards to expend by due degrees, as he found occasion."

The organ was at first very rude in its construction, and extremely limited in its means. The keys were four or five inches broad, and must have been struck by the clenched hand, in the manner of the carillons. The pipes were of brass, harsh in sound, and the compass in the 12th century did not exceed a dozen or fifteen notes, and to accompany the plain chant no more were required. About that time half-notes were introduced at Venice, where also the important addition of pedals, or foot-keys, was first made in 1470 by Bernhard, a German, to whose countrymen we owe many improvements of the instrument, though in excellence of finish they have been surpassed by our English builders.

Few particulars are recorded concerning the organs of this country from the Reformation to the time of Charles I. Camden mentions one at Wrexham, and Fuller has been strangely misguided in describing it to have had pipes of gold. It shared the general fate of organs in 1641; and the old York organ, replaced some years back by a new instrument, was one of the very few that escaped the *organoclasts* of those times. At the Restoration it appeared that only four organ-builders of eminence survived, a circumstance which led to the introduction of foreign artists,—of Bernard Schmidt (commonly called *Father Smith*), and his two nephews, with the elder Harris, and his son Renatus. An account of the dispute between these two family parties is amusingly related in Burney's 'Hist.,' ii. 437. Each erected an organ in the Temple Church, as a trial of ability: Blow and Purcell displayed Smith's, and Mons. Lully (not the great composer) that of the Harrises. The Lord Chancellor Jeffries at length decided in favour of Smith. The principal organs of the latter are - the Temple; Christ-church and St. Mary's, Oxford; Trinity College, Cambridge; St. Margaret's, Westminster; St. Clement's Danes; Southwell Minster; Trinity Church, Hull; and St. Paul's Cathedral. Harris's organ, after being rejected by the Templars, was divided; part was erected in St. Andrew's, Holborn, and part in Christ-church, Dublin. This last portion was afterwards removed to Wolverhampton. His other principal instruments are those at St. Mary-Axe, St. Bride's, St. Lawrence (Cheapside), and Doncaster. He, however, from some unexplained cause, was commissioned to make twice as many organs as his competitor. The 'Spectator,' No. 552, says that he was ambitious of building an organ for the metropolitan cathedral. We have, however, no reason to regret that his wish was not gratified.

To these celebrated mechanicians succeeded Schreider, Smith's son-in-law, who built the organ in Westminster Abbey, and that at St. Martin's-in-the-Fields, the latter a present from George I. as churchwarden; Snetzler, Byfield, &c.; and at a later period, Green, Avery (who most successfully imitated Smith); Gray, Elliot. &c.

---

* A copious work on the Organ by M. Hamel, chiefly compiled from that of Celles, has been published in the 'Encyclopédie Roret.' It is in three small volumes, together with an Atlas, containing nearly 1000 figures.

The tone of the pipes of the old builders—depending on what is technically called the *voicing*—has never been excelled by later makers; but in point of *touch*, and mechanism generally, the moderns are much superior to their predecessors. In mechanical skill and delicate finishing the English organ-builders far surpass their Continental rivals, while in tone they at least equal them; but the costliness of our materials and high rate of wages render the organs of this country much more expensive than those of Germany and France. It has been truly observed. that "notwithstanding the imposing enumeration of so many stops, the large organs of the Continent are inferior in the choice and variety of them to the best English instruments;" a part being, in fact, but half-stops, and several only absurd imitations of other musical instruments. and rarely. if ever, used by scientific organists.

The following is a list of some of the largest and most celebrated foreign organs, from Crosse's 'Account of the York Festival,' 1823, "collected," he says, "from many sources, and enriched with some additions communicated by the Rev. C. I. Latrobe":—

	Stops.	Pipes.
Seville cathedral	100	5300
Goerlitz, in Upper Lusatia	82	3270
Hamburg, St. Michael's	67	
(9 pipes of 16 feet, and 3 of 32)		
Amsterdam, the old church	64	
Weingarten, a Benedictine monastery in Suabia	60	6666
(7 pipes are of 16 feet, and 3 of 32)		
Tours cathedral	60	
Haarlem	60	5000 nearly,
(8 of these pipes are 16 feet, and 2 of 32; the greatest diameter being 15 inches. It is 108 feet high, and 50 broad.)		
Alost	58	
Berlin, St. Peter's	50	
Vienna, St. Michael's	40	
Rome, St. John Lateran	36	
Baltimore, in America	36	2213

Mr. (afterwards Sir John) Barrow, in his 'Tour' (1830), mentions a new organ erected in the church of St. Lawrence, in Rotterdam, containing 5500 pipes, which, according to his calculation, is 150 feet in height.

Our English church-organs are numerous, and generally well toned. Though we have none containing so many nominal stops as a few on the Continent can boast, yet we possess some which, in regard to the greater calibre of the pipes, and power of every kind. surpass any foreign instrument. Chief among these are the new organ in York Minster, and that in the town-hall of Birmingham.

The York organ, built by Elliot and Hill, which has lately been enlarged and improved, contained 56 stops all through, besides 6 copula stops The number of pipes was 4200. The largest metal pipe was 32 feet in length and 20 inches in diameter; the largest wooden pipe was 27 feet long, 3 wide, and 2½ deep. This, the builder boasted, would contain 12 pipes and 2 gallons of wine. Both pipes gave C, three octaves below the second space in the base. It had three rows of keys, and two octaves and one-third of pedals. The width of this instrument was 70 feet, and its height in proportion. The old York organ, burnt in 1829. was the largest in the kingdom; it had 3254 pipes distributed among 52 stops.

The Birmingham organ, built by Hill, and completed in 1836, is, as regards size and power, the rival of that at York, though the latter is superior in both, but not in quality. This is 35 feet wide, 15 deep, and 45 high. The swell-box alone is the size of a moderately large church-organ. It has 40 real stops, about 3000 pipes, 4 rows of keys, and 2 octaves and one-third of pedals. The largest metal pipe is 35 feet long, and 21 inches in diameter, formed, as all the metal pipes in this instrument are, of zinc only. The weight of the whole is about 40 tons.

The old organ in St. Paul's cathedral contains 1797 pipes, divided into 28 stops; 3 rows of keys, 2 octaves of pedals, and the largest pipe is 22 inches in diameter. That in Westminster Abbey has 28 stops, and 1524 pipes; 3 rows of keys, and double diapasons for the pedals. At Exeter is an organ, built by John Loosemore, in 1666; its largest pipes are 15 inches in diameter. The organ at Lynn, made by Snetzler, has 30 stops, and among them is a *dulciana*, there first introduced. Green built the organs at Canterbury, Windsor, Lichfield, and Salisbury. That in King's College chapel, Cambridge, was built by Avery. The organ at Yarmouth, erected in 1740, has 29 stops. St Peter's, at Leeds, contains the same number, with 3 rows of keys, built by Messrs. Greenwood, of that place. The new church of St. Luke, Chelsea, has been provided with an organ, made by Nicholls, containing 38 stops and 1576 pipes. The organ of St Sepulchre, London, contains 2500 pipes, divided into 40 stops; and that at Christ's Hospital, by Hill, is equal in number of pipes and power to any in the metropolis. The large organ in St. Patrick's, Dublin, was presented to that cathedral by queen Elizabeth.

The Great Exhibition of 1851 contained some fine organs, but such was the vastness of the enclosure that they produced very little effect, except in their immediate vicinity. One of these organs (by Willis), altered and enlarged, went afterwards to Liverpool. Another large organ, by Hill, was exhibited at the Panopticon in Leicester Square, but on the breaking up of that establishment it was transferred to St. Paul's Cathedral, London, to meet the altered circumstances under which divine service is now at certain periods conducted in the nave of that building. The organ recently built for Ely Cathedral is a fine instrument. It would, however, be quite impossible, within moderate limits, to do justice, even by a bare enumeration of instruments, to the organ builders of this country, so large has been the demand made on them of late years.

The *Barrel-Organ* is an instrument by which most of the effects of a small keyed-organ are produced by certain machinery. Instead of keys for the fingers, the keys, if so they may be called, are inside the organ, and acted on by means of a cylinder, or barrel, *pinned*, or studded in a particular and singularly curious manner. This barrel is made to revolve by a winch, and in those of an expensive kind by wheel-work moved by a spring.

The Apollonicon and the barrel-organ are described elsewhere. [APOLLONICON.]

ORGAN, CONSTRUCTION OF. We have on record several kinds of organs—the *Hydraulic*, the *Pneumatic*, the *Barrel*, and the *Finger* or *Church* organ.

Of the hydraulic organ we know little beyond its having been operated on in some way by water: it may have resembled the *clepsydra*, or water-clock, which chimed at certain hours; but as the passage of water through the pipes would not produce musical sounds, it is probable that water was employed as a moving power. Indeed, the plan of using water-power to work the bellows of an organ or harmonium has lately been revived, and the water engine may now be considered as an essential feature of an instrument which requires so large a supply of wind. The pneumatic organ, whether more or less ancient than the hydraulic, was certainly the parent of the present finger-organ; but it was so decidedly rude in its construction, that it must always be considered as a distinct instrument. The barrel-organ is a machine with little variety and no expression; it nevertheless contains many clever contrivances, and is daily receiving improvements. The present finger-organ is the largest and noblest of all musical instruments; its power is that of a full band, and for delicacy and sweetness of tone it is unrivalled.

In such an organ there are several thousand pipes, with arrangements for enabling the organist to make any single pipe of the number speak without disturbing any of the others. Now to do this there must be, 1, a bellows for supplying condensed air or *wind*; 2, a channel for conveying it to the pipe in question; 3, a valve, or some contrivance for admitting wind to this pipe when it is required to speak, and for cutting off the supply when it is required to be silent; 4, a lever for opening or shutting this valve. There are many other contrivances for producing variety of effect, loudness or softness, qualities of tone resembling various musical instruments, &c.

The sets of pipes in an organ are called *stops*; the corresponding notes of the different stops may agree in pitch, that is, they may be in unison; or they may produce a chord or an octave above. They differ however in quality of tone. Each stop is, in fact, a range of pipes of the same quality of tone, and extending throughout the compass of the instrument. When a certain stop is drawn, the keys will play throughout on pipes of that character of which the stop consists.

A complete and full finger organ should have *three sets of keys*, and at least *two octaves of pedals*.

The first set of keys takes the *swell*, the second the *great organ*, and the third the *choir*. The compass, as well as the size of organs, must depend upon circumstances. The German scale or compass is C C to F in alt; the English formerly descended to G below, but are now generally constructed on the German principle; the pedal organ taking the notes down to C C C, which, for duet and solo performances, is certainly the best. A good swell is always important to an organ, and we should recommend C C to F in alt as the compass to be preferred. The compass of the choir is generally the same as that of the great organ. These several parts, or organs, when brought together by stops, called *couplers*, give to the keys of the *great* organ the command of *every pipe in the instrument*, the power and majesty of which are without parallel in instrumental combinations.

Fig. 1 is a section of a large organ, showing the several situations of certain principal parts of the instrument, which, however, are variously placed by different organ-builders. A is the *swell-box*, which is usually made of deal, and the thicker the better, but it certainly should not be less than an inch and a half in thickness; it must be lined with paper or leather to deaden the tone when shut. The front is formed of *Louvre*-boards, all of which are made to move on centres; they must also be an inch and a half thick. The performer opens them by a pedal expressly employed for opening and shutting the swell. This kind of front is what is known by the name *Venetian*. B is the choir *sound-board*, or part in which the pipes of that part of the organ are placed; C is the great organ *sound-board*, which also contains its pipes; D is the *bellows*; E is the *pedal sound-board*; F is one of the front pipes, to which the wind is conveyed by metal tubes, called *conveyances*; G G G are three roller boards, one for each organ; H is a *tracker*, used with *squares* and *centres* to reach distant parts of the action; at I are the *keys;* at K are the *pedals;* L is the seat. The numerous things which are not indicated in this figure must be sought for in *working* drawings, as we cannot and do not pretend to give these matters a practical form.

Fig. 1.

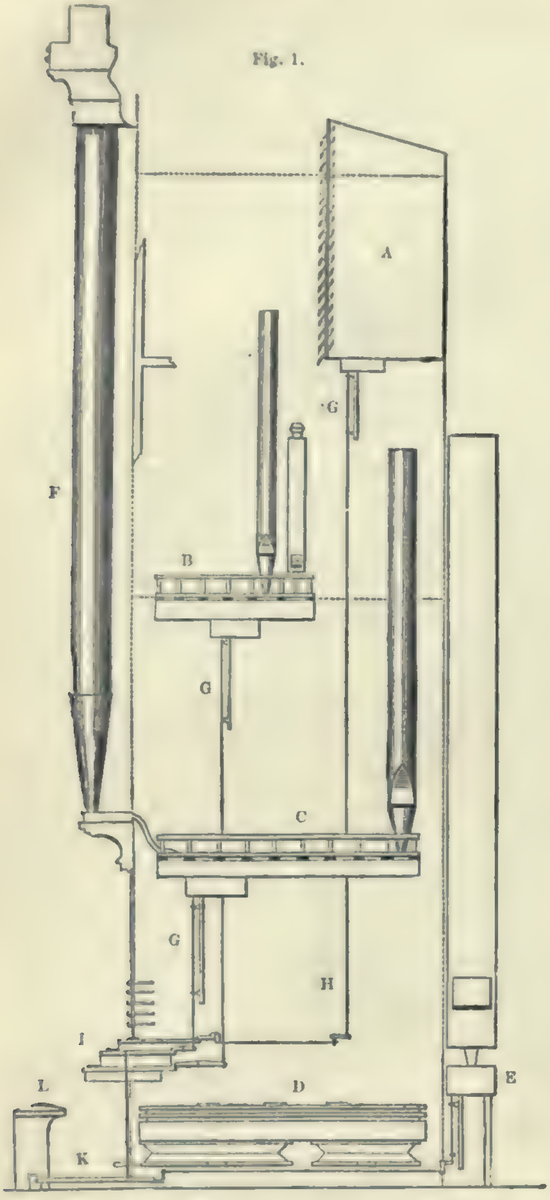

Fig. 2 represents what are called the *horizontal bellows.* A shows the *reservoir;* B, the deep frame through which the wind is taken; C, the part moved in blowing, called the *feeder;* D D, the *registrars,* by which the equal rising of the reservoir is ensured: there are valves inside for receiving and retaining the wind, all of which are differently constructed by different builders.

Fig. 2.

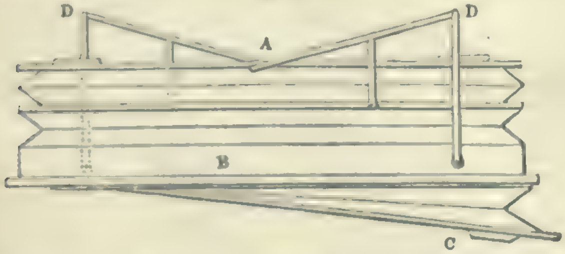

Fig. 3 is a perspective view of a *roller-board;* A A A, the board on which the rollers are fixed; B, three *pull-downs,* explained below; C C C, rollers centred at each end into small blocks, in which they move; there are also *arms* to each end, in front, connecting the rollers with the keys and the wind-chest; D, the levers which are connected with the keys and the pull-downs, and are longer or shorter as may be required; they are also *parallel* or *fan-like,* to suit their position.

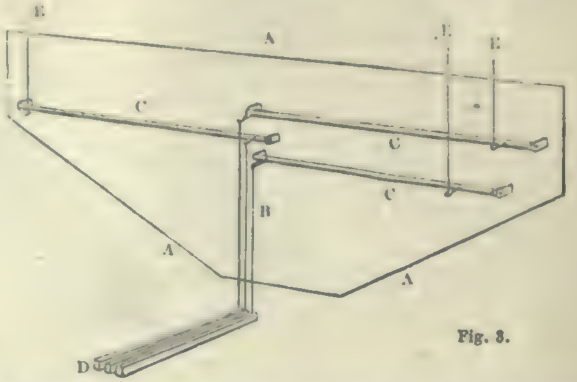

Fig. 3.

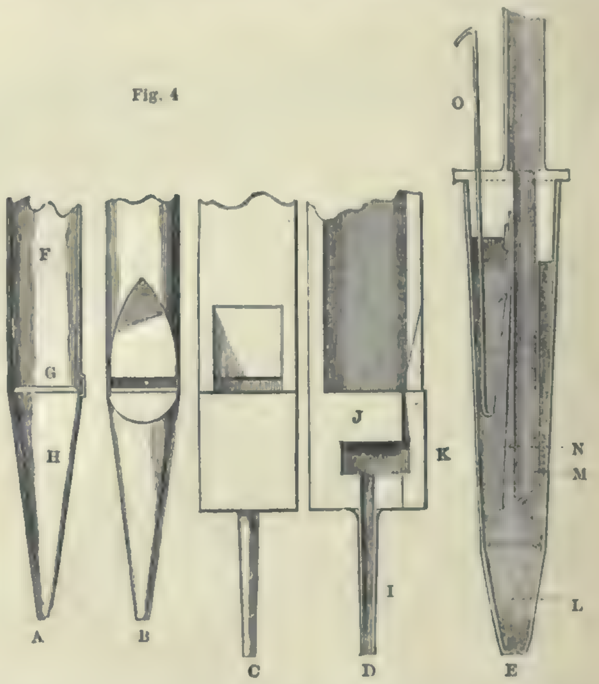
Fig. 4 contains a few examples of pipes. There are two general descriptions of pipe, namely, the *mouth, flute,* or *flue* pipe, and the *reed* pipe, each containing several different species. Mouth pipes have a mouth and lips like a flageolet; they may be of wood or metal, and the upper extremity may be open or closed by means of a plug, called a *tompion,* the effect of which is to lower the pitch a whole octave. The lower end is also closed with the exception of a narrow slit, which, in the pipes C and D, meeting a portion of the front wall bevelled to a sharp edge, forms what is called the *upper lip,* or *wind cutter.* The foot of the pipe fits into the apparatus or chest which supplies the pipes with wind. The blast from the narrow slit impinging on the upper lip is thrown into vibration, which it imparts to the whole column of air in the pipe, the result of which is a musical note, depending for its pitch on the length of the column thus set in motion. The voicing of the pipe is performed by paring away the upper lip; the upper part of the block is also toothed, so as to divide the plate of wind, or it would otherwise begin the note with a chirping noise. There are other precautions to be attended to, such as the width of the mouth. In metal mouth pipes, A B, the plate of wind is formed by the edge of the languette, by leaving a thin slit between the end of the languette and the lip. A is a metal open pipe; F, the sounding part; G, the part called the *languette,* and H, the *foot;* B is the same pipe, showing the *mouth* and the flattened part for *voicing;* C is a front view of a *stopped diapason* pipe; D is a section showing the arrangement of its construction; I is the *foot;* J is the *block,* and K is the *cap.* E is a section of the voice part of a *reed* pipe; L, the *foot;* M, the *mouth-piece;* N, the *reed;* and O, the *tuning-spring.* The pipe itself is made of a metal alloy of tin and lead; the *reed* is brass, and the *spring* is soft steel wire, about a tenth of an inch in diameter. By pushing down or drawing up the tuning-wire, the free part of the tongue is made shorter or longer. The tube above the cone or foot is variously shaped, and on it depends the *quality* of tone in reed pipes, the *pitch* being due

Fig. 4



to the length, thickness, and elasticity of the tongue. This form of reed pipe is the basis of all the others, their differences being more in shape than in principle. There is however a distinction between the *free* reed and the *beating* reed, as explained below. [See also HARMONIUM.] When speaking of the lengths of pipes, it is generally with reference to *tuning* or *pitch* C, which is one foot long; and *all* C's *below are doubled* as we go from 1 to 2, 2 to 4, 4 to 8, 8 to 16, and 16 to 32; the last, although little used in this country, gives the highest rank to organs.

SPEAKING LENGTHS AND SEMIDIAMETERS OF STOPS.

	Open Diapason,	Principal, and	Fifteenth.

⊙

Centre to the above Semidiameters, which are real dimensions. This centre must be ½ an inch below the first dot.

This Table shows the relative lengths and diameters of the open *diapason*, the *principal*, and the *fifteenth stops*, as high as C above middle C.

Quints, *twelfths*, and *sesquialteras*, all take the sizes and lengths of their proper tones in the open diapason. *Trumpet* and *Oboe stops*, being what are called *unison stops*, also take their lengths from the *open diapason*. The *clarion*, an octave stop, is measured by the *principal*. The bells of all *reed-pipes* should be as large as their places in the organ will admit of.

Middle C in the *dulciana* is an inch and a quarter in diameter, and about two feet two inches long. A large size stop-diapason is seldom pure and musical. An inch and eighth wide and an inch and three-eighths deep, with thirteen inches in length, is a good scale for a *middle* C *stop-diapason pipe* in wood. Scales may be taken of larger or smaller dimensions, if desired, in which case the larger must be shorter and the smaller must be longer. Where stops are repeated, two or three of the same name, it is thought better to have them of different diameters, from an opinion that two or more unison-pipes of the same diameter affect the ear only as one pipe. There is something in this opinion, but how much we will not venture to determine.

Fig. 5 is a section of a *sound-board*, showing some part of the mechanism. A is the *rack-board*, by which the pipes are held in upright position; B shows the ends of the slides; C, that part of the sound-board which contains the *channels* for conveying the wind to the pipes; D, the pallet or valve which is opened by the finger of the organist, through the *key*, the *lever*, the *pull-down*, and the *roller* (see *Fig.* 7); E is the spring which keeps the pallet in its place when not in use; F is the *pull-down*, having a small screw and a leather button at one end, and a piece of hard bell-wire at the other; the former is fixed to the *lever*, and the latter to the *arm* of the *roller*; G is merely one end of the roller-board.

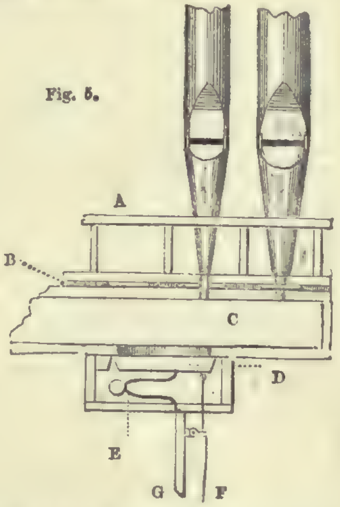

Fig. 5.

Fig. 6 represents a *draw-stop*, a *trundle*, and a *lever*, all of which are used by the organist in changing a stop or slide; A is the *draw-stop*; B is the *trundle*; C is the *lever*; D is the *slide*. The draw-stop is linked to the trundle at E, the trundle is linked to the lever at F, and the lever is fitted to the slide at G. Their centres are all at H. In connection with the above, there are also pedals called *composition pedals*, three, four, and five to an organ.

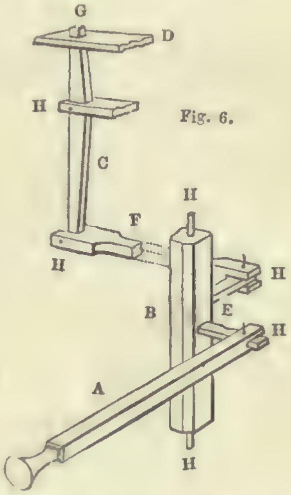

Fig. 6.

Fig. 7 represents certain small parts of the action. A is the wire by which the pallet is opened; B is the pull-down attached to it; C is the pallet-end of the roller, with its fixing to the board; D is an end view

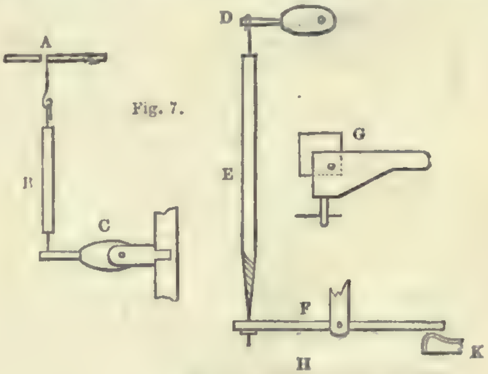

Fig. 7.

of a roller, with a pull-down and lever, all in their relative connection; E is the pull-down, and F is the lever, to which the key follows; G is a common form of a *square* or *centre*, by which the trackers are united. *Trackers* are pieces of pine wood, ⅜ of an inch wide, and from ⅛ to a ¼ thick; they are of different lengths, and may be used to any extent. The Birmingham organ is said to have four miles and a half of trackers in it. In the cathedral organ at Canterbury, they are employed to remove the keys to a distance from the instrument, which is done to the extent of ninety feet. H is the form of a pedal-key; I is the *sharp*, and H is the *natural*. The length is about two feet; the distance from centre to centre of each pedal is two inches and a half.

Fig. 8 represents an *anemometer*, or wind-gauge. It is a glass tube, bent as in the figure: the dark part is supposed to be water. A is the place to which it is applied in the organ, which is generally the hole for the pipe used as the pitch A or C. The pressure of the wind at B drives the water up to C, and the measure of their difference is what is called the *wind*. Some organs have more, and some less; two inches and a half is the common measure.

Fig. 8.

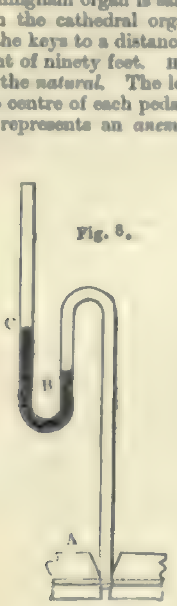

Fig. 9.

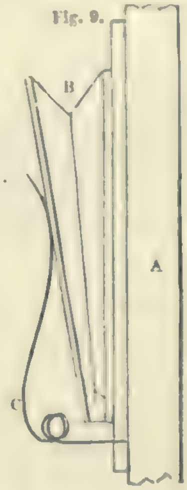

Fig. 9, represents a percussion valve. It may be said to be a small bellows pressed by a spring. A is the wind-trunk, to which it is fixed; B is the valve itself, and C is the spring. The use of this part of an organ is to steady the wind, which is sometimes disturbed by sudden transitions or very rapid performance: the spring of the valve is regulated so as to give way on such occasions and to moderate their effects.

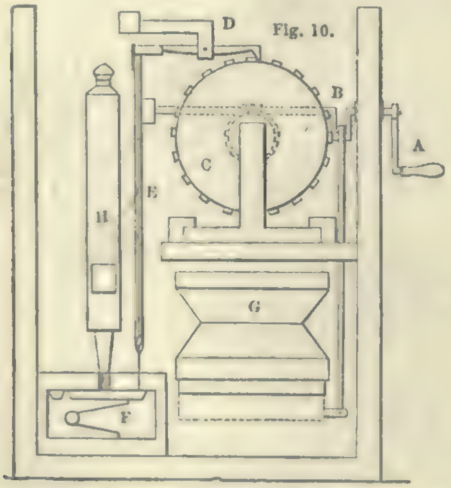
Fig. 10 is a section of a common barrel-organ. A is the handle; B the *worm* and *crank*, which move the *barrel* and *bellows*; C is the barrel on which the tunes are set. The setting is effected by brass pins and staples driven into the barrel at proper distances, accordingly as the notes are longer or shorter. D is the key, the rising of which over the pins causes it to press down the sticker (E) into the wind-chest (F), and thus to open the pallet for the wind to enter the pipe above; G is the bellows; H, a stop-diapason pipe. This diagram shows only one barrel, which is the common plan, but Messrs. Gray and Co. have introduced three, by which great risk to the mechanism is avoided and much trouble is saved.

Fig. 10.



The tuning of organs is a subject on which there is much difference of opinion. Some tune from C, on the *unequal temperament*, and throw the imperfections on what is called the *wolf*, or key of four flats. Others tune from A, and adopt the *equal temperament*; this latter certainly has the better reasoning in its form, as it approaches nearer to the human voice, interferes less with the band, and is more agreeable in general modulation. This subject has been minutely handled by some scientific writers, who have given themselves the trouble of what may be called *splitting* octaves into *smaller intervals*. But the advantages of this minuteness have not yet extended beyond the schemers themselves, for not one of their methods has yet left the cradle of its birth. The Temple organ is said to have 14 sounds in the octave; the Foundling, 16; Hawke's patent, 17; Loeschman has 24, and Liston's enharmonic organ as many as 59, of which 24 are on the keys, and the rest on the pedals and other contrivances. If such schemes were to become general, they would make practical men tremble; but *flat fifths* are still in use notwithstanding the enharmonic divisions, and they have nothing to fear beyond an occasional dispute on the subject.

The numbers and kinds of stops are matters not subject to rule; they vary in almost every organ, and seem more under the command of circumstances, such as space and price, than any other parts of the instrument.

In treating the mechanism of the organ in so general a manner, we shall hardly be expected to point out all the improvements which have been made of late years in its various parts: a few however may be mentioned. Considerable strength both of hand and foot, as well as consummate musical skill, are required in an organist; the expenditure of wind also may vary from a few hundred to many thousand cubic feet per second. With a small expenditure of wind there is a greater elasticity of the air, and consequently a greater pressure against the valves so as to make them more difficult to open. The remedy for this was Mr. Barker's Pneumatic Lever, in which the elasticity of the air itself is made to overcome the resistances which had previously been thrown upon the organist. Mr. Willis has a contrivance for admitting wind to the pipes of the pedal-organ; it is formed by covering the aperture with a piece of leather, fixed at one end, and attached at the other to a wooden roller, so that when the latter is moved by the pedal key, it wraps the leather round it and so uncovers the opening, when the key is released a spring brings the roller back, and by unrolling the leather, again covers the aperture. Mr. Bishop's *Composition Pedals*, for opening and shutting the stops by the foot instead of the hand, are of great value, as is also his *Anti-concussion apparatus* for preventing the pulsation or concussion of air in the wind-chest, when a large number of pipes are made to cease speaking suddenly and a few only are held on. Mr. Willis has also introduced mechanical improvements for producing *crescendo* and *diminuendo* effects, enabling the player to draw or shut off any required number of the stops, one after the other in succession by one continuous movement, in contradistinction to the intermittent or repetition movements. Mr. Holt has introduced the *pneumatic lever*, or valve, to reed-pipes, so that when the wind is admitted it expands and causes a spring or jack tipped with india-rubber to strike the tongue and set it in motion, similar to the contrivance explained under HARMONIUM. The wind then keeps up the vibrations. By this contrivance the reeds may be made of thicker metal, and a fuller, rounder tone be produced. Lorenzi, of Paris, has introduced various novelties. The highly expressive tones of the organ depend principally on a repetition of sounds which succeed each other as the keys are touched. The keys act upon two stops, the first upon one pipe, and the second upon another in unison with it. The sound-board is divided into two parts with double valves, so that those of the first part admit wind to the pipes which are acted on only by the first stop, and those of the other part admit wind to the pipes which are acted on by the other stop. By pressing the key lightly to the first stop, and playing one note only, a soft sweet sound is produced; and by depressing the key entirely, the second stop is brought into action, and greater expression and power are thus attained. In this arrangement there may be a single sound-board in two parts, or two separate sound-boards may be used. The notes of the first part, particularly of the flute, bugle, and trombone stops, are of great delicacy and sweetness; and those of the other part, produced by the second series of stops, are of the greatest power and are occasionally double. The transition from *piano* to *forte* is not perceptible when the second note is commenced, but it is necessary to separate the first from the second part of the sound-board, as also of the pipes by enclosing them in a swell-box. By opening the swell the full power of the notes is obtained, without any violent transposition from piano to forte. The mechanism for effecting this is attached to a pedal, so that it may be disengaged from the keys when required. Another mode of giving expression and increasing the force by vibration or *trembling*, and increasing and decreasing the sound, when applied to the *fono-chromic* organ with two valves, allows the performer gradually to augment the sound to double its usual force, and to diminish it again in the same manner, thus producing effects of a novel and delightful character. In order to obtain this result, an *expansive* bellows is employed; this forms a reservoir, and at the same time (on opening a valve) increases the force of the air nearly twofold. It is divided longitudinally into two parts, the part answering to ordinary bellows occupying three-fifths, the other part two-fifths, so as to make two bellows united. This smaller part communicates with the larger by means of a small valve placed above the hole, by which this second part receives the supply of air. There is also a valve which should remain open, and beside it another valve applied to a hole for the purpose of discharging the air from this part of the bellows. A very simple mechanism is employed for opening this latter discharging valve (no matter of what size the opening may be) and of shutting the other, so as to stop the communication with the other part of the bellows. By means of this mechanism, when the smaller bellows has discharged itself into the greater, the power of the latter is nearly doubled. It is worked by the same pedal which applies the trembling sound, and the same pedal also acts upon the swell-box containing the second series of pipes. These three movements are so arranged, that in depressing lightly the pedal, it acts only upon the mechanism of the trembling sound attached to the pipes acted upon by the first series of stops, and makes that note only vibrate; by depressing the key to the second stop the power of the note is greatly increased, and by then depressing the pedal further the note still increases in power; finally, when the pedal acts upon the mechanism of the expansive bellows, it gives a great volume of sound. The reverse process gradually diminishes the sound, but to reduce it to *pianissimo*, another pedal or lever under the key-board, worked with the knee (and hence called a *genual*), shuts some of the jalousies or lower-boards of the case enclosing the first series of pipes, and by this means the note is further diminished in force. These jalousies are disposed like those for the second series of pipes, but with the difference that in their state of repose they are open.

ORGANIC ANALYSIS is the generic term for a great number of chemical and physical operations, that have for their object the ascertaining of the composition and constitution of all matter that has been formed under the influences existing in animal and vegetable life. It also, of course, includes the similar examination of all derivatives and artificial imitations of the matter referred to.

In illustration of the above definition of organic analysis, let us suppose that we have for examination some well-known fruit, such as a pear. By processes presently to be described, we separate and isolate from it the matter or matters that appeal to the eye, in other words the colouring agent; similarly we obtain the odoriferous principle; then a matter that has no odour, but a distinct and well-defined taste; next we chemically dissect out the framework or skeleton; and finally turn our attention to the great mass of substance with which the framework is filled in. Operations are next undertaken by which we assure ourselves that the bodies thus separated are neither more nor less than what we suspect them to be; uniformity is here the great characteristic. Solid or liquid, the body in question must have a constant specific gravity; taste, odour, touch, must be unvaried; to the eye, alone or aided by the microscope, the appearance of each observable particle must be identical; if a fusible solid, it must have a constant melting point; if a volatile liquid, its boiling point must be unvarying. The next series of operations acquaints us with the number of elementary substances contained in each body under examination, as well as with the exact per centage amounts of those elements. Having now, to a certain extent, a knowledge of the composition of the bodies, we arrive at their probable constitution by a process of analogical reasoning; and this is confirmed or disproved by severally subjecting them to powerful chemical reagents. Possibly the latter cause the substances to be split into two or three bodies of more simple constitution; if so, they each must be passed through the prescribed ordeal. The odoriferous principle, for instance, of the pear has been isolated in a state of purity, and has been found to contain certain constant centesimal amounts of three elements; but on farther chemical examination it breaks up into two compounds, each of which however is found to possess uniform properties, and to have a constant centesimal composition. And now, having individualised and given character to each of the bodies under examination, we probably recognise them as old acquaintances, or possibly take to ourselves the merit of having discovered new ones. Our pear would yield us such bodies as water, starch, lignin, sugar, &c.; the flavouring principle, or essence of pears as we might call it, being found by the latter part of the examination to be a compound of acetic acid and oxide of amyl, or shortly the acetate of amyl. Several of the bodies enumerated may be artificially produced, their identity with the natural products being established by the similarity in their physical and chemical characters, especially as evidenced by their per centage composition.

From what has already been stated, it will be observed that organic analysis is either *proximate* or *ultimate*. The appearance and behaviour of bodies when acted upon by various reagents or tests may, when viewed by an experienced eye, be sufficient to establish their individuality, and their presence and even amount, in the matter originally operated on, may thus be satisfactorily determined: such is proximate organic analysis. But perhaps the bodies in question have no well-marked properties, or are possessed of characteristics not before observed in any known substance; in either case the number of their elementary constituents must be discovered, and the amount of each element ascertained; and such is ultimate organic analysis. Ultimate analysis also forms, as it were, the court of appeal from the decisions arrived at in proximate analysis.

Organic analysis and inorganic analysis are conventional divisions of chemical analysis. Each is subdivided into proximate and ultimate, and either one of the four classes is qualitative or quantitative in the sense of those words already alluded to under CHEMICAL ANALYSIS. The line of demarcation that separates these divisions is not very sharp; many bodies being found in animals and vegetables in a state not distinguishable from that in which they exist in the inorganic kingdom; such, of course, demand inorganic analytical treatment. Other bodies require modifications of organic or inorganic analysis, according to the nature of the substances with which they are associated, and from which they are to be isolated. The broad principles, however, of inorganic and organic analysis are pretty well defined, and the difference between them easy of practical recognition. While, on the one hand, inorganic analysis comprehends the manipulatory processes connected with the examination of metals and their salts: organic analysis, on the other hand, includes only operations which aid in discovering and investigating the apparently innumerable series of compounds formed by the union, in various ways, of the four elements—carbon, oxygen, hydrogen, and nitrogen.

Proximate Organic Analysis.

This is by far the more difficult branch of organic analysis. An animal or vegetable substance usually contains a much greater number of proximate principles than the most complex mineral; these principles have been built up by the agency of that mysterious aggregation of influences sometimes, though very unphilosophically, termed vital force; and, inasmuch as organic matter is necessarily only examined after those influences have been withdrawn, it follows that there is a constant tendency, as in all dead animal and vegetable matter, to return to its original more simple and stable condition. In addition to this source of complication, the bodies in question being held together by such weak affinities, are not only more readily acted upon and altered by the agents employed by the chemist to separate them, but very frequently act upon each other; so that, indeed, the perfect proximate analysis of organic matter is, in the present state of our knowledge, an impossibility; and the various published processes, professing to give a means of arriving at that desirable end, must be looked upon as being merely provisional. We are, however, able to isolate very many proximate principles, and it is quite admissible to include in an analysis such substances as "extractive matter," "balsamic matter," "resinous matter," "ethereal, alcoholic, aqueous, or alkaline extractive," &c., provided always that it be remembered that such names are only provisional, and that in future times, as in times gone by, an increasing number of definite principles will probably crop out from such collective substances, and finally their names be altogether expunged from proximate organic analysis.

We are indebted to Rochleder for the latest improvements in this department of chemistry. The process may shortly be stated as follows. (For further details see 'Pharmaceutical Journal' for 1860.)

The organic matter is first mechanically disintegrated. The more points of contact presented by a solid to the solvent action of a liquid, the better it is; so that comminution cannot well be carried too far. Often a certain degree of moisture renders the material tenacious and elastic, so that it is difficult of pulverisation; in that case a careful drying suffices to bring it into a pulverisable condition. Sometimes oily bodies cause the same kind of tenacity, and then expression of the cold or slightly warmed material will expedite matters. In other cases appropriate solvents may be used for the removal of bodies causing tenacity, and disintegration thus facilitated. If pulverisation cannot be accomplished by stamping or rubbing, recourse may be had to rasping, slicing, &c. Obviously much will depend upon the characteristic properties of the substance operated upon, so that no general rule can be laid down; at the same time, however, the above hints may give an idea of the methods to be adopted.

The material in a fine state of division is now divided into several portions, and each treated with a solvent, in order to obtain a number of extracts, which are to be submitted to farther examination.

One portion is boiled with water in a distillatory apparatus, by which a decoction and a distillate are obtained; the former will contain non-volatile constituents soluble in water, the latter volatile matters only. Another portion is treated with cold water, in order to dissolve out such matters as would be coagulated by the hot water. A third portion is heated in water acidulated with sulphuric acid, organic acids being thus set free and dissolved, and sulphates of alkaloids also extracted. The fourth operation is digestion in water rendered alkaline by ammonia, and for this the residue of the first operation may be employed. A fifth portion is subjected to the solvent action of alcohol, either cold, hot, strong, or weak, according to the nature of the material under examination; fats, oils, resins, and many bodies insoluble in water being thereby dissolved. The sixth process consists in treating with ether, which much resembles alcohol in its powers of solution, but differs in its action upon free fatty acids, and one or two other important bodies.

In addition to the above solvents, others are employed for special operations, as circumstances seem to indicate. Thus the alcohol or ether may be used in an acid or alkaline condition, as described for water; and benzole, chloroform, bisulphide of carbon, and similar liquids, may also be pressed into service under certain circumstances. As before stated, much must depend upon the knowledge, judgment, and observation of the experimenter.

The treatment of the several liquid extracts obtained as above described is the next point for consideration; but here the field of experiment becomes so greatly enlarged that anything like a detailed description of it would lead us far beyond the limits of the present article. Suffice it to say, that fractional distillation, fractional crystallisation, and fractional precipitation form the bases of operation adopted in the separation and isolation of organic proximate principles.

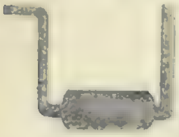
The examination of the residue after an organic material has been successively subjected to the action of the above liquids, is not a matter of very great difficulty, inasmuch as it can only consist of such substances as lignin and cellulose. Nor is it difficult to extract one proximate principle only from organic material, experience of the properties of similar principles here guiding to the most proper method.

The physical and chemical properties that should characterise an organic proximate principle have already been alluded to at the commencement of this article; it now, therefore, only remains to consider

Ultimate Organic Analysis.

From what has been stated, it is evident that this operation mainly consists in the determination of the quantities of carbon, hydrogen, oxygen, and nitrogen contained in any organic substance. Chlorine, bromine, iodine, sulphur, and phosphorus are comparatively very rarely met with; they are estimated in the manner described under each of those elements, or by some slight modification of the methods there given.

The first point to be attended to in an organic analysis, or combustion, as it is practically termed, is the removal of hygroscopic water—the removal of that moisture which most bodies absorb by mere contact with the atmosphere. This may be done in several ways; a very good one consists in placing the body over a surface of oil of vitriol under the receiver of an air-pump and exhausting, when complete desiccation speedily takes place. This process has the advantage of not requiring the application of heat, sometimes a point of great importance. Substances that bear a temperature of 212° Fahr. are dried either in a water oven, or are placed in a curved tube of the annexed form, which is introduced into boiling water and dry air drawn through it. Sometimes mere exposure to dried air at common temperatures is sufficient to desiccate a substance.



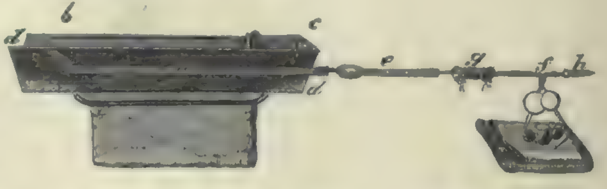
The next step in the process is the accurate weighing of the material. For this purpose the latter is usually inclosed in a small tube, and a balance employed that will indicate $\frac{1}{500}$th of a grain.

The following are the principles involved in the actual analysis:—First, of compounds containing *carbon*, *oxygen*, and *hydrogen*; for nitrogen must be estimated by a separate operation. It is well known that when coal or wood, or anything containing the three elements alluded to, is burned, the carbon takes up oxygen from the air and passes off under the form of carbonic acid, while the hydrogen combines with the quantity of oxygen requisite to form water and passes off as steam. Further, it is also well known that these combinations take place in fixed and unvarying proportions; that six parts of carbon always combine with sixteen of oxygen to form carbonic acid; and that one part of hydrogen always combines with eight parts of oxygen to form water. On these facts, then, is founded the process about to be described; for, obviously, if a weighed quantity of the wood, coal, &c., were taken, and the whole of the carbonic acid and water formed could be collected and weighed, we should be in possession of all the data required for finding the amounts of carbon, hydrogen, and oxygen originally present. The total amount of carbonic acid divided by 22 and then multiplied by 6, would give the quantity of carbon; the total amount of water divided by 9 would show the quantity of hydrogen; and the difference between the combined weights of the carbon and hydrogen, and the weight of the original substance, would give the quantity of oxygen.

The burning of the substance must be perfect; there must be no production of compounds intermediate between the original substance on the one hand, and the carbonic acid and water on the other. That the oxygen of the air is insufficient for this purpose is evident, when we remember that smoke is nearly always produced under such circumstances, and smoke is partly composed of those intermediate bodies, the production of which it is indispensable to avoid. The desired burning agent must, then, be one that will so readily yield its oxygen to organic matter at an elevated temperature, as to ensure complete oxidation of the substance to carbonic acid and water; at the same time it must be itself unalterable by the high heat employed. These apparently somewhat antagonistic properties are possessed by the black anhydrous oxide of copper. [COPPER.] About four or five grains of the powdered and dried substance are introduced into a tube (*a*, *fig.* 1) made of very infusible glass, about 15 to 20 inches long, nearly half an inch in diameter, drawn out to a point at one end (*b*, *fig.* 1), and previously about one-third filled up with oxide of copper that has been dried by igniting to redness and allowing to cool in a well-closed, long, narrow bottle: a little more oxide of copper is then poured in, and the substance well mixed with the oxide by means of a wire twisted at one end into a corkscrew shape; more oxide is again introduced, the wire passed once or twice through it to wash off adhering substance, and the tube finally filled up with oxide to within two inches of its open extremity. On heating this tube and its contents to redness, first near its open end (*c*, *fig.* 1), and then gradually throughout its whole length, the organic matter is thoroughly burnt into carbonic acid and water, the manner of separating and collecting which will presently be described.

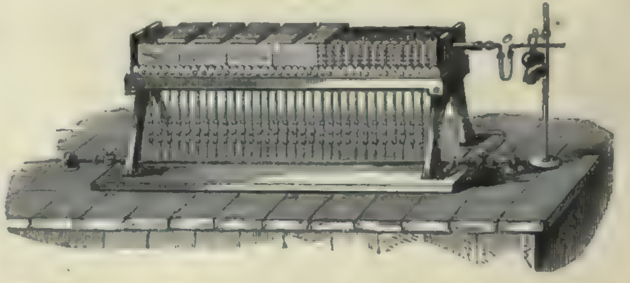
With regard to the best material for heating the tube, much must depend upon circumstances. Till within the last few years charcoal has been the fuel almost always employed, some pieces of which are made red-hot in a furnace, and then placed, a few at a time, first round the anterior part of the tube (*c*, *fig.* 1), the latter being supported on sheet-iron crosspieces in the sheet-iron trough, *d d*, represented in the accompanying drawing.

Fig. 1.



The combustion of charcoal, however, occasions a troublesome amount of dust, and, since the introduction of gas into laboratories, many furnaces have been contrived by means of which the glass tubes may be gradually and regularly heated with that fuel. The latest improvement in this respect is by Dr. Hofmann, the general arrangement of whose furnace is seen in *fig.* 2.

Fig. 2.



In this apparatus the combustion of the gas is effected by means of a number of perforated clay burners, so grouped as to form a channel for the combustion tube, a system of stop-cocks permitting to confine the heat to any special place in which it may be required at the time.

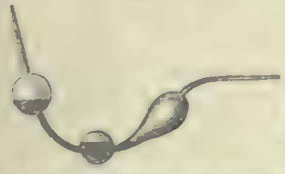
The arrangement by which the water and carbonic acid, formed during the operation from the organic substance, are collected, is very simple. A small glass tube, straight, as seen at *e*, *fig.* 1, or bent to the shape of the letter U, and having a bulb attached, as seen at *e*, *fig.* 2, is filled with pieces of fused chloride of calcium, and firmly fixed by a cork, or solid india-rubber plug, into the glass combustion tube. Immediately at the opposite extremity of the chloride of calcium tube a piece of apparatus, known as 'Liebig's potash bulbs' (*f*, *fig.* 1), is attached by a piece of india-rubber tubing (*g*). The vapour of water and carbonic acid evolved from the tube are thus thoroughly absorbed, the former by the chloride of calcium, and the latter by a strong solution of caustic potash previously placed in the bulbs. The whole length of the tube having been brought to a red heat, and there maintained till no more bubbles of gas pass into the potash, the charcoal is removed from the extremity, the little point *b* broken off, and air cautiously drawn through the whole arrangement by aspiration, with a piece of india-rubber tubing attached to the potash bulbs. In this last operation loss may be occasioned by the air carrying a little vapour of water away from the potash solution, and hence the use of the little tube *h*, which contains a short stick of solid hydrate of potash. In place of driving out the residual vapour of water and carbonic acid by air, a few fragments of chlorate of potash may be placed in the posterior extremity of the tube; and on heating this at the close of the operation, evolution of oxygen takes place, and effects the desired object. The use of chlorate of potash here is attended with two or three advantages, but it is liable to be decomposed so rapidly as to blow some of the solution of potash altogether out of the bulbs. Another and greater modification of the process consists in having a considerable elongation of the tube in the place of the little capillary extremity above described: into this open end a little platinum or porcelain boat, containing the organic substance to be analysed, can be placed, and a stream of pure and dry air or oxygen passed over it. On then gradually heating the glass tube in the neighbourhood of the boat, the substance burns as it would do in air; but the products of combustion pass on over the ignited oxide of copper, and are collected respectively in the chloride of calcium tube and potash bulbs. At the same time any inorganic, non-volatile matter present in the organic substance remains in the boat as ash, and may readily be removed and examined.

Volatile liquids may be burnt in either of the above modifications of combustion tube, but are first inclosed in little bulbs having thin necks that can easily be broken.

With substances not readily burnt, chromate of lead is sometimes used in the place of oxide of copper.

Nitrogen may generally be detected in an organic body by the odour of ammonia which is evolved when a little of the substance is heated in a test-tube with hydrate of potash. It is estimated on the same principle by the following arrangement of apparatus. A combustion-tube drawn out to a point, as already described, is charged with soda-lime in the place of oxide of copper. Soda-lime is made by slaking lime with strong solution of caustic soda, evaporating to dryness, and heating to redness. The same precautions are observed as before detailed, but instead of a chloride of calcium tube and potash bulbs, a three-bulbed piece of apparatus, of the annexed form, is attached to the open end of the combustion-tube, and is charged with moderately strong hydrochloric acid. The acid absorbs the ammonia that is evolved on gradually heating the tube to redness; residual ammonia being driven into the acid by a current of air drawn through the whole arrangement in the manner already indicated. If nitrogen be present in an organic substance it is liable, when burnt with oxide of copper, to pass off in the state of acid-oxides absorbable by potash, hence the estimation of carbon and hydrogen must only be proceeded with after a small bundle of copper turnings have been placed just inside the combustion-tube; this, when heated to bright redness, effects the decomposition of the oxides into non-absorbable nitrogen and oxygen.

Fig. 3.



So much for the practical operations connected with ultimate organic analysis. The weights of the chloride of calcium tube and potash-bulbs having been ascertained, both before and after the combustion, a few simple calculations suffice for ascertaining the percentage amounts of the elements present. These calculations will perhaps be most easily described by an illustration. Suppose that sugar were the substance experimented on, then :—

Quantity of sugar taken	4·75	grains.
Potash apparatus—		
After experiment	781·13	„
Before „	773·82	„
Carbonic acid	7·31	„
Chloride of calcium tube—		
After experiment	226·05	grains.
Before „	223·30	„
Water	2·75	„

7·31 grains carbonic acid contain 2·0213 grains of carbon.
2·75 „ water contain ·3056 „ hydrogen.

Or, in one hundred parts—

Carbon	42·55
Hydrogen	6·43
Oxygen (by difference)	51·02
	100·00

The percentage of nitrogen is calculated from somewhat different data. The acid liquid in the bulbs containing chloride of ammonium, formed by the combination of the ammonia with the hydrochloric acid, is placed in a small capsule, bichloride of platinum added to it, the whole evaporated to dryness over a water-bath, the residue washed with a mixture of alcohol and ether, and the insoluble crystals of the double chloride of platinum and ammonium collected upon a tared filter and weighed: 220·52 grains of such crystals contain 14 grains of nitrogen, their weight, therefore, and the amount of the substance operated on being known, the percentage quantity of nitrogen contained in the matter under examination is easily calculated.

To determine the equivalent or combining proportion of an organic compound necessarily forms an important part of the labours of an analyst, and cannot be deduced merely from the data yielded by the operations that have been described. It is, however, ascertained with tolerable ease, if the compound can be made to unite and form a definite salt with some body, the combining proportion of which is already well known. An analytical operation having then shown how much of the well-known body is thus introduced, an easy calculation indicates how much of the organic compound would combine with one equivalent of the other matter, and this number is obviously the combining proportion of the organic compound. This point having been obtained, theoretical considerations and the data obtained from combustion conduct to a formula for the compound submitted to organic analysis.

ORGANIC BASES. Under the definition of the term BASE, the *organic bases*—or the bases derived from animals and vegetables—have been alluded to. The source, preparation, properties, &c., of these *natural* bases or alkaloids are detailed under their respective names, [CINCHONA, ALKALOIDS OF; CONINE; NICOTINE; NUX VOMICA, ALKALOIDS OF; OPIUM, ALKALOIDS OF, &c.] The *artificial* organic bases have not been so fully described, and indeed in most cases only cursorily noticed in the article on the body from which they are derived. The present article will therefore be devoted to a description of the modes of formation and general properties of the artificial organic bases, prefaced by a brief review of the probable constitution of the organic bases generally.

A prominent characteristic of organic bases is the presence of nitrogen; they all contain nitrogen. The nitrogenous principles in animals are, of course, directly or indirectly obtained from vegetables; and the nitrogen in vegetables is known to be derived from ammonia. Nearly all artificial organic bases are actually built up from ammonia; and, moreover, artificially or naturally formed, they all retain the character of basicity, which is the chief chemical property of ammonia. Following then such strong presumptive evidence, chemists have of late years referred the organic bases to the simple typical body ammonia, and have in most cases succeeded in showing how they are constructed upon, or at all events derived from, the type NH_3 (*amines*). Berzelius was the first to suggest that the basic character of the alkaloids was intimately connected with ammonia. To the prophetic sagacity of Liebig, however, are we indebted for the idea that they were derivatives of ammonia; that they were, in fact, amidogen bases or ammonia (NH_2) in which an equivalent of hydrogen is replaced by an electro-positive radical. Following out this idea Wurtz succeeded in obtaining several such bodies; but it is chiefly to the remarkable and laborious investigations of Dr. Hofmann that we are indebted for the very complete knowledge which we possess of this interesting class of organic compounds.

Amines, is a frequent collective title of the organic bases that are derivatives of NH_3. The amines may be :—1. *Monamines*; 2. *Diamines*; 3. *Triamines*; 4. *Tetramines*; or, 5. *Pentamines*, according as they seem to be constructed upon a single, double, triple, quadruple, or quintuple atom of NH_3.

1. *Monamines.* This class is constructed upon a single typical atom of ammonia, namely, $\left.\begin{matrix}H\\H\\H\end{matrix}\right\}N$. *Primary* monamines contain only one of the three atoms of hydrogen (H) replaced by a radical (R); their general formula is therefore $\left.\begin{matrix}R\\H\\H\end{matrix}\right\}N$. *Secondary* monamines contain two atoms of radical, thus, $\left.\begin{matrix}R\\R\\H\end{matrix}\right\}N$; and moreover the radicals may be similar or different ones. Here we get the first glimpse, and a very faint one, too, of the inconceivable numbers of organic bases that possibly exist; for of twenty radicals the first may be occupying the place of one equivalent of hydrogen in a secondary monamine, while each of the remaining nineteen successively occupy the place of the other equivalent of hydrogen, a new organic base being each time produced. Similarly the second of the twenty radicals may be keeping its place, while the remaining eighteen are consecutively introduced, and another batch of bases formed; and thus with only twenty simple radicals nearly two hundred secondary monamine bases may be obtained. But there are many more than twenty radicals, and each successive one would of course introduce a greater number of changes, and produce, therefore, a greater number of compounds than its predecessor. Moreover each simple radical possesses its own chlorine, bromine, iodine, peroxide of nitrogen, &c., derivative, and of course each of these might keep its place in a secondary monamine, while innumerable changes were being rung upon the second radical. Indeed it is useless endeavouring to pursue these calculations farther; we have only got into the second of twelve classes, and already view such a number of organic bases as would defy the powers of the most zealous experimenter to produce and examine. When, again, it is remembered that the next class, the *tertiary* monamines $\left.\begin{matrix}R\\R\\R\end{matrix}\right\}N$ must contain a far greater variety, an indistinct notion can be obtained of the number of changes that may take place in the still higher classes. The general formulæ of the monamines are obviously six :—

$$\underset{a.}{\left.\begin{matrix}R\\H\\H\end{matrix}\right\}N}\qquad\underset{b.}{\left.\begin{matrix}R\\R\\H\end{matrix}\right\}N}\qquad\underset{c.}{\left.\begin{matrix}R\\R\\R\end{matrix}\right\}N}\qquad\underset{d.}{\left.\begin{matrix}R''\\H\end{matrix}\right\}N}\qquad\underset{e.}{\left.\begin{matrix}R''\\R\end{matrix}\right\}N}\qquad\underset{f.}{R'''\}N}$$

a. Primary monamines, sometimes called *amidogen bases*, such as ethylamine $\left.\begin{matrix}C_4H_5\\H\\H\end{matrix}\right\}N$. *b.* Secondary monamines, like diethylamine $\left.\begin{matrix}C_4H_5\\C_4H_5\\H\end{matrix}\right\}N$. *c.* Tertiary monamines, *e.g.* triethylamine $\left.\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right\}N$. *d.* Secondary monomines—or *imidogen bases*, as they have occasionally been termed—containing a diatomic radical (R'') in the place of two equivalents of hydrogen, *e.g.*, conylamine (conine) $\left.\begin{matrix}(C_{16}H_{14})''\\H\end{matrix}\right\}N.$ *e.* Tertiary monamines containing a diatomic radical, as, for instance, methyl-conylamine (methyl-conine) $\left.\begin{matrix}(C_{16}H_{14})''\\C_2H_3\end{matrix}\right\}N.$ *f.* Tertiary monamines containing a tristomic radical (R''') in the place of three equivalents of hydrogen, examples of them are seen in picoline $(C_{12}H_7)'''\}N$, and leucoline $(C_{18}H_7)'''\}N$.

2. *Diamines.* These bodies are formed upon the type of two atoms of ammonia, or diammonia $\left.\begin{matrix}H_2\\H_2\\H_2\end{matrix}\right\}N_2$, or $\left.\begin{matrix}H\,H\\H\,H\\H\,H\end{matrix}\right\}N\,N$. A great number of organic bases belonging to this type have already been formed; not only primary, secondary, and tertiary, but belonging to intermediate divisions, the construction of which will be readily understood on looking over the annexed list of the general formulæ of diamines:—

$$\left.\begin{matrix}RH\\HH\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}RR\\HH\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}RR\\RH\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}RR\\RR\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}RR\\RR\\RH\end{matrix}\right\}NN \quad \left.\begin{matrix}RR\\RR\\RR\end{matrix}\right\}NN$$

$$\left.\begin{matrix}R''\\HH\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\RH\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\RR\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\RR\\RH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\RR\\RR\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\R''\\HH\end{matrix}\right\}NN$$

$$\left.\begin{matrix}R''\\R''\\RH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\R''\\RR\end{matrix}\right\}NN \quad \left.\begin{matrix}R''\\R''\\R''\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\HH\\H\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\RH\\H\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\RR\\H\end{matrix}\right\}NN$$

$$\left.\begin{matrix}R'''\\RR\\R\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\R''\\H\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\R''\\R\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''\\R'''\end{matrix}\right\}NN \quad \left.\begin{matrix}R''''\\HH\end{matrix}\right\}NN \quad \left.\begin{matrix}R''''\\RH\end{matrix}\right\}NN$$

$$\left.\begin{matrix}R''''\\RR\end{matrix}\right\}NN \quad \left.\begin{matrix}R''''\\R''\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''''\\H\end{matrix}\right\}NN \quad \left.\begin{matrix}R'''''\\R\end{matrix}\right\}NN \quad R''''''\}NN$$

The immense number of bodies that may be represented by any one of these general formulæ may perhaps be obscurely imagined on applying, to either of the first half dozen, the remarks made under the head of secondary monamines.

The following list of examples of diamines is given in illustration of the above general formulæ. Some of the latter, however, have no actually-obtained representatives among the organic bases, although the greater number of them have among the organic neutral principles. [AMIDES.]

$$\underbrace{\left.\begin{matrix}(C_2N)H\\(C_{12}H_5)\ (C_{12}H_5)\\H \qquad H\end{matrix}\right\}NN}_{\text{Melaniline.}} \quad \underbrace{\left.\begin{matrix}(C_2N)H\\(C_{12}H_5)\ (C_{12}H_5)\\(C_{12}H_5)H\end{matrix}\right\}NN}_{\text{Cyan-triphenyl-diamine.}} \quad \underbrace{\left.\begin{matrix}(C_2H_3)\ (C_2H_3)\\(C_2H_3)\ (C_4H_3)\\(C_4H_3)\ (C_4H_3)\end{matrix}\right\}NN}_{\text{Trimethyl-trivinyl-diamine (Acetonine ?).}}$$

$$\underbrace{\left.\begin{matrix}(C_2O_2)''\\HH\\HH\end{matrix}\right\}NN}_{\text{Urea.}} \quad \underbrace{\left.\begin{matrix}(C_2O_2)''\\(C_4H_5)H\\H\ H\end{matrix}\right\}NN}_{\text{Ethyl-urea.}} \quad \underbrace{\left.\begin{matrix}(C_2O_2)''\\(C_4H_5)\ (C_6H_5)\\H \qquad H\end{matrix}\right\}NN}_{\text{Ethyl-allyl-urea.}}$$

$$\underbrace{\left.\begin{matrix}(C_2O_2)''\\(C_4H_5)H\\(C_{10}H_{10})''\end{matrix}\right\}NN}_{\text{Ethyl-piperyl-urea.}} \quad \underbrace{\left.\begin{matrix}(C_4H_4)''\\(C_4H_4)''\\(C_{12}H_5)\ (C_{12}H_5)\end{matrix}\right\}NN}_{\text{Diethylene-diphenyl-diamine.}} \quad \underbrace{\left.\begin{matrix}(C_{14}H_6)''\\(C_{14}H_6)''\\(C_{14}H_6)''\end{matrix}\right\}NN}_{\text{Tristilbyl-diamine (Amarine ?).}}$$

$$\underbrace{\left.\begin{matrix}(C_4H_3)'''\\HH\\H\end{matrix}\right\}NN}_{\text{Acetdiamine.}} \quad \underbrace{\left.\begin{matrix}(C_2H)'''\\(C_{12}H_5)\ (C_{12}H_5)\\H\end{matrix}\right\}NN}_{\text{Formyl-diphenyl-diamine.}} \quad \underbrace{\left.\begin{matrix}(C_{10}H_7)'''\\(C_{10}H_7)'''\end{matrix}\right\}NN}_{\text{Dinicotyl-diamine (Conine ?).}}$$

A peculiar class of organic bases designated by the term *phosphamines* seem to be diamines, corresponding in constitution to urea. $\left.\begin{matrix}(C_2S_2)''\\(C_4H_5)\ (C_4H_5)\\(C_4H_5)\ C_{12}H_5\end{matrix}\right\}NP$, is such a body formed by the action of sulpho-cyanide of phenyl upon triethylphosphine. It contains an equivalent of phosphorus in the place of one of nitrogen. This class has at present only few members, but inasmuch as many monamines exist containing not only phosphorus but arsenic and antimony, in the place of nitrogen, it is possible that the NN in diamines may be replaced by PP, As As, Sb Sb, and by NAs, NSb, PAs, PSb, and As Sb the same as by NP, as seen in the formula of the phosphamine just given.

3. *Triamines,* derived from a triple atom of ammonia or triammonia. The same general remarks that have applied to the monamines and diamines apply also to this third class. Although many natural organic bases contain three equivalents of nitrogen, and may be represented as triamines, it is not positively known that they really are so, and at present only two artificial bases possess the triammonic character at all decidedly; they are:—

Melamine (tricyan-triamine) . . . . $\left.\begin{matrix}(C_2N)_3\\H_3\\H_3\end{matrix}\right\}N_3$

and

Cyanethine (triallyl-triamine) . . . . $\left.\begin{matrix}(C_6H_5)'''\\(C_6H_5)'''\\(C_6H_5)'''\end{matrix}\right\}N_3$

4. *Tetramines.*—Theobromine and caffeine contain four equivalents of nitrogen, and may possibly be tetramines. The only well marked artificial one is glycosine (not glycocin), containing the hypothetical tetratomic radical glycyl $(C_4H_2)''''$; its formula is $\left.\begin{matrix}(C_4H_2)''''\\(C_4H_2)''''\\(C_4H_2)''''\end{matrix}\right\}N_4$, and its explanatory name would be triglycyl-tetramine.

5. *Pentamines* have no representatives among the strictly organic bases. Some cobalt bases that have recently been discovered seem to be pentammonic.

Ammoniums.—When ammonia (NH_3) is dissolved in water a solution is obtained having all the characters of the hydrated oxides of the alkali metals, and is by analogy looked upon, therefore, as containing the hydrated oxide of ammonium $\left(NH_4O,\ HO, \text{ or } \left.\begin{matrix}H_4N\\H\end{matrix}\right\}O_2, \text{ or } \left.\begin{matrix}HHHHN\\H\end{matrix}\right\}O_2\right)$. Similarly when the monamines, whose general formulæ have already been given, are dissolved in water, hydrated oxides of organic bases are produced of the general formula $\left.\begin{matrix}RHHHN\\H\end{matrix}\right\}O_2$, or $\left.\begin{matrix}RRHHN\\H\end{matrix}\right\}O_2$, or $\left.\begin{matrix}RRRHN\\H\end{matrix}\right\}O_2$, and having the termination -monium in place of the original -ine. Thus, ethylamine furnishes hydrated oxide of ethylammonium, and di- and tri-ethylamine yield hydrated oxides of di- and tri-ethylammonium. This change of constitution, and therefore of typical expression, is, moreover, warranted by the fact that the fourth equivalent of hydrogen in ammonium may be replaced, and organic bases of the general formula $\left.\begin{matrix}RRRRN\\H\end{matrix}\right\}O_2$ readily produced; such an one is the hydrated oxide of tetrethylammonium $\left.\begin{matrix}(C_4H_5)_4N\\H\end{matrix}\right\}O_2$, and the corresponding compound of methyl-ethyl-amyl-phenyl-ammonium—

$$\left.\begin{matrix}(C_2H_3)\ (C_4H_5)\ (C_{10}H_{11})\ (C_{12}H_5)\ N\\H\end{matrix}\right\}O_2.$$

In the ammoniums, as in the amines, biatomic (R''), teratomic (R'''), and quadratomic (R'''') radicals may replace two, three, or four equivalents of hydrogen respectively. There seem also to be compounds conveniently represented on the ammonium type as ammonium in which hydrogen is replaced by ammonium itself, or rather by a derivative of ammonium, but at present only two organic bases can be thus viewed. Finally, there are good indications of the existence of di-ammonium and tri-ammonium organic bases derived from double and triple atoms of hydrated oxide of ammonium, and resembling the diamine and triamine bases.

Formation of Organic bases.

The modes in which the natural organic bases are formed are not yet ascertained, for all attempts to produce them artificially have hitherto failed. The artificial bases are formed by several processes, which we now propose to notice, including under each a list of the chief bases produced.

First. Direct substitution of organic radicals for the hydrogen in ammonia. This process will be readily understood by the following example. A mixture of strong alcoholic solution of ammonia with iodide of ethyl is hermetically sealed up in a long tube and heated for some hours in a water-bath; combination takes place, and the result is hydriodate of ethylamine $\left(\left.\begin{matrix}C_4H_5\\H\\H\end{matrix}\right\}N,HI\right)$. On distilling the latter with potash, iodide of potassium, water, and *ethylamine* $\left(\left.\begin{matrix}C_4H_5\\H\\H\end{matrix}\right\}N\right)$ are formed. On now going through the same process, but using ethylamine instead of ammonia, *diethylamine* $\left.\begin{matrix}C_4H_5\\C_4H_5\\H\end{matrix}\right\}N$ is obtained. On subjecting diethylamine to the same method we produce *triethylamine* $\left(\left.\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right\}N\right)$. Triethylamine unites directly with iodide of ethyl, and the result is the formation of the iodide of tetrethylammonium $\left.\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right\}N,I=(C_4H_5)_4\,N,I$. On now treating this iodide with freshly-precipitated oxide of silver, iodide of silver is formed, and the *hydrated oxide of tetrethylammonium* set free. The latter body s a powerful base, comparable only with caustic potash or soda. It saponifies oils, precipitates metallic oxides from their salts, is not volatile without decomposition, rapidly absorbs carbonic acid and water from the air, is itself crystalline, and forms crystalline salts with acids, turns red litmus-paper blue, dissolves the cuticle, and, in short, behaves as though it were an inorganic alkali. Ethylamine is a colourless, volatile liquid of sp. gr. 0·696; vapour density, 1·594; soluble in water in all proportions; acts like ammonia upon solutions of metallic salts, but, unlike ammonia, it dissolves recently-precipitated alumina. Diethylamine is also colourless, volatile, inflammable, and caustic; boiling point, 134·6°. Triethylamine resembles ethylamine and diethylamine, and forms a beautiful orange-coloured crystalline salt with bichloride of platinum, containing ($(C_4H_5)_3N, HCl, PtCl_2$).

So much for the general method of procuring the greater part of the organic bases. Of course the iodide, and sometimes the bromide or chloride, of *any* alcohol radical may be employed, the amines formed containing that radical in the place of the ethyl in the example quoted. Moreover a primary amine may be acted upon by the iodide of a radical other than that it already contains, and the secondary amine thus formed acted upon by the iodide of a third radical different from either of the two existing in it, and finally the tertiary amine thus produced may be made to unite with the iodide of a fourth alcohol radical, and an ammonium called into existence having the four equivalents of hydrogen substituted by four different electro-positive radicals.

This method is important, not only in producing new organic bases, but as a means of ascertaining the constitution of an organic base after its composition has been determined by organic analysis. For obviously, if the base will only unite with one molecule of an alcohol radical, it must be a tertiary monamine; if with two, a secondary monamine; if with three, a primary monamine. The process does not, however, tell us in all cases whether the unknown radical already present in the body is monatomic, diatomic, or teratomic. The natural bases conine and codeine have in this way been shown to be secondary and tertiary monamines respectively, while nicotine, quinine, cinchonine, quinidine, brucine, and strychnine are either tertiary monamines or tertiary diamines.

The following organic bases, mostly formed by the above general method, have already been mentioned in this Cyclopædia, but for details concerning them, have been referred to the present article. Their general properties are similar to those of the ethyl derivatives fully described above; their special characteristics will only therefore be given.

Methylamine (N, H_2, C_2H_3) is frequently met with in organic decompositions; it is a gas, but may be condensed by a freezing mixture; it is inflammable, and at 55° Fahr. water dissolves 1150 times its bulk. *Dimethylamine* has not been isolated in a pure state. *Trimethylamine* ($N(C_2H_3)_3$) may often be recognised by its odour in the roe of herrings; it boils at 41° Fahr. and is inflammable. *Tetramethylammonium*, hyd. ox. ($N(C_2H_3)_4, O, HO$), crystallises in deliquescent needles; its salts also crystallise well. *Methyltriethylammonium*, hyd. ox. ($NC_2H_3, (C_4H_5)_3, O, HO$) is crystalline; its salts are very soluble in water. *Propylamine* ($NH_2C_6H_7$) has not been much studied. *Butylamine* ($NH_2C_8H_9$) is a colourless liquid, lighter than water; boiling point about 176° Fahr.; it forms stable crystalline salts. *Amylamine* ($NH_2, C_{10}H_{11}$) boils at 203° Fahr.; has a specific gravity of 0·7503, and is inflammable. *Diamylamine* ($NH(C_{10}H_{11})_2$) boils at 338° Fahr. *Triamylamine* ($N(C_{10}H_{11})_3$) boils at 494°·6 Fahr., and much resembles diamylamine. *Methyl-ethyl-amylamine* ($NC_2H_3C_4H_5C_{10}H_{11}$) is a colourless oil of agreeable aromatic odour; boiling point, 275° Fahr. *Diethylamylamine* ($N(C_4H_5)_2C_{10}H_{11}$) boils at 309°·2 Fahr., and with iodide of methyl gives the iodide of *methyl-diethyl-amyl-ammonium*. *Tetramylammonium*, hyd. ox. ($N(C_{10}H_{11})_4O\,HO$) occurs in deliquescent crystals. *Amyltriethylammonium*, hyd. ox. ($N(C_{10}H_{11})(C_4H_5)_3O\,HO$) forms crystalline salts, but is not crystalline itself. *Tricetylamine* ($N(C_{32}H_{33})_3$) crystallises in colourless needles; melting point, 102·2° Fahr. *Allylamine* ($NH_2C_6H_5$) distils between 356° and 374° Fahr.

A second method of forming organic bases is by the reduction of nitro-compounds. Many organic bodies suffer substitution of peroxide of nitrogen for hydrogen, when they are acted upon by nitric acid. The resulting nitro-compounds undergo a remarkable transformation when subjected to the influence of nascent hydrogen, sulphuretted hydrogen and other well-known reducing agents, NH_2 or H_2 taking the place of NO_4 or O_4. Thus benzole ($C_{12}H_6$) yields nitrobenzole ($C_{12}H_5NO_4$) on being acted upon by nitric acid; and nitrobenzol furnishes the organic base *phenylamine* ($NH_2C_{12}H_5$), or ANILINE, on being treated with sulphuretted hydrogen, thus:—

$$\underbrace{C_{12}H_5NO_4}_{\text{Nitrobenzol,}} + \underbrace{6HS}_{\text{Sulphuretted hydrogen.}} = \underbrace{NH_2C_{12}H_5}_{\text{Phenylamine.}} + \underbrace{4HO}_{\text{Water.}} + \underbrace{S_6}_{\text{Sulphur.}}$$

In a similar manner there have been formed *tolylamine* (toluidine) ($NH_2C_{14}H_7$); *xylylamine* (xylidine) ($NH_2C_{16}H_9$); *cumylamine* (cumidine) ($NH_2C_{18}H_{11}$); and *naphtylamine*, $NH_2(C_{20}H_7)$. Many derivatives of these compounds have been formed by applying the substitutive processes described under the first method: the following are the chief of them. *Methyl-phenylamine* ($NHC_2H_3C_{12}H_5$), a fragrant oil, boiling at 377·6° Fahr. *Ethyl-phenylamine* ($NHC_4H_5C_{12}H_5$), sp. gr. 0·954; boiling point 400° Fahr. *Methyl-ethyl-phenylamine* ($NC_2H_3C_4H_5C_{12}H_5$) resembles ethyl-phenylamine, but is not, like it, coloured blue by hypochlorite of lime. *Diethylphenylamine* ($N(C_4H_5)_2C_{12}H_5$), sp. gr. 0·939; boiling point 416° Fahr. *Ethyl-nitrophenylamine* contains ($NHC_4H_5[C_{12}H_4NO_4]$). *Amyl-phenylamine* ($NHC_{10}H_{11}C_{12}H_5$) is soluble in ether and boils at 496°·4 Fahr. *Methyl-amyl-phenylamine* ($NC_2H_3C_{10}H_{11}C_{12}H_5$) has an agreeable odour. *Ethyl-amyl-phenylamine* ($NC_4H_5C_{10}H_{11}C_{12}H_5$) boils at 503°·6 Fahr. *Diamyl-phenylamine* ($N(C_{10}H_{11})_2C_{12}H_5$) boils between 527° and 536° Fahr. *Cetyl-phenylamine* ($NHC_{32}H_{33}C_{12}H_5$) crystallises in plates, is not soluble in water, and melts at 107°·6 Fahr. *Dicetyl-phenylamine* ($N(C_{32}H_{33})_2C_{12}H_5$) is more fusible than cetylphenylamine. *Triethyl-phenyl-ammonium*, hyd. ox. ($N(C_4H_5)_3C_{12}H_5\,OHO$) forms crystalline salts. *Methyl-ethyl-amyl-phenyl-ammonium* hyd. ox. ($NC_2H_3C_4H_5C_{10}H_{11}C_{12}H_5\,OHO$) much resembles the preceding organic base. *Ethyl-tolylamine* ($NHC_4H_5, C_{14}H_7$) is a colourless oil, sp. gr. 0·939, boiling point 422°·6 Fahr. *Diethyl-tolylamine* ($N(C_4H_5)_2C_{14}H_7$) boils at 444° Fahr. *Triethyltolyl-ammonium*, hyd. ox. contains ($N(C_4H_5)_3C_{14}H_7\,OHO$).

The third general method of producing organic bases is by the decomposition of nitrogenous substances; the agents used being destructive distillation, boiling with caustic potash, and, in a few cases, oxidation; other agents, also, are used in a few special cases.

The destructive distillation of coal furnishes *pyridine* ($N(C_{10}H_5)'''$); *picoline* ($N(C_{12}H_7)'''$); *lutidine* ($N(C_{14}H_9)'''$); *collidine* ($N(C_{16}H_{11})'''$); *leucoline* ($N(C_{18}H_7)'''$); *lepidine* ($NC_{20}H_9)'''$); and *cryptidine* ($N(C_{22}H_{11})'''$). Methylamine, ethylamine, propylamine, butylamine, amylamine, pyridine, picoline, lutidine, and collidine are contained in Dippel's oil, a tarry matter obtained on destructively distilling bones. Beans also, on the application of heat furnish a base named *fabine*. Caustic potash converts the cyanates of methyl, ethyl, amyl, allyl, and phenyl into methylamine, ethylamine, amylamine, allylamine, and phenylamine respectively. The compound ureas, whose formulæ will presently be given, suffer a similar splitting up by heating with potash, ammonia being formed in addition to the bodies just mentioned. Soda-lime converts œnanthyl-aldehyd ($C_{14}H_{14}O_2$) into *tricaproylamine* ($N(C_{12}H_{13})_3$). Baryta converts creatin into *sarcosine* ($C_6H_7NO_4$). Brucine is converted by nitric acid into *cacotheline* ($C_{40}H_{22}(NO_4)_2N_2O_{10}$).

Finally, many of the organic bases already noticed, are formed during the putrefaction and fermentation of organic bodies.

The organic bases whose names and formulæ are here appended, are chiefly produced by the first general method. The cyanates of the alcohol radicals are the agents used for acting upon the ammonia, and no elimination of secondary product takes place. Moreover, they are mostly diamines and ammoniums, the organic bases hitherto described being all monamines.

Urea	$\left.\begin{matrix}(C_2O_2)''\\H_2\\H_2\end{matrix}\right\}N_2$	**Dimethyl-urea**	$\left.\begin{matrix}(C_2O_2)''\\(C_2H_3)_2\\H_2\end{matrix}\right\}N_2$
Ethyl-urea	$\left.\begin{matrix}(C_2O_2)''\\C_4H_5\ H\\H_2\end{matrix}\right\}N_2$	**Diethyl-urea**	$\left.\begin{matrix}(C_2O_2)''\\(C_4H_5)_2\\H_2\end{matrix}\right\}N_2$
Allyl-urea	$\left.\begin{matrix}(C_2O_2)''\\C_6H_5\ H\\H_2\end{matrix}\right\}N_2$	**Diallyl-urea (sinapoline)**	$\left.\begin{matrix}(C_2O_2)''\\(C_6H_5)_2\\H_2\end{matrix}\right\}N_2$
Sulphallyl-urea (thiosinamine)	$\left.\begin{matrix}(C_2S_2)''\\C_6H_5\ H\\H_2\end{matrix}\right\}N_2$	**Diphenyl-urea (flavine)**	$\left.\begin{matrix}(C_2O_2)''\\(C_{12}H_5)_3\\H_2\end{matrix}\right\}N_2$
Phenyl-urea	$\left.\begin{matrix}(C_2O_2)''\\C_{12}H_5\ H\\H_2\end{matrix}\right\}N_2$	**Ethyl-allyl-urea**	$\left.\begin{matrix}(C_2O_2)''\\C_4H_5, C_6H_5\\H_2\end{matrix}\right\}N_2$
Sulphophenyl-urea	$\left.\begin{matrix}(C_2S_2)''\\C_{12}H_5\ H\\H_2\end{matrix}\right\}N_2$	**Sulphethyl-allyl-urea**	$\left.\begin{matrix}(C_2S_2)''\\C_4H_5, C_6H_5\\H_2\end{matrix}\right\}N_2$
Sulphallyl-phenyl-urea	$\left.\begin{matrix}(C_2S_2)''\\C_6H_5, C_{12}H_5\\H_2\end{matrix}\right\}N_2$	**Ethyl-piperyl-urea**	$\left.\begin{matrix}(C_2O_2)''\\C_4H_5\ H\\(C_{10}H_{10})''\end{matrix}\right\}N_2$

Azophenylamine	$\left.\begin{matrix}(C_{12}H_4)''\\H_2\\H_2\end{matrix}\right\}N_2$
Nitrazophenylamine	$\left.\begin{matrix}C_{12}[H_3(NO)_4]''\\H_2\\H_2\end{matrix}\right\}N_2$
Azonaphthylamine	$\left.\begin{matrix}(C_{20}H_6)''\\H_2\\H_2\end{matrix}\right\}N_2$
Ethyl-picolyl-ammonium, hyd. ox.	$\left.\begin{matrix}C_4H_5(C_{12}H_7)'''N\\H\end{matrix}\right\}O_2$
Ethyl-leucolyl-ammonium, hyd. ox.	$\left.\begin{matrix}C_4H_5(C_{18}H_7)'''N\\H\end{matrix}\right\}O_2$
Methyl-morphyl-ammonium, hyd. ox.	$\left.\begin{matrix}C_2H_3(C_{34}H_{19}O_6)'''N\\H\end{matrix}\right\}O_2$
Ethyl-codyl-ammonium, hyd. ox.	$\left.\begin{matrix}C_4H_5(C_{36}H_{21}O_6)'''N\\H\end{matrix}\right\}O_2$
Ethyl-quinyl-ammonium, hyd. ox.	$\left.\begin{matrix}C_4H_5(C_{40}H_{24}NO_4)'''N\\H\end{matrix}\right\}O_2$

Ethyl-strychnyl-ammonium, hyd. ox. . $\left.\begin{matrix}C_4H_5(C_{42}H_{22}NO_4)'''N\\ H\end{matrix}\right\}O_2$

Ethyl-nicotyl-ammonium, hyd. ox. . $\left.\begin{matrix}C_4H_5(C_{10}H_7)'''N\\ H\end{matrix}\right\}O_2$

The radicals marked in the above formulæ as teratomic (''') are only empirically formulated, their true construction not being known. The formulæ of a few additional bodies have already been given as illustrations of diamines.

Organic phospherous, arsenic, and antimony bases.—It has been asserted that the great characteristic of organic bases is the presence of nitrogen. The statement must, however, be received with a certain amount of qualification, inasmuch as many true organic bases have been obtained containing no nitrogen. Their constitution and chemical deportment, nevertheless, show that these bases are strict analogues of the nitrogen bases—as those hitherto described are sometimes distinctively called—and that they are, in fact, amines and ammoniums in which nitrogen is replaced by phosphorus, or arsenic, or antimony. The remarks already made respecting the nomenclature of the derivatives of NH_3 and NH_4OHO apply equally to those of the compounds under consideration, the analogues of NH_3 being of course *phosphines, arsines*, or *stibines;* and those of NH_4, *phosphoniums, arsoniums*, or *stiboniums*. They are sometimes considered as derived from PH_3, AsH_3, and SbH_3 respectively; while the analogues of the hypothetical body NH_4 are as frequently spoken of as derivatives of the still more hypothetical bodies PH_4, AsH_4, and SbH_4.

The phosphorous, arsenic, and antimony bases are at present limited to the analogues of the tertiary monamines and ammoniums, no primary or secondary phosphines, arsines, or stibines having yet been produced, nor any analogues of diamines, triamines, or tetramines.

The best process for producing the phosphorous, arsenic, and antimony bases, consists in treating the metallic compounds of the alcohol radicals with the iodides, bromides, or chlorides of phosphorus, arsenic, and antimony, respectively; the triphosphines, triarsines, and tristibines thus produced readily combine with the bromides or iodides of the alcohol radicals, and form the iodides of phosphonium, arsonium, and stibonium, respectively. The latter bodies may be converted into hydrated oxides by the usual treatment with oxide of silver. Thus:—

$$\underbrace{3(C_4H_5Zn)}_{\text{Zincethyl.}} + \underbrace{PCl_3}_{\substack{\text{Terchloride of}\\ \text{phosphorus.}}} = \underbrace{3ZnCl}_{\substack{\text{Chloride of}\\ \text{zinc.}}} + \underbrace{(C_4H_5)_3P}_{\substack{\text{Triethyl-}\\ \text{phosphine.}}}$$

and

$$\underbrace{(C_4H_5)_3P}_{\text{Triethylphosphine.}} + \underbrace{C_4H_5I}_{\substack{\text{Iodide of}\\ \text{ethyl.}}} = \underbrace{P(C_4H_5)_4I}_{\substack{\text{Iodide of tetr-ethyl-}\\ \text{phosphonium.}}}$$

and

$$P(C_4H_5)_4I + \underbrace{AgO}_{\text{Oxide of silver.}} + HO = \underbrace{\left.\begin{matrix}(C_4H_5)_4P\\ H\end{matrix}\right\}O_2}_{\substack{\text{Hyd. ox. of tetr-ethyl-}\\ \text{phosphonium.}}}$$

The general terms of the phosphorous series are:—

Trimethylphosphine . . . . $\left.\begin{matrix}C_2H_3\\ C_2H_3\\ C_2H_3\end{matrix}\right\}P$

Triethylphosphine . . . . . $\left.\begin{matrix}C_4H_5\\ C_4H_5\\ C_4H_5\end{matrix}\right\}P$

Tetramethylphosphonium, hyd. ox. . $\left.\begin{matrix}(C_2H_3)_4P\\ H\end{matrix}\right\}O_2$

Trimethyl-ethylphosphonium, hyd. ox. . $\left.\begin{matrix}(C_2H_3)_3C_4H_5P\\ H\end{matrix}\right\}O_2$

Trimethyl-amylphosphonium, hyd. ox. . $\left.\begin{matrix}(C_2H_3)_3C_{10}H_{11}P\\ H\end{matrix}\right\}O_2$

Tetrethylphosphonium, hyd. ox. . . $\left.\begin{matrix}(C_4H_5)_4P\\ H\end{matrix}\right\}O_2$

Triethyl-vinylphosphonium, hyd. ox. . . $\left.\begin{matrix}(C_4H_5)_3C_4H_3P\\ H\end{matrix}\right\}O_2$

Phosphamines (R_6NSb), or diamines containing one equivalent of nitrogen replaced by phosphorus, have already been alluded to. There are a few *phosphammoniums*, $\left.\begin{matrix}R_6NP\\ H_2\end{matrix}\right\}O_4$, or diammoniums containing one equivalent of phosphorus in the place of one of nitrogen. The following are the formulæ of their hydrated oxides:—

Triethyl-ethylene-phosphammonium . $\left.\begin{matrix}(C_4H_5)_3(C_4H_4)''H_3NP\\ H_2\end{matrix}\right\}O_4$

Tetrethyl-ethylene-phosphammonium . $\left.\begin{matrix}(C_4H_5)_4(C_4H_4)''H_3NP\\ H_2\end{matrix}\right\}O_4$

Trimethyl-triethyl-ethylene-phosphammonium . . . . $\left.\begin{matrix}(C_2H_3)_3(C_4H_5)_3(C_4H_4)''NP\\ H_2\end{matrix}\right\}O_4$

Each of these three bodies combines with bichloride of platinum, and forms a salt containing two equivalents of the latter substance.

The number of arsenic and antimony bases is about the same as of organic phosphorous bases. As they contain decided metals, they are conveniently classed with ORGANO-METALLIC BODIES; in basic character, however, they yield to none of the organic bases.

ORGANIC CHEMISTRY. The science of chemistry is generally studied under two distinct heads or divisions, namely, first the chemistry of inorganic or mineral matters, and the numerous substances derived from them by artificial processes; and secondly, the chemistry of compounds obtained either directly or indirectly from organised beings, vegetable or animal. The first division constitutes *inorganic chemistry*, the second *organic chemistry*. So long as the peculiar compounds recognised as organic could be obtained only through the instrumentality of that combination of conditions sometimes termed *vital force*, the above division of the science was quite definite and philosophical, but as early as the year 1828, Wöhler succeeded in producing artificially the substance *urea*, a body which had up to that time been known only as a product of the animal organism. This discovery was followed many years later by the artificial formation of acetic acid, from exposing a mixture of protochloride of carbon, water, and chlorine to sunlight, and the reduction of the chloracetic acid thus obtained into acetic acid by an amalgam of potassium. The subsequent production of methyl from acetic acid added one of the organic radicals to the list of compounds obtainable from their elements without vital action. Although little further progress was made for several years in this department of chemical research, yet the artificial production of urea and acetic acid, together with their derivatives, completely broke down the barrier between so-called still *organic* and *inorganic* bodies; the name *organic* was retained for the class of bodies to which it had previously been assigned, although now obviously no longer strictly applicable.

Whilst the term *organic chemistry* is thus deprived of its original meaning, it would still be difficult to devise a more convenient name for that portion of the science which treats of compounds that are ordinarily though not invariably derived from organised beings, hence the continuance of its use to the present day.

Classification of organic compounds.—The number of compounds included within the domain of organic chemistry has of late years become so vast, owing to the laborious researches of numerous chemists, as to render some system of classification almost absolutely necessary to enable the mind to grasp a branch of knowledge embracing such an infinite number of experimentally demonstrated facts.

Whilst on the one hand, it cannot be said that organic chemistry is not yet sufficiently developed to admit of satisfactory generalisations, on the other, it is evident that in a science which is yearly making such rapid progress, any system of classification, however satisfactory when first proposed, can scarcely be expected long to fulfil all the conditions demanded of it. Hence it would not be difficult to advance objections against the excellent system recently submitted by M. Gerhardt—a system which, notwithstanding all drawbacks, is generally admitted to be by far the best hitherto proposed. It has therefore been adopted as far as possible in the chemical articles of this Cyclopædia.

The essential portion of Gerhardt's system may be explained in very few words.

All organic compounds which have been sufficiently studied are arranged around a certain number of centres or pivots chosen from amongst the two homologous series of acids, beginning respectively with formic acid and benzoic acid. The two great divisions thus created are termed *sections*, and the families arranged about the centres are named *series*. Thus we get the following arrangement:—

FIRST SECTION.

Formic series.
Acetic series.
Propionic series.
Butyric series.
Valeric series.
Caproic series.
Œnanthylic series.
Caprylic series.
Pelargonic series.
Capric or Rutic series.
Lauric series.
Myristic series.
Palmitic series.
Stearic series.
Cerotic series.
Melissic series.

SECOND SECTION.

Benzoic series.
Toluic series.
Xylic series.
Cuminic series.
Cymenic series.

Each series is subdivided into *groups:* the benzoic series for instance consists of eight groups. [BENZOIC SERIES.] Under each group will generally be found described or mentioned every individual member belonging to that group, thus under BENZOIC GROUP, one of the groups of the Benzoic series, a large number of compounds more or less intimately connected with each other, and with benzoic acid, will be found described.

Constitution of organic compounds.—One of the most difficult, but at the same time most interesting and important problems which present themselves to the chemist, is the internal arrangement or constitution of organic compounds. A child may so far investigate a watch for instance, as to discover that it consists of silver, steel, and glass, nay he might even without difficulty make his research a quantitative one, and ascertain the weights of these different materials, which enter into the composition of the instrument, but such an investigation would obviously leave the most interesting part of the history of the watch untouched; it would tell him nothing either of the arrangement of these materials or of the respective functions of the wheels, the springs, the hands, &c., the investigation of which would obviously involve a much more laborious and especially a much more intellectual inquiry. So in chemistry, the mere determination of the composition of a compound stops short of the more interesting attributes of the body—its internal arrangement and the functions performed by its several constituents. Hence the higher problem, difficult as its solution undoubtedly is, has never been lost sight of by the chemical investigator. With a view to its solution he on the one hand submits organic compounds to various processes, in order to take them to pieces; and on the other, he brings together what he conceives to be their proximate constituents, in order if possible to build up the substance he is investigating; and thus he endeavours from both the points of view thus afforded to arrive at some conclusion as to their internal constitution.

It is quite unnecessary here to notice the various views of a more general character which, with a greater or less amount of this kind of labour, have been arrived at by different chemists; it will be here sufficient to mention one such general view, which has for some years found very extensive acceptance amongst chemists. This view, which might be called the doctrine of types, regards all organic bodies as constituted in conformity with certain inorganic types,—as being cast, so to speak, in the moulds of these inorganic compounds. The four principal types are

Hydrogen Type.	Hydrochloric acid Type.	Water Type.	Ammonia Type.
$\left.\begin{matrix}H\\H\end{matrix}\right\}$	$\left.\begin{matrix}H\\Cl\end{matrix}\right\}$	$\left.\begin{matrix}H\\H\end{matrix}\right\}O_2$	$N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.$

The radicals, both positive and negative, belong to the hydrogen type. The haloid compounds of these radicals are formed upon the hydrochloric acid type. The alcohols, ethers, acids, and ethereal salts belong to the water type; whilst the ammonia type includes the organic bases and the amides. In this Cyclopædia the formulæ of organic bodies are generally written in accordance with these types.

In the concluding remarks of the article Organometallic Bodies, an endeavour is made to show that these bodies throw considerable light upon the nature of the so-called organic radicals, and hence also upon the constitution of organic compounds in general. If the views there expressed as to the nature of organometallic bodies and their compounds be correct, the extension of those views to the organic compounds of carbon becomes inevitable. Regarded from this point of view the double atom of carbon, like that of tin, is quadratomic in perchloride of carbon and carbonic acid

$$C_2\left\{\begin{matrix}Cl\\Cl\\Cl\\Cl\end{matrix}\right. \qquad C_2\left\{\begin{matrix}O\\O\\O\\O\end{matrix}\right.$$

and biatomic in protochloride of carbon and carbonic oxide:

$$C_2\left\{\begin{matrix}Cl\\Cl\end{matrix}\right. \qquad C_2\left\{\begin{matrix}O\\O\end{matrix}\right.$$

In other words, the quadratomic stage in carbon compounds is the stage of maximum saturation, whilst the biatomic stage is one of exalted stability. If we substitute an atom of chlorine in perchloride of carbon by one of ethyl, we produce a body having the formula of trichlorhydrin:

$$C_2\left\{\begin{matrix}C_4H_5\\Cl\\Cl\\Cl\end{matrix}\right.$$

If now a second atom of chlorine be substituted by one of hydrogen, we have a body exhibiting the composition of bichloride of propylene:

$$C_2\left\{\begin{matrix}C_4H_5\\H\\Cl\\Cl\end{matrix}\right.$$

The treatment of this body with alcoholic potash removes hydrochloric acid, and reduces it to the protochloride type

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\Cl\\Cl\end{matrix}\right.}_{\text{Bichloride of propylene.}} + KO = \underbrace{C_2\left\{\begin{matrix}C_4H_5\\Cl\end{matrix}\right.}_{\text{Chloride of Allyl.}} + KCl + HO.$$

The substitution of a third atom of hydrogen for chlorine, gives the formula of chloride of propyl:

$$C_2\left\{\begin{matrix}C_4H_5\\H\\H\\Cl\end{matrix}\right.$$

whilst the substitution of the last atom of chlorine by hydrogen yields hydride of propyl, or by ethyl, the so-called double radical ethyl propyl:

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\H\\H\end{matrix}\right.}_{\text{Hydride of propyl.}} \qquad \underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\H\\C_4H_5\end{matrix}\right.}_{\text{Ethyl-propyl.}}$$

In like manner, if we substitute an atom of oxygen in carbonic acid by ethyl, we have propionic anhydride

$$\underbrace{C_2\left\{\begin{matrix}O\\O\\O\\O\end{matrix}\right.}_{\text{Carbonic acid.}} \qquad \underbrace{C_2\left\{\begin{matrix}(C_4H_5)\\O\\O\\O\end{matrix}\right.}_{\text{Propionic anhydride.}}$$

A second atom substituted by hydrogen yields propionic aldehyde:

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\O\\O\end{matrix}\right.}_{\text{Propionic aldehyde.}}$$

The replacement of a third atom of oxygen by hydrogen produces propylic ether:

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\H\\O\end{matrix}\right.}_{\text{Propylic ether.}}$$

Whilst the replacement of the last atom of oxygen by hydrogen, produces hydride of propyl, and by uniatomic peroxide of hydrogen, propylic alcohol:

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\H\\H\end{matrix}\right.}_{\text{Hydride of propyl.}} \qquad \underbrace{C_2\left\{\begin{matrix}C_4H_5\\H\\H\\HO_2\end{matrix}\right.}_{\text{Propylic alcohol.}}$$

The glycols are also constructed upon the carbonic acid type:

$$\underbrace{C_2\left\{\begin{matrix}O\\O\\O\\O\end{matrix}\right.}_{\text{Carbonic acid.}} \qquad \underbrace{C_2\left\{\begin{matrix}C_2H_3\\H\\HO_2\\HO_2\end{matrix}\right.}_{\text{Glycol.}}$$

And to the same type belongs also the teracid alcohol glycerin

$$C_2\left\{\begin{matrix}C_4H_5\\HO_2\\HO_2\\HO_2\end{matrix}\right.$$

Under the influence of iodide of phosphorus, glycerin yields iodide of allyl:

$$\underbrace{C_2\left\{\begin{matrix}C_4H_5\\HO_2\\HO_2\\HO_2\end{matrix}\right.}_{\text{Glycerin.}} \qquad \underbrace{C_2\left\{\begin{matrix}C_4H_5\\I\end{matrix}\right.}_{\text{Iodide of allyl.}}$$

Here we have a reduction from the carbonic acid to the carbonic oxide type, of precisely the same nature as that which occurs when cacodylic acid is reduced to oxide of cacodyl. Allylic compounds are therefore constructed upon the carbonic oxide type:

$$\underbrace{C_2\left\{\begin{matrix}O\\O\end{matrix}\right.}_{\text{Carbonic oxide.}}, \quad \underbrace{C_2\left\{\begin{matrix}C_4H_5\\I\end{matrix}\right.}_{\text{Iodide of allyl.}}, \quad \underbrace{C_2\left\{\begin{matrix}C_4H_5\\HO_2\end{matrix}\right.}_{\text{Allylic alcohol.}}$$

It would be easy greatly to extend this view of the constitution of organic carbon compounds, but the above examples are sufficient to indicate its general application. It is from carbonic acid, water and ammonia that nature constructs her most complex organic compounds; these inorganic substances are the essential food of plants, which thus find ready formed in the air and earth the moulds in which to cast their most complicated chemical compounds, just as animals find ready formed in their vegetable food, the plastic constituents which they employ for the construction of the various parts of their organisms.

ORGANIC COMPOUNDS, *Artificial Production of.* Under Organic Chemistry allusion is made to the production of urea, acetic acid, and methyl (three essentially organic compounds), by purely artificial methods, and without any assistance, direct or indirect, from vital action. The recent ingenious researches of M. Berthelot have greatly extended this branch of chemical inquiry, and have in a most important degree increased the number of bodies capable of artificial formation. The production of chloride of methyl, and the members of the olefiant gas family up to amylene ($C_{10}H_{10}$), furnishes us with the whole series of alcohols and their derivatives, from amylic alcohol downwards. Phenylic alcohol and naphthaline, both artificially produced by Berthelot, yield a host of interesting bodies; whilst phenylcarbonic acid enables us to step from the phenylic to the salicylic group, since, when treated with hyponitrous acid, it yields salicylic acid. Lastly, M. Berthelot has succeeded in artificially forming glycerin, the basis of animal and vegetable oils and fats. Grape sugar has also been added to the list; but, being produced by the contact of glycerin with putrifying animal matter, it cannot be said to be formed altogether without the agency of vitality, although the putrifying organic matter contributes none of its constituents to the new compound, and does not undergo any appreciable change in weight or appearance during the process. These substances yield such a numerous class of derivatives, that upwards of 700 distinct organic compounds can now be produced from their elements without the agency of vitality.

Amongst the most important organic compounds thus formed, the following may be mentioned :—

Name.	Formula.
Oxalic acid	$(C_2O_3, HO)_2$
Hydrocyanic acid	C_2N, H
Light carburetted hydrogen	C_2H_4
Urea	$C_2N_2H_4O_2$
Formic acid (acid of ants)	C_2HO_3, HO
Chloroform	C_2HCl_3
Acetic acid	$C_4H_3O_3, HO$
Alcohol	C_4H_5O, HO
Ether	$(C_4H_5O)_2$
Olefiant gas	C_4H_4
Acetic ether	$C_4H_5O, C_4H_3O_3$
Oil of garlic	$(C_6H_5S)_2$
Oil of mustard	C_6H_5S, C_2NS
Glycerin	$C_6H_8O_6$
Butyric acid	$C_8H_7O_3, HO$
Pine-apple flavour (butyric ether)	$C_8H_7O_3, C_4H_5O$
Succinic acid	$C_8H_4O_6, 2HO$
Valerianic acid	$C_{10}H_9O_3, HO$
Pear flavour (acetate of amyl)	$C_4H_3O_3, C_{10}H_{11}O$
Apple flavour (valerianate of amyl)	$C_{10}H_9O_3, C_{10}H_{11}O$
Lactic acid	$C_{12}H_{12}O_{12}$
Grape sugar ?	$C_{12}H_{12}O_{12}$
Caproic acid	$C_{12}H_{11}O_3, HO$
Benzole	$C_{12}H_6$
Nitrobenzole	$C_{12}H_5NO_4$
Aniline	$N(C_{12}H_5)H_2$
Phenyl alcohol (creasote)	$C_{12}H_5O, HO$
Picric acid	$C_{12}H_2(NO_4)_3O, HO$
Salicylic acid	$C_{14}H_5O_5, HO$
Salicylate of methyl (oil of wintergreen)	$C_{14}H_5O_5, C_2H_3O$
Naphthalin	$C_{20}H_8$

The artificial formation of urea, lactic acid, and caproic acid, is interesting in connection with certain functions of the animal economy. Pine-apple oil and apple oil are instances of the artificial production of the delicate flavours of fruit, whilst oil of wintergreen and nitrobenzole are like examples of the formation of esteemed perfumes. But of all the bodies hitherto thus produced, alcohol, glycerin, and sugar are undoubtedly the most deeply interesting, owing to the part they take in the nutrition of animals: they prove to us the possibility of producing, without vegetation or any vital intervention, an important part of the food of man. Should the chemist also succeed in forming artificially the nitrogenous constituents of food, without which life cannot be maintained, it would then be possible for a man planted upon a barren rock, and furnished with the necessary apparatus and inorganic materials, to support life without either animal or vegetable food. No one of these nitrogenous constituents has, however, yet been artificially produced, and the absence of all clue to their rational constitution forms at present a formidable barrier to their non-vital production.

Considerations here naturally suggest themselves regarding the possibility of economically replacing natural processes by artificial ones in the formation of organic compounds. At present the possibility of doing this only attains to probability in the case of rare and exceptional products of animal and vegetable life. Thus, valerianic acid, which for a long time was extracted from the root of the *Valeriana officinalis*, could now probably be more cheaply prepared from its elements; but a still cheaper source of this acid has been in the meantime discovered, namely, the oxidation of amylic alcohol, a waste product formed in the manufacture of spirit of wine, and obtainable at such a moderate cost as to prevent, in an economical point of view, the successful production either of amylic alcohol or valerianic acid by any artificial and exclusively non-vital processes at present known. It is also highly probable that if we could produce artificially such bodies as quinine and the rare alkaloids, or alizarin, and similar powerful and valuable organic colouring matters, we should be able to compete with organic life in the formation of these bodies; nevertheless, the discovery of the processes of artificial formation would doubtless be preceded by a knowledge of methods by which such rare bodies could be produced from more abundant and consequently cheaper forms of vegetable or animal matter; and it is therefore exceedingly improbable that any purely non-vital process will be successfully and at the same time economically employed for the manufacture even of such rare and valuable vital products. Such being the economical bearings of the case with regard to the rare and exceptional educts of vitality, when we turn to consider the great staple products of the animal and vegetable kingdoms the hope of rivalling natural processes becomes faint indeed. By no process at present known could we produce sugar, glycerin, or alcohol from their elements at one hundred times their present cost as obtained through the agency of vitality. But, although our present prospects of rivalling vital processes in the economical production of staple organic compounds such as those constituting the food of man are so exceedingly slight, yet it would be rash to pronounce their ultimate realisation impossible. It must be remembered that this branch of chemistry is as yet in its merest infancy, and that it has hitherto attracted the attention of few minds; and further, that many analogous substitutions of artificial for natural processes have been achieved. Thus, under certain circumstances, we find it less economical to propel our ships by the force of the wind, and our carriages by animal power, than to employ steam power for these purposes. We do not find it desirable to wait for the bleaching of our calicoes by the sun's rays; and even the grinding of corn is no longer entirely confided to wind and water power.

In such cases, where contemporaneous natural agencies have been superseded, we have almost invariably drawn upon that grand store of force collected by the plants of bygone ages, and conserved in our coalfields. It is the solar heat of a past epoch that evolves mechanical power from our steam-engines, enabling us to accomplish that which the present forces of nature alone are not capable of performing. One important element in cheap production is *time*, and it is precisely in regard to this element that we economically supersede in the above instances the contemporary resources of nature. Now time is also an important element in the natural production of food, and although it is true that the amount of labour required for the growth of a given weight of food is not considerable, yet it is nevertheless true that this weight requires a whole year for its production. By the vital process of producing food we can only have one harvest in each year. But if we were able to manufacture that food from its elements without vital agency, there would be nothing to prevent us from obtaining a harvest every week; and thus we might, in the production of food, supersede the present vital agencies of nature, as we have already done in other cases, by laying under contribution the accumulated forces of past ages, which would thus enable us to obtain in a small manufactory, and in a few days, effects which can only be otherwise realised from present natural agencies when exerted upon vast areas of land, and through considerable periods of time.

ORGANIC COMPOUNDS, CLASSIFICATION OF. [Organic Chemistry.]

ORGANIC COMPOUNDS, CONSTITUTION OF. [Organic Chemistry.]

ORGANIC RADICALS. The large number of simple atoms which generally go to form an organic substance are not bound together into one homogeneous compound, but are to a great extent arranged in groups, each group playing the part of a simple or elementary body. Such groups performing this function are termed *organic* or *compound radicals*. Thus, alcohol contains 4 equivalents of carbon, 6 of hydrogen, and 2 of oxygen, but these elements are supposed to be arranged in the alcohol in the following manner :—

$$\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2$$

That is, 4 equivalents of carbon and 5 of hydrogen exist in the alcohol in the form of a compound as distinct and independent as the remaining equivalent of hydrogen; this compound of carbon and hydrogen, which is called *ethyl*, is an example of an organic radical, or of an organic group playing the part of an elementary body: for by certain chemical operations, the radical ethyl can be removed from alcohol and its place supplied by hydrogen, a kind of substitution which transforms the alcohol into water. Thus alcohol and water are related to each other, as shown in the following formulæ :—

$$\underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}} \qquad \underbrace{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2}_{\text{Water.}}$$

The simple or elementary radicals comprise, on the one hand, bodies which, like potassium, zinc, iron, and hydrogen, are electro-positive or basylous in their character; and, on the other, substances such as oxygen, sulphur, and chlorine, which are electro-negative or chlorous in their behaviour. The organic radicals admit of a precisely similar classification: some of them, such as methyl, ethyl, phenyl, &c., imitating hydrogen, zinc, or iron in their functions; whilst formyl, othyl, cyanogen, &c., resemble chlorine and sulphur in their chemical relations. Further, just as we have uniatomic, biatomic, and teratomic metals (that is, metals capable of combining with one, two, or three equivalents of other elements), so we have organic radicals which comport themselves in exactly the same manner in their modes of combination. Thus ethyl (C_4H_5) is a uniatomic, ethylene (C_4H_4'') a biatomic, and the radical of glycerin (C_6H_5''') a teratomic radical. When a radical has such a polyatomic character, its degree is represented by dashes placed after the formula, as in the cases just mentioned.

There are several families of homologous organic radicals, and they are usually distinguished by certain general formulæ. One of the most important of these families has the general formula $CnHn + 1$, in which n represents an even number, such as 2, 4, 6, &c. The following are a few of the chief radicals belonging to this family:—

Methyl	C_2H_3	or	$\left.\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right\}$
Ethyl	C_4H_5	or	$\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}$
Propyl	C_6H_7	or	$\left.\begin{matrix}C_6H_7\\C_6H_7\end{matrix}\right\}$
Butyl	C_8H_9	or	$\left.\begin{matrix}C_8H_9\\C_8H_9\end{matrix}\right\}$
Amyl	$C_{10}H_{11}$	or	$\left.\begin{matrix}C_{10}H_{11}\\C_{10}H_{11}\end{matrix}\right\}$

A second family has the general formula $CnHn - 7$. None of its members are yet known in a separate state, but analogy admits of no doubt as to their existence in certain well-known organic compounds. The following are some of the most important members of this family:—

Phenyl	$C_{12}H_5$	or	$\left.\begin{matrix}C_{12}H_5\\C_{12}H_5\end{matrix}\right\}$
Toluenyl	$C_{14}H_7$	or	$\left.\begin{matrix}C_{14}H_7\\C_{14}H_7\end{matrix}\right\}$
Cumenyl	$C_{18}H_{11}$	or	$\left.\begin{matrix}C_{18}H_{11}\\C_{18}H_{11}\end{matrix}\right\}$
Cymenyl	$C_{20}H_{13}$	or	$\left.\begin{matrix}C_{20}H_{13}\\C_{20}H_{13}\end{matrix}\right\}$

A third family has the general formula $CnHn - 1$. It has hitherto been very little explored, and the only member known with certainty is—

Allyl	C_6H_5	or	$\left.\begin{matrix}C_6H_5\\C_6H_5\end{matrix}\right\}$

All the families above described contain only uniatomic radicals, but by the abstraction of one equivalent of hydrogen they all yield corresponding biatomic radicals. Thus:—

$$\underbrace{C_4H_5}_{\text{Ethyl.}} - H = \underbrace{C_4H_4''}_{\text{Ethylene.}}$$

The following are the chief biatomic radicals of the form $CnHn$:—

Methylene	C_2H_2''
Ethylene	C_4H_4''
Propylene	C_6H_6''
Butylene	C_8H_8''
Amylene	$C_{10}H_{10}''$

With the exception of methylene, all these biatomic radicals can be readily obtained in a separate state.

A family of teratomic radicals of the form $CnHn - 1$ appears also to exist, although up to the present time only one member is known, and that only in combination. Glycerin contains this radical, which is termed—

Glyceryl	C_6H_5'''

All the radicals hitherto considered are *positive* or *basylous* radicals, but by the exchange of two equivalents of hydrogen for two of oxygen they are all transformed into *negative* or *chlorous* radicals; thus, the positive radical ethyl, minus two atoms of hydrogen, plus two of oxygen, passes into the negative radical othyl or acetyl:—

$$\underbrace{C_4H_5}_{\text{Ethyl.}} + O_2 - H_2 = \underbrace{C_4H_3O_2}_{\text{Othyl.}}$$

Hitherto uniatomic negative radicals alone have been clearly established, but there can be no doubt that biatomic and teratomic positive radicals, by a similar substitution of oxygen for hydrogen, pass into corresponding negative radicals of the same polyatomic character.

The following are some of the most important uniatomic negative radicals:—

1. Of the form $CnHn - 1O_2$. Derivatives from $CnHn + 1$.

Formyl	C_2HO_2	or	$\left.\begin{matrix}C_2HO_2\\C_2HO_2\end{matrix}\right\}$
Othyl or acetyl	$C_4H_3O_2$	or	$\left.\begin{matrix}C_4H_3O_2\\C_4H_3O_2\end{matrix}\right\}$
Propionyl	$C_6H_5O_2$	or	$\left.\begin{matrix}C_6H_5O_2\\C_6H_5O_2\end{matrix}\right\}$
Butyryl	$C_8H_7O_2$	or	$\left.\begin{matrix}C_8H_7O_2\\C_8H_7O_2\end{matrix}\right\}$

2. Of the form $CnHn - 9O_2$. Derivatives from $CnHn - 7$.

Benzöyl	$C_{14}H_5O_2$	or	$\left.\begin{matrix}C_{14}H_5O_2\\C_{14}H_5O_2\end{matrix}\right\}$
Toluyl	$C_{16}H_7O_2$	or	$\left.\begin{matrix}C_{16}H_7O_2\\C_{16}H_7O_2\end{matrix}\right\}$
Cumyl	$C_{20}H_{11}O_2$	or	$\left.\begin{matrix}C_{20}H_{11}O_2\\C_{20}H_{11}O_2\end{matrix}\right\}$

3. Of the form $CnHn - 3O_2$. Derivatives from $CnHn - 1$.

Acryl	$C_6H_3O_2$	or	$\left.\begin{matrix}C_6H_3O_2\\C_6H_3O_2\end{matrix}\right\}$

In addition to the bodies above described, another class, termed *double radicals*, are known to chemists. These are formed by the union of any two single positive radicals, or of a positive with a negative radical. No double negative radical has yet been obtained. The following instances will suffice to indicate the composition of the double radicals:—

Ethyl-amyl	$\left.\begin{matrix}C_4H_5\\C_{10}H_{11}\end{matrix}\right\}$
Acetone or methyl-othyl	$\left.\begin{matrix}C_4H_3O_2\\C_2H_3\end{matrix}\right\}$

The double radicals containing both a positive and a negative constituent are better known under the name of ketones. [KETONES.]

It has been stated above that of the single radicals, those belonging to the positive division only have been isolated, and of these the members of the family $CnHn - 7$ are entirely unknown in a separate state. The two methods admitting of general application for the isolation of the positive radicals, are the following:—

1. The action of zinc, potassium, or sodium, upon the iodides of the radicals. Thus, for the isolation of ethyl:—

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of Ethyl.}} + Zn_2 = 2ZnI + \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}}_{\text{Ethyl.}}$$

2. By the action of nascent oxygen, evolved from the positive pole of a voltaic battery, upon the fatty acids. Thus, for the isolation of methyl:—

$$\underbrace{2\left.\begin{matrix}C_4H_3O_2\\H\end{matrix}\right\}O_2}_{\text{Acetic acid.}} + O_2 = \underbrace{2C_2O_4}_{\text{Carbonic acid.}} + 2HO + \underbrace{\left.\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right\}}_{\text{Methyl.}}$$

ORGANOMETALLIC BODIES. A numerous family of chemical compounds in which compound organic radicals, such as methyl, ethyl, &c., are united with metals, in a manner analogous to that in which the elementary radical chlorine is combined with sodium and zinc, in sea-salt and chloride of zinc. If, for instance, in chloride of zinc we replace the chlorine by ethyl, we produce one of the bodies belonging to this family, namely, zincethyl:—

$$\underbrace{ZnCl}_{\text{Chloride of zinc.}} \qquad \underbrace{Zn(C_4H_5)}_{\text{Zincethyl.}}$$

Although organometallic bodies as a distinct class of organic compounds are, with one exception, the creation of the last ten years, yet the derivatives of these bodies have been known for a much longer period. From the time that an organic acid was first united with a metallic base these organic compounds containing metals date their existence. It is true that such compounds containing a metallic constituent have not been regarded from this point of view, but a little consideration will serve to show that they stand in the same relation to organometallic bodies, in the strict sense of the term, as the alcohol radicals occupy with regard to the ethers, alcohols, acids, and numerous other families derived from these radicals.

Thus, zincethyl yields by oxidation ethylate of zinc—

$$\underbrace{ZnC_4H_5}_{\text{Zincethyl.}} + O_2 = \underbrace{ZnO, C_4H_5O}_{\text{Ethylate of zinc,}}$$

a body which, although unknown until formed by this re-action, has undoubted and well-known analogies in the ethylates of potash and soda.

By suitable processes of oxidation, ethylate of zinc may be converted into acetate of zinc:—

$$ZnO, C_4H_5O + 4O = \left.\begin{matrix}C_4H_3O_2\\Zn\end{matrix}\right\}O_2 + \left.\begin{matrix}H\\H\end{matrix}\right\}O_2$$

Again, potassium-methyl and sodium-methyl under the influence of carbonic acid yield the acetates of potash and soda:—

$$\underbrace{NaC_2H_3}_{\text{Sodium methyl.}} + \underbrace{C_2O_4}_{\text{Carbonic acid.}} = \underbrace{\left.\begin{matrix}C_4H_3O_2\\Na\end{matrix}\right\}O_2}_{\text{Acetate of soda.}}$$

Such being the relations between organometallic bodies in the usual acceptation of the term, and that far more numerous class of derivatives to which the same name might without impropriety be applied, it is scarcely necessary to remark that this article will be confined to the consideration of organometallic bodies in the usual and more restricted sense of the term.

FORMATION OF ORGANOMETALLIC BODIES.

Organometallic bodies admit of being formed by a great variety of processes, which, however, with very few exceptions, admit of being grouped under four heads.

1. *Formation by the union of an organic radical in statu nascenti with the metal.*—Organic compounds containing zinc, cadmium, magnesium, aluminium, glucinum, tin, and mercury, are produced by this method.

Zincethyl, which may be regarded as the type of organo-zinc compounds, is obtained by digesting a mixture of equal volumes of iodide of ethyl and ether with granulated zinc in a strong glass or copper vessel, at a temperature of about 260° Fahr., for several hours. Subsequent distillation gives a mixture of zinc-ethyl and ether, from which the former is obtained pure by rectification. The re-action may be thus expressed—

$$\underbrace{2C_4H_5I}_{\text{Iodide of ethyl.}} + Zn_4 = \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}Zn_2}_{\text{Zincethyl.}} + 2\left.\begin{matrix}Zn\\I\end{matrix}\right\}$$

Zincmethyl and ***zincamyl*** are produced by analogous processes.

The same method of formation yields cadmium-ethyl, when iodide of ethyl is digested with cadmium at a temperature of from 212° to 280°.

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Cd_4 = 2CdI + \underbrace{2(C_4H_5Cd)}_{\text{Cadmium-ethyl.}}$$

Treated with iodide of ethyl, magnesium gives ***magnesium-ethyl***, the reaction commencing briskly at ordinary temperatures, but requiring a heat of 248° to 266° for its completion.

$$4Mg + 2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\} = Mg_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. + 2\left.\begin{matrix}Mg\\I\end{matrix}\right\}$$

The homologous re-action with iodide of methyl appears also to yield ***magnesium-methyl.***

$$4Mg + 2\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\} = Mg_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right. + 2\left.\begin{matrix}Mg\\I\end{matrix}\right\}$$

Similarly treated, aluminium yields, at temperatures from 212° Fahr. to 266° F., ***Aluminium-ethyl*** and ***Aluminium-methyl.***

$$3\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\} + Al_4 = \left(Al_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right. + Al_2\left\{\begin{matrix}I\\I\\I\end{matrix}\right.\right)$$

$$3\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\} + Al_4 = \left(Al_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\end{matrix}\right. + Al_2\left\{\begin{matrix}I\\I\\I\end{matrix}\right.\right)$$

Double compounds of aluminium-ethyl and aluminium-methyl, with the iodide of aluminium, are here formed, and the former bodies have not yet been obtained with certainty free from iodide of aluminium.

Glucinium-ethyl appears also to be formed under similar circumstances, although its existence has not yet been confirmed by analysis.

Compounds of tin with alcohol radicals.—Although these organometallic bodies can be obtained by other processes, the general method we are now considering is doubtless the most convenient mode of producing the most important of them, as well as their iodine compounds.

Tin is capable of forming three distinct classes of binary inorganic compounds, which may be represented by the following general formulæ :—

$$Sn_2\left\{\begin{matrix}R\\R\end{matrix}\right. \qquad Sn_2\left\{\begin{matrix}R\\R\\R\end{matrix}\right. \qquad Sn_2\left\{\begin{matrix}R\\R\\R\\R\end{matrix}\right.$$

In these and the following formulæ R represents any radical positive or negative, R + a positive organic radical, and R — a negative inorganic radical.

This threefold atomic character of the metal tin renders the results of its action upon the iodides of the alcohol radicals considerably less simple than those which we have hitherto considered. Without taking into account compounds to which a still more complex constitution has been assigned, the existence of the following series of organometallic bodies containing tin has been established :—

$$(1)\quad Sn_2\left\{\begin{matrix}R+\\R+\end{matrix}\right. \qquad\qquad (4)\quad Sn_2\left\{\begin{matrix}R+\\R+\\R+\\R+\end{matrix}\right.$$

$$(2)\quad Sn_2\left\{\begin{matrix}R+\\R+\\R+\end{matrix}\right. \qquad\qquad (5)\quad Sn_2\left\{\begin{matrix}R+\\R+\\R+\\R-\end{matrix}\right.$$

$$(3)\quad Sn_2\left\{\begin{matrix}R+\\R+\\R-\end{matrix}\right. \qquad\qquad (6)\quad Sn_2\left\{\begin{matrix}R+\\R+\\R-\\R-\end{matrix}\right.$$

The second and fourth of these series have not yet been produced by the method we are now considering.

FIRST SERIES.

Stannous ethide, or *Stanethyl* ($Sn_2(C_4H_5)_2$), is formed in small quantity by the action of heat upon a mixture of iodide of ethyl and tin—

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Sn_4 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Stannous ethide.}} + 2SnI$$

Stannous methide, or ***Stanmethyl*** ($Sn_2(C_2H_3)_2$), is doubtless formed under similar conditions.

THIRD SERIES.

The third series of stann-organic compounds are formed by the following re actions :—

$$\underbrace{2\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\}}_{\text{Iodide of methyl.}} + Sn_2 = \underbrace{Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\I\end{matrix}\right.}_{\text{Dimethiodide of tin.}} + SnI$$

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Sn_2 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Diethiodide of tin.}} + SnI$$

FIFTH SERIES.

The following chemical changes express the mode of formation of compounds belonging to this series :—

$$\underbrace{3\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\}}_{\text{Iodide of methyl.}} + Sn_4 = \underbrace{Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\\I\end{matrix}\right.}_{\text{Trimethiodide of tin.}} + 2SnI$$

$$\underbrace{3\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Sn_4 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Triethiodide of tin.}} + 2SnI$$

SIXTH SERIES.

The most abundant products of the action of tin upon the iodides of the alcohol radicals belong to this series. Indeed, if the action be produced by light instead of heat, this series of bodies is formed almost to the complete exclusion of the others. It is necessary, however, to remark, that the materials exposed to light should be completely excluded from atmospheric oxygen, otherwise the liquid assumes an orange colour, and the action is so effectually arrested that an exposure for several months to sunlight, concentrated by a parabolic mirror, will scarcely produce any appreciable change. The following re-actions explain the formation of bodies belonging to this series :—

$$\underbrace{2\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\}}_{\text{Iodide of methyl.}} + Sn_2 = \underbrace{Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\I\\I\end{matrix}\right.}_{\text{Stannic dimethiodide.}}$$

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Sn_2 = \underbrace{Sn\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.}_{\text{Stannic diethiodide of tin.}}$$

Mercury compounds.—The re-action of mercury upon the iodides of the alcohol radicals gives rise to two classes of organic compounds, the general formulæ of which may be thus written :—

$$1.\quad Hg\left\{\begin{matrix}R+\\R-\end{matrix}\right.$$

$$2.\quad Hg\left\{\begin{matrix}R+\\R+\end{matrix}\right.$$

The first series only of these bodies can be produced by the general mode of formation now being considered, but the members of the second series are readily obtained by the action of an organo-zinc compound upon those of the first. For the production of the first series of these bodies the action of light is essential, no elevation of temperature being capable of producing the chemical change. The following equations sufficiently exhibit the nature of the re-action :—

$$\underbrace{\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\}}_{\text{Iodide of methyl.}} + Hg = \underbrace{Hg\left\{\begin{matrix}C_2H_3\\I\end{matrix}\right.}_{\text{Methiodide of mercury.}}$$

$$\underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Hg = \underbrace{Hg\left\{\begin{matrix}C_4H_5\\I\end{matrix}\right.}_{\text{Ethiodide of mercury.}}$$

For the production of the methyl compound bright sunlight may be employed, but the re-action for the ethyl body must be conducted in diffused daylight only, otherwise no organometallic body will be produced, the ethyl being eliminated chiefly as such, but partly also as hydride of ethyl and ethylene.

In addition to these organometallic bodies, compounds containing arsenic and antimony can also be produced by this general mode of formation, but they are obtained with greater facility by the second method, which will now be described.

2. *Formation of organometallic bodies by the action of the respective metals alloyed with potassium or sodium upon the iodides of the alcohol radicals.*—The principles involved in this general mode of production are essentially similar to those in the first method, but there is here less tendency to form compounds containing negative as well as positive radicals. This method, although not capable of such general application, is more especially adapted for the formation of the organic compounds of the polyatomic metals. The simultaneous production of an organo-potassium or -sodium compound is not here to be feared, so long as the iodide of the alcohol radical is present in excess, because such compounds cannot exist in the presence of the iodides of the alcohol radicals.

This mode of formation will be sufficiently illustrated by the following re-actions :—

Arsenic Compounds.

$$\mathrm{Na_2As} + \underbrace{2\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{As}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Cacodyl.}} + \mathrm{2NaI}$$

$$\mathrm{Na_3As} + \underbrace{3\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{As}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Trimethylarsine}} + \mathrm{3NaI}$$

$$\mathrm{Na_3As} + \underbrace{4\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{As}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right.}_{\substack{\text{Iodide of}\\ \text{tetramethylarsonium.}}} + \mathrm{3NaI}$$

Antimony Compounds.

$$\mathrm{Na_3Sb} + \underbrace{3\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Trimethylstibine.}} + \mathrm{3NaI}$$

$$\mathrm{Na_3Sb} + \underbrace{4\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right.}_{\substack{\text{Iodide of}\\ \text{tetramethylstibonium.}}} + \mathrm{3NaI}$$

Tin Compounds.

$$\mathrm{2NaSn} + \underbrace{\mathrm{2C_2H_3I}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\substack{\text{Methide of tin}\\ \text{or stannous methide.}}} + \mathrm{2NaI}$$

$$\mathrm{Na_3Sn_2} + \underbrace{3\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Sequimethide of tin.}} + \mathrm{3NaI}$$

$$\mathrm{2Na_2Sn} + \underbrace{4\left.\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\substack{\text{Bimethide of tin,}\\ \text{or stannic methide.}}} + \mathrm{4NaI}$$

Lead Compounds.

$$\mathrm{Na_3Pb_2} + \underbrace{3\left.\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{I}\end{matrix}\right\}}_{\text{Iodide of ethyl.}} = \underbrace{\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Sesquiethide of lead.}} + \mathrm{3NaI}$$

Bismuth Compounds.

$$\mathrm{Na_3Bi} + \underbrace{\mathrm{3C_4H_5I}}_{\text{Iodide of ethyl.}} = \underbrace{\mathrm{Bi}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Bistriethyl.}} + \mathrm{3NaI}$$

Tellurium Compounds.

Organo-tellurium compounds are formed by a modification of this method, which consists in distilling telluride of potassium with sulphovinate of potash and its homologues.

$$\underbrace{\mathrm{2(C_2H_3O\,SO_3,\ KO\,SO_3)}}_{\text{Sulphomethylatcof potash.}} + \mathrm{2KTe} = \underbrace{\mathrm{Te_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Tellurium-methyl.}} + \mathrm{4KO\,SO_3}$$

$$\underbrace{\mathrm{2(C_4H_5O\,SO_3,\ KO\,SO_3)}}_{\text{Sulphovinate of potash.}} + \mathrm{2KTe} = \underbrace{\mathrm{Te_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Tellurium-ethyl.}} + \mathrm{4KO\,SO_3}$$

$$\underbrace{\mathrm{2(C_{10}H_{11}O\,SO_3,\ KO\,SO_3)}}_{\text{Sulphamylate of potash.}} + \mathrm{2KTe} = \underbrace{\mathrm{Te_2}\left\{\begin{matrix}\mathrm{C_{10}H_{11}}\\ \mathrm{C_{10}H_{11}}\end{matrix}\right.}_{\text{Tellurium-amyl.}} + \mathrm{4KO\,SO_3}$$

3. *Formation of organometallic bodies by the action of the zinc compounds of the organic radicals upon the haloid compounds, either of the metals themselves or of their organo-derivatives.*—For the production of organometallic bodies containing less positive metals than zinc, this method is perhaps not only the most convenient but also of the most general application. Organo-compounds containing mercury, tin, lead, antimony, and arsenic, have in this way been produced, but it has failed when applied to the haloid compounds of copper, silver, and platinum, for although these bodies are violently acted upon, the organic radical does not unite with the metals.

The following leading reactions represent the present state of our knowledge with regard to this method of formation :—

Tin Compounds.

$$\underbrace{\mathrm{2Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Zincethyl.}} + \mathrm{2SnCl_2} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Stannic ethide.}} + \mathrm{4ZnCl}$$

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Zincethyl.}} + \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{I}\\ \mathrm{I}\end{matrix}\right.}_{\text{Ethiodide of tin.}} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Stannic ethide.}} + \mathrm{2ZnI}$$

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Zincmethyl.}} + \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\\ \mathrm{I}\\ \mathrm{I}\end{matrix}\right.}_{\text{Ethiodide of tin.}} = \underbrace{\mathrm{Sn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\\ \mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\substack{\text{Stannic ethylo-}\\ \text{methide.}}} + \mathrm{2ZnI}$$

Mercury Compounds.

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Zincethyl.}} + \mathrm{HgCl_2} = \underbrace{\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Mercuric ethide.}} + \mathrm{2ZnCl}$$

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Mercuric ethide.}} + \mathrm{2Hg}\left\{\begin{matrix}\mathrm{Cl}\\ \mathrm{Cl}\end{matrix}\right. = \underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{Cl}\end{matrix}\right.}_{\text{Mercuric ethochloride.}} + \mathrm{2ZnCl}$$

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{C_2H_3}\end{matrix}\right.}_{\text{Zincmethyl.}} + \mathrm{2HgCl_2} = \underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\ \mathrm{Cl}\end{matrix}\right.}_{\text{Mercuric methochloride.}} + \mathrm{2ZnCl}$$

Mercurous ethide ($\mathrm{HgC_4H_5}$) and *mercurous methide* ($\mathrm{HgC_2H_3}$) have not yet been obtained, either by this or any other process. The instability of mercurous compounds, as seen in the inorganic oxide and iodide, is brought to a climax in organic mercurous compounds, they are instantly transformed into metallic mercury and the more stable organo-mercuric compounds. Thus when zincethyl acts upon mercurous chloride the following change results :

$$\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right. + \mathrm{2HgCl} = \mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right. + \mathrm{Hg} + \mathrm{2ZnCl}$$

Lead Compounds.

In this series, the following is the only reaction which has hitherto been effected by the method which we are now considering :—

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Zincethyl.}} + \mathrm{2PbCl} = \underbrace{\mathrm{Pb}\left\{\begin{matrix}\mathrm{C_4H_5}\\ \mathrm{C_4H_5}\end{matrix}\right.}_{\text{Plumbic ethide.}} + \mathrm{Pb} + \mathrm{2ZnCl}$$

4. *Formation of organometallic bodies by the displacement of a metal in organic combination by another and more positive metal.*—This mode of producing organometallic bodies has hitherto been applied only to the formation of sodium and potassium compounds, or rather double

compounds of these bodies with zincethyl, according to the following reactions:—

$$\underbrace{3Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + Na_2 = \underbrace{\left(2Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. + Na_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.\right)}_{\text{Double compound of sodiumethyl and zincethyl.}} + Zn_2$$

$$\underbrace{3Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + K_2 = \underbrace{\left(2Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. + K_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.\right)}_{\text{Potassiumethyl and zincethyl.}} + Zn_2$$

Sodium also displaces mercury from mercuric ethide; sodiumethyl appears to be formed, but the exact nature of the reaction has not been ascertained.

PROPERTIES OF ORGANOMETALLIC BODIES.

The organometallic compounds as a class are distinguished for the extraordinary energy of their affinities. With certain exceptions, presently to be noticed, their disposition to unite with negative elements increases with the positive character of the metal, and with the smallness of the atomic weight of the alcohol radical. Thus organo-potassium and sodium compounds possess more chemical energy than those of zinc, whilst the latter are more active than the organo-compounds of arsenic, antimony, tin, lead, &c. Again, in the family belonging to each metal, the methylic compounds are more energetic than the ethylic ones, whilst the last greatly surpass the amyl compounds in this respect. But whilst these general principles govern the chemical energy of organometallic bodies, their effect appears to be modified by the degree of saturation in which the metal exists. Although this circumstance has hitherto received only very partial elucidation, yet we have evidence of its existence in the case of the organo-tin compounds. Both stannous ethide and stannous methide combine directly with atmospheric oxygen, and the union takes place with tolerable rapidity, but neither stannic ethide nor stannic methide are in the least degree acted upon by free oxygen at ordinary temperatures; even iodine acts upon them with difficulty. This diminution of chemical energy in organostannic compounds cannot be ascribed to the mere influence of the additional weight of hydrocarbon which they contain, since stannous amylide readily unites with free oxygen at ordinary temperatures, although the single molecule of amyl which it contains is considerably heavier than the double atom of either methyl or ethyl contained in the organostannic compounds just cited.

Organometallic compounds in a state of partial saturation play the part of compound radicals. They are uniatomic, biatomic, teratomic, or quadratomic, according to the number of molecules requisite to complete their saturation. On the other hand, organometallic bodies in a state of saturation never perform radical functions, they never undergo chemical change without decomposition: thus zincethyl, stannic ethide, mercuric ethide, and plumbic ethide all give substitution products when they are chemically acted upon.

The description of the special properties of the organometallic bodies may be conveniently commenced with the most positive of the class, namely:—

Organo-potassium and sodium compounds.—These bodies have not yet been isolated, they are known only in combination with the corresponding zinc compounds. The double compound of sodiumethyl and zincethyl is the only one which has hitherto been submitted to analysis. Its formula is

$$Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. + NaC_4H_5$$

This compound first separates from its solution in zincethyl as a transparent fluid, which, after some time, solidifies to a mass of large tubular crystals, which fuse at 27° C., but when once fused, remain fluid at several degrees below that point. On the application of a moderate heat, gases are evolved, and a mixture of sodium and zinc without carbon is left behind. The double compound decomposes water with great violence, forming hydride of ethyl and hydrated oxides of zinc and sodium. The behaviour with negative elements has not yet been studied. Its most interesting reaction consists in the absorption of carbonic acid, which it transforms into propionic acid. The sodiumethyl alone takes part in this reaction.

$$\underbrace{NaC_4H_5}_{\text{Sodiumethyl.}} + C_2O_4 = \underbrace{\left.\begin{matrix}C_6H_5O_2\\Na\end{matrix}\right\}O_2}_{\text{Propionate of soda.}}$$

Similar double compounds, containing *sodiummethyl*, as well as the potassium compounds of ethyl and methyl, have been formed. They have not yet been completely investigated, but it is believed that their composition and properties are perfectly analogous to those of sodiumethyl.

No compound of any of these bodies with a negative element has been obtained. Their action upon carbonic acid proves that they possess a still higher reducing power than the corresponding organo-zinc compounds, and they will therefore doubtless prove valuable agents for the substitution of positive groups for negative elements in cases where organo-zinc compounds fail to produce the desired effect.

Sodiumethyl decomposes the iodides of the alcohol radicals in the cold, with the formation of iodide of sodium.

$$\underbrace{NaC_4H_5}_{\text{Sodiumethyl.}} + \underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} = NaI + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}} + \underbrace{C_4H_4}_{\text{Ethylene.}}$$

On this account, these bodies can only be prepared by method No 4.

Organo-magnesium compounds.—The compounds containing ethyl and methyl only have hitherto been examined, and the former alone submitted to analysis. These bodies possess a close similarity to organo-zinc compounds. They are very volatile colourless liquids possessing a powerful alliaceous odour, are spontaneously inflammable, and decompose water with violence. They do not readily decompose the iodides of the alcohol radicals, and can hence be prepared by the method No. 1. No compound of these bodies with negative elements has yet been produced. They are in the condition of chemical saturation. Further details of their properties are wanting.

Organo-aluminium compounds.—Like the organo-compounds of the alkaline metals, the aluminium compounds have not yet with certainty been isolated; they are only known in combination with iodide of aluminium, and the composition of the ethyl body only has been fixed by analysis. Its formula is

$$Al_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right. + Al_2\left\{\begin{matrix}I\\I\\I\end{matrix}\right.$$

These double compounds possess great chemical energy; they are spontaneously inflammable volatile liquids, which decompose water with explosive violence. They are attacked by zincethyl, forming iodide of zinc and very inflammable liquids, which are believed to be the pure organo-aluminium compounds. They appear to be chemically saturated bodies, and therefore incapable of direct combination. Further details are wanting.

Organo-glucinum compound.—The metal glucinum acts upon iodide ethyl, forming a liquid which rapidly decomposes water, and which is believed to be analogous to the double iodethide of aluminium above described, but it has not been further examined.

Organo-zinc compounds.—Three of these are more or less completely known, namely:—

Zincmethyl	$Zn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.$
Zincethyl	$Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.$
Zincamyl	$Zn_2\left\{\begin{matrix}C_{10}H_{11}\\C_{10}H_{11}\end{matrix}\right.$

They are colourless, transparent, mobile, volatile, and odorous liquids, composed of 4 gaseous volumes of the hydrocarbon radical, and 2 volumes of zinc vapour, the six volumes condensed to 4. The methyl and ethyl compounds are spontaneously inflammable, burning with a greenish-blue flame. All three are saturated compounds, incapable of direct combination. In contact with water they are instantly decomposed with the formation of oxide of zinc, and hydride of the organic radical. Thus zincethyl suffers the following decomposition:—

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + \left.\begin{matrix}H\\H\end{matrix}\right\}O_2 = \left.\begin{matrix}Zn\\Zn\end{matrix}\right\}O_2 + \underbrace{2\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

Gradually treated with oxygen, so as to avoid too violent action, they form the respective zinc alcohols:—

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + O_4 = \underbrace{2\left.\begin{matrix}C_4H_5\\Zn\end{matrix}\right\}O_2}_{\text{Ethylate of zinc.}}$$

The action of iodine upon organo-zinc compounds consists in the transformation of both their constituents into iodides:—

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + I_4 = 2ZnI + \underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}}$$

Organo-zinc compounds behave in a manner exactly analogous in contact with the other halogens.

Reactions like the foregoing point to the applicability of organo-zinc compounds for effecting the substitution of positive groups for negative elements in compound bodies; an application which has not failed to attract the notice of chemists. In addition to re-actions of this class, given above, as examples of the formation of organometallic bodies by the third method, the following have been realised:—

Binoxide of Nitrogen.

$$\underbrace{2(N_2O_4)}_{\text{Binoxide of nitrogen.}} + \underbrace{Zn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.}_{\text{Zincmethyl.}} = \underbrace{2\left.\begin{matrix}N_2C_2H_3O_2\\Zn\end{matrix}\right\}O_2}_{\text{Dinitromethylate of zinc.}}$$

$$\underbrace{2(N_2O_4)}_{\text{Binoxide of nitrogen.}} + Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. = \underbrace{2\left.\begin{matrix}N_2C_4H_5O_2\\Zn\end{matrix}\right\}O_2}_{\text{Dinitroethylate of zinc.}}$$

It will be perceived that this re-action is the exact analogue of the one already mentioned in connection with organo-sodium and potassium compounds, in which carbonic acid, treated with sodium methyl and sodium ethyl forms acetic and propionic acids: in fact, dinitromethylic and dinitroethylic acids may be regarded as the analogues of acetic and propionic acids respectively; the nitrogen, here sustaining a biatomic character, replacing an equivalent amount of carbon.

Sulphurous Acid.

$$\underbrace{4(SO_2)}_{\text{Sulphurous acid.}} + \underbrace{Zn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.}_{\text{Zincmethyl.}} = \underbrace{2\left.\begin{matrix}S_2C_2H_3O_2\\Zn\end{matrix}\right\}O_2}_{\text{Methylodithionate of zinc.}}$$

$$\underbrace{6(SO_2)}_{\text{Sulphurous acid.}} + \underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} = \underbrace{2\left.\begin{matrix}S_2C_4H_5O_4\\Zn\end{matrix}\right\}O_2}_{\text{Ethylotrithionate of zinc.}}$$

Chloride of Phosphorus.

$$\underbrace{2(PCl_3)}_{\text{Terchloride of phosphorus.}} + \underbrace{3Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} = \underbrace{2P\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Triethylphosphine.}} + 6ZnCl$$

There is no apparent obstacle to this reaction being pushed to its extreme limit in the case of pentatomic bodies, such as phosphorus, arsenic, or antimony. Mr. Buckton has recently attempted this in the case of antimony, but although evidence of the existence of a pentethide of antimony was obtained, the body could not be isolated and its composition satisfactorily fixed. The greater stability of the triatomic compounds of these bodies will probably present considerable difficulty in the way of obtaining pentatomic compounds of an exclusively positive character, such bodies being doubtless easily resolved into the more stable groupings represented in the following equation:

$$\underbrace{Sb\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Pentethide of antimony.}} = \underbrace{Sb\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Triethylstibine.}} + \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}}_{\text{Ethyl.}}$$

Whilst on the one hand organo-zinc compounds are thus capable of effecting the substitution of their positive organic group for negative elements, on the other they can in certain cases replace hydrogen by zinc, forming, with ammonia and its homologues, for instance, a series of zincamides. In this direction the following reactions, amongst others, have been recorded.

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + \underbrace{2N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.}_{\text{Ammonia.}} = \underbrace{2N\left\{\begin{matrix}H\\H\\Zn\end{matrix}\right.}_{\text{Zincamide.}} + \underbrace{2\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + \underbrace{2N\left\{\begin{matrix}C_4H_5\\C_4H_5\\H\end{matrix}\right.}_{\text{Diethylamine.}} = \underbrace{2N\left\{\begin{matrix}C_4H_5\\C_4H_5\\Zn\end{matrix}\right.}_{\text{Diethylzinc-amide.}} + \underbrace{2\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

$$\underbrace{Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Zincethyl.}} + \underbrace{N_2\left\{\begin{matrix}C_4O_4''\\H_2\\H_2\end{matrix}\right.}_{\text{Oxamide.}} = \underbrace{N_2\left\{\begin{matrix}C_4O_4''\\H_2\\Zn_2\end{matrix}\right.}_{\text{Zincoximide.}} + \underbrace{2\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

The members of the zinc series unite with neutral salts to form compounds which have been but little examined. The following however are known:

Dinitromethylate of zinc and zincmethyl .	$2\left.\begin{matrix}N_2C_2H_3O_2\\Zn\end{matrix}\right\}O_2 + Zn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.$
Dinitroethylate of zinc and zincethyl . .	$2\left.\begin{matrix}N_2C_4H_5O_2\\Zn\end{matrix}\right\}O_2 + Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.$

Finally, it has been observed that zincmethyl, when generated in contact with methylic or vinic ether, combines with these bodies, forming

Methylate of zincmethyl . .	$2\left(Zn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.\right) + \left.\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right\}O_2$
Ethylate of zincethyl . . .	$2\left(Zn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.\right) + \left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2$

Cadmium Series.—Only one member of this series is known, and that very imperfectly. So far as its properties have been made out, they appear to be perfectly analogous to those of the zinc series.

Tin Series.—A large number of organometallic bodies containing tin have been described. The existence of the following may be considered as clearly established.

a. Stannous Compounds.

Stannous methide or stanmethyl . . .	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.$
Stannous ethide or stanethyl	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.$

b. Sesqui Compounds.

Sesquimethide of tin	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\end{matrix}\right.$
Sesquiethide of tin	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.$
Sesquidimethiodide of tin	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\I\end{matrix}\right.$
Sesquidiethiodide of tin	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\end{matrix}\right.$

c. Stannic Compounds.

Stannic methide	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\end{matrix}\right.$
Stannic ethide	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.$
Stannic ethylodimethide	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_4H_5\\C_4H_5\end{matrix}\right.$
Stannic ethylotrimethide	$Sn_2\left\{\begin{matrix}C_4H_5\\C_2H_3\\C_2H_3\\C_2H_3\end{matrix}\right.$
Trimethiodide of tin	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\\I\end{matrix}\right.$
Triethiodide of tin	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.$
Dimethiodide of tin or iodide of stanmethyl .	$Sn_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\I\\I\end{matrix}\right.$
Diethiodide of tin or iodide of stanethyl . .	$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.$

It is scarcely necessary to observe that the iodine in the above compounds admits of replacement by any salt-forming radical, and also by oxygen or sulphur.

Stannous Compounds are oily liquids, possessing a pungent odour, soluble in alcohol and ether, but insoluble in water. They cannot be distilled without decomposition, being resolved into stannic compounds and metallic tin. Stannous compounds are in a state of partial chemical saturation only, they therefore perform the part of radicals, combining directly with chlorine, oxygen, &c. and forming well marked bodies of great stability.

The stannous compounds represented by the above formulæ are biatomic, and unite directly with free oxygen, chlorine, &c. to produce bodies of the stannic form. Thus, stannous ethide forms with oxygen stannic diethoxide:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Stannous ethide.}} + O_2 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\O\\O\end{matrix}\right.}_{\text{Stannic diethoxide.}}$$

Stannous compounds have never yet been observed to play a uniatomic part. No sesquicompound has been directly formed from a stannous body, the latter under the influence of iodine, oxygen, &c. seems to pass at once into the stannic form. It must be remarked, however, that no direct experiments have been made with a view of revealing any uniatomic attribute which may attach to stannous compounds.

Sesquicompounds of the form $Sn_2\left\{\begin{matrix}R+\\R+\\R+\end{matrix}\right.$ have hitherto been very little examined, they are oily liquids uniting directly with negative radicals, and forming extensive series of compounds belonging to the stannic class, a considerable number of which have been studied. The following examples will serve to show the mode in which sesquicompounds of this form pass into bodies of the stannic class:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Sesquiethide of tin.}} + I = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Stannic triethiodide.}}$$

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Stannic triethiodide.}} + I_2 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.}_{\text{Stannic diethiodide.}} + \underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}}$$

No reduction of a sesqui to a stannous compound has yet been effected, although it can scarcely be doubted that an aqueous solution of sesquidiethiodide of tin, for instance, if treated with zinc, would yield stannous ethide. On the other hand, an instance of the reduction of a stannic to a sesquicompound has been observed. Thus stannic ethylodimethide in contact with iodine is transformed into sesquidiethiodide of tin.

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_2H_3\\C_2H_3\end{matrix}\right.}_{\text{Stannic ethylodimethide.}} + I_2 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Sesquidiethiodide of tin.}} + \underbrace{2C_2H_3I}_{\text{Iodide of methyl.}}$$

Sesquicompounds of the form $Sn_2\left\{\begin{matrix}R+\\R+\\R-\end{matrix}\right.$ are very little known; in fact the sesquidiethiodide of tin $\left(Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\end{matrix}\right.\right)$, the production of which from stannic ethylodimethide has just been mentioned, is the only one known with certainty. It is a colourless mobile liquid, possessing a most insupportable odour, like essential oil of mustard, and boiling with partial decomposition at a high temperature. Heated with an excess of iodine, it is transformed into stannic diethiodide:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Sesquidiethiodide of tin.}} + I = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.}_{\text{Stannic diethiodide.}}$$

Stannic compounds of the form $Sn_2\left\{\begin{matrix}R+\\R+\\R+\\R+\end{matrix}\right.$ are colourless mobile liquids, possessing a slight ethereal odour. They are volatile without decomposition, and possess great stability. Being in the condition of chemical saturation they are incapable of direct combination. No body can act upon them without expelling one or more equivalents of positive radical. Thus, when heated with hydrochloric acid, stannic ethide yields stannic triethochloride and hydride of ethyl:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Stannic ethide.}} + HCl = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\Cl\end{matrix}\right.}_{\text{Stannic triethochloride.}} + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

With two equivalents of iodine the reaction is:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Stannic ethide.}} + I_2 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.}_{\text{Stannic triethiodide.}} + \underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}}$$

And with four equivalents of iodine:

$$\underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Stannic ethide.}} + I_4 = \underbrace{Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.}_{\text{Stannic diethiodide.}} + 2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}$$

Stannic compounds of the form $Sn_2\left\{\begin{matrix}R+\\R+\\R+\\R-\end{matrix}\right.$ commonly called compounds of sesquistanethyl, have been comparatively well studied. The oxides are, in the anhydrous condition, volatile limpid oily liquids, which readily unite with water, forming crystalline hydrates possessing a powerful alkaline reaction, and neutralising the strongest acids, with which they form an extensive series of salts. These salts are also all soluble in water, readily crystallisable, and possess a pungent odour. The stannic triethiodide and the sulphate of sesquistanethyl may be adduced as examples of the haloid and oxysalts respectively.

Stannic triethiodide . . . . . $Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\I\end{matrix}\right.$

Stannic triethylosulphate . . . . . $Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\SO_4\end{matrix}\right.$

Stannic compounds of the form $Sn_2\left\{\begin{matrix}R+\\R+\\R-\\R-\end{matrix}\right.$ have also been very completely investigated. The oxides are white amorphous powders, insoluble in water, alcohol, and ether. They dissolve in hydrochloric, hydriodic, and hydrobromic acids, forming colourless and inodorous salts crystallising in fine prisms. Most of the oxysalts can also be obtained in the crystalline form, either from aqueous or alcoholic solutions. The iodide and sulphate of stannic diethide, which may be regarded as representatives of the haloid and oxysalts, have the following formulæ:

Iodide of stannic diethide . . . . $Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\I\\I\end{matrix}\right.$

Sulphate of stannic diethide . . . . $Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\SO_4\\SO_4\end{matrix}\right.$

Stannic compounds of this form are readily reduced to stannous compounds; thus, when a piece of zinc is plunged into a solution of stannic diethochloride, stannous ethide is produced:

$$Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\Cl\\Cl\end{matrix}\right. + Zn_2 = Sn_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right. + 2ZnCl$$

Bismuth Series.—The following bodies belonging to this series have been described:

1. Bismuthous ethide . . . . $Bi\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.$
2. Bismuthous dichlorethide . . . . $Bi\left\{\begin{matrix}C_4H_5\\Cl\\Cl\end{matrix}\right.$
3. Bismuthous diiodoethide . . . $Bi\left\{\begin{matrix}C_4H_5\\I\\I\end{matrix}\right.$
4. Bismuthous dioxyethide . . . . $Bi\left\{\begin{matrix}C_4H_5\\O\\O\end{matrix}\right.$?
5. Double compound of bismuthous sulphide with bismuthic disulphethide . . . . . $Bi\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\S\\S\end{matrix}\right. + 2BiS_3$?

These bodies have as yet been only very imperfectly investigated. Bismuthous ethide is a colourless or slightly yellow mobile liquid, having an unpleasant odour like stibethine. Exposed to the air it gives off dense yellow fumes, inflames spontaneously, and finally explodes. It is very instable, begins to decompose at 50° to 60° C., and explodes violently when heated to 150° C., a temperature still below its boiling point. No direct compound of this body has yet been obtained; it behaves like a chemically saturated substance, and when slowly oxidised in contact with water, yields alcohol and hydrated oxide of bismuth.

$$Bi\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right. + 3\left.\begin{matrix}H\\H\end{matrix}\right\}O_2 + O_6 = BiO_3, 3HO + 3\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2$$

When an alcoholic solution of bichloride of mercury is added to an alcoholic solution of bismuthous ethide, mercuric etho-chloride crystallises out, whilst bismuthous dichlorethide remains in solution:

$$\underbrace{Bi\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Bismuthous ethide.}} + 2HgCl_2 = \underbrace{Bi\left\{\begin{matrix}C_4H_5\\Cl\\Cl\end{matrix}\right.}_{\text{Bismuthous dichlorethide.}} + \underbrace{2Hg\left\{\begin{matrix}C_4H_5\\Cl\end{matrix}\right.}_{\text{Mercuric ethochloride.}}$$

From the bismuthous dichlorethide, the biniodide and binoxide are prepared by double decomposition; whilst the simultaneous action of sulphuretted hydrogen, water, bismuthous triethide and atmospheric oxygen is said to produce the double compound of bismuthous sulphide and bismuthic disulphethide.

Lead series.—The following bodies are known, the ethyl group alone having been explored.

Diplumbotriethyl	$\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\ ?\\\mathrm{C_4H_5}\end{matrix}\right.$
Oxide of diplumbotriethyl	$\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{O}\end{matrix}\right.$
Chloride of diplumbotriethyl	$\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{Cl}\end{matrix}\right.$
Sulphate of diplumbotriethyl	$\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{SO_4}\end{matrix}\right.$
Plumbic ethide	$\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\end{matrix}\right.$

The existence of the first of these bodies cannot be said to be clearly established, but by the action of an alloy of sodium and lead upon iodide of ethyl, a colourless mobile volatile liquid is obtained, which, when dissolved in alcohol or ether, and exposed to the air, forms the oxide of diplumbotriethyl, a body which, however, is more readily obtained by the decomposition of the chloride with oxide of silver.

$$\underbrace{\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{Cl}\end{matrix}\right.}_{\text{Chloride of diplumbotriethyl.}} + \mathrm{AgO} = \underbrace{\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{O}\end{matrix}\right.}_{\text{Oxide of diplumbotriethyl.}} + \mathrm{AgCl}$$

Plumbic ethide is a colourless limpid fluid with a faint odour, soluble in ether, but insoluble in water. It is not acted upon by oxygen at ordinary temperatures, but chlorine, bromine, and iodine act violently upon it. Plumbic ethide belongs to the class of saturated bodies, and is consequently incapable of forming compounds. Treated with hydrochloric acid, hydride of ethyl separates, and chloride of plumbotriethide is formed.

$$\underbrace{\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\end{matrix}\right.}_{\text{Plumbic ethide.}} + \mathrm{HCl} = \underbrace{\mathrm{Pb_2}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{C_4H_5}\\\mathrm{Cl}\end{matrix}\right.}_{\text{Chloride of diplumbotriethyl.}} + \underbrace{\left.\begin{matrix}\mathrm{C_4H_5}\\\mathrm{H}\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

From the plumbotriethide the sulphate and other salts can be prepared by double decomposition. These salts may also be obtained still more readily from the oxide, which is a crystalline volatile pungent body, possessing a powerful alkaline reaction, and attracting carbonic acid from the air.

Mercury series.—This series is confined to bodies of the mercuric type, no organo-mercurous compound having been yet produced. It comprises the following members:—

Mercuric methiodide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{I}\end{matrix}\right.$
Hydrate of mercuric methoxide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{HO_2}\end{matrix}\right.$
Nitrate of mercuric methoxide . . .	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{NO_6}\end{matrix}\right.$
Mercuric methide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.$
Mercuric ethiodide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{I}\end{matrix}\right.$
Hydrate of mercuric ethoxide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{HO_2}\end{matrix}\right.$
Nitrate of mercuric ethoxide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{NO_6}\end{matrix}\right.$
Mercuric ethide, or hydrargethyl	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\end{matrix}\right.$
Mercuric ethylomethide	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_4H_5}\end{matrix}\right.\ ?$
Mercury allyl	$\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_6H_5}\\\mathrm{C_6H_5}\end{matrix}\right.$

Mercuric methide and mercuric-ethide are colourless ethereal volatile bodies, insoluble in water, but soluble in alcohol and ether, and possessing great stability. They are in a state of maximum saturation and cannot therefore unite with any other body without the expulsion of an equivalent of positive radical: thus with bromine, mercuric ethide gives bromide of ethyl and mercuric ethylobromide:

$$\underbrace{\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_4H_5}\end{matrix}\right.}_{\text{Mercuric ethyl.}} + \mathrm{2Br} = \underbrace{\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{Br}\end{matrix}\right.}_{\text{Mercuric ethylobromide.}} + \underbrace{\left.\begin{matrix}\mathrm{C_4H_5}\\\mathrm{Br}\end{matrix}\right\}}_{\text{Bromide of ethyl.}}$$

Mercuric methide possesses the highest specific gravity of any known non-metallic liquid (3·069). Glass consequently floats upon its surface. Brought into contact with mercuric iodide, mercuric methide and mercuric ethide are converted respectively into mercuric methiodide and mercuric ethiodide. Thus mercuric methide gives—

$$\underbrace{\mathrm{Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.}_{\text{Mercuric methide.}} + \mathrm{Hg}\left\{\begin{matrix}\mathrm{I}\\\mathrm{I}\end{matrix}\right. = \underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{I}\end{matrix}\right.}_{\text{Mercuric methiodide.}}$$

The reaction with bichloride of mercury is exactly analogous.

The hydrates of mercuric methoxide and mercuric ethoxide are caustic alkaline bases capable of expelling ammonia from its salts, and behaving in a manner similar to the corresponding uniatomic compounds of tin and lead. The remaining mercury compounds which may be considered as derivatives of these two bodies, are represented in the above list by the iodides and nitrates; they generally crystallise very readily, and, with the exception of the haloid compounds, are soluble in water. When their aqueous solutions are treated with zinc they are decomposed, the zinc becomes amalgamated, and gaseous hydrides of the positive radicals are evolved. It is highly probable that there are two stages in this reaction, organozinc compounds being first formed and then decomposed by contact with water, thus with mercuric methiodide—

$$\underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{I}\end{matrix}\right.}_{\text{Mercuric methiodide.}} + \mathrm{Zn_4} = \underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.}_{\text{Zincmethyl.}} + \mathrm{2ZnI} + \mathrm{2Hg}$$

and then:

$$\underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.}_{\text{Zincmethyl.}} + \underbrace{\left.\begin{matrix}\mathrm{H}\\\mathrm{H}\end{matrix}\right\}\mathrm{O_2}}_{\text{Water.}} = \underbrace{2\left.\begin{matrix}\mathrm{C_2H_3}\\\mathrm{H}\end{matrix}\right\}}_{\text{Hydride of methyl.}} + \mathrm{2ZnO}$$

This view of the reaction is confirmed by the fact that when zinc acts upon mercuric methiodide at 150° C., zincmethyl is produced.

When one of the above iodides, or the corresponding chloride or bromide, is treated with an organozinc compound, the negative element becomes replaced by the alcohol radical of the zinc compound; thus when mercuric methiodide is treated with zincmethyl, mercuric methide is produced, and it is believed that by acting upon mercuric ethochloride with zincmethyl, mercuric ethylomethide is produced.

$$\underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{Cl}\end{matrix}\right.}_{\text{Mercuric ethochloride.}} + \underbrace{\mathrm{Zn_2}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.}_{\text{Zincmethyl.}} = \underbrace{\mathrm{2Hg}\left\{\begin{matrix}\mathrm{C_4H_5}\\\mathrm{C_2H_3}\end{matrix}\right.}_{\text{Mercuric ethylomethide.}} + \mathrm{2ZnCl}$$

but this body has not yet been obtained in a state of purity. Distillation gradually resolves it into mercuric methide and mercuric ethide:—

Antimony series.—This series of organometallic bodies contains a greater number and variety of compounds than any other with the exception of arsenic. The remarkable polyatomic character of antimony and arsenic not only renders the possible number of their organo-compounds very large, but the variation in the proportions of the positive and negative molecules gives an extremely wide range to their chemical character, extending as it does from highly caustic bases on the one hand to powerful bibasic acids on the other. The following are the principal compounds belonging to this series:—

Trimethylstibine	$\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\end{matrix}\right.$
Antimonic trimethyloxide	$\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{O}\\\mathrm{O}\end{matrix}\right.$
Antimonic trimethylchloride	$\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{Cl}\\\mathrm{Cl}\end{matrix}\right.$
Iodide of tetramethylstibonium	$\mathrm{Sb}\left\{\begin{matrix}\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{C_2H_3}\\\mathrm{I}\end{matrix}\right.$

Antimonic trimethylosulphate	$\mathrm{Sb}\begin{cases}C_2H_3\\C_2H_3\\C_2H_3\\SO_4\\SO_4\end{cases}$
Sulphate of tetramethylstibonium	$\mathrm{Sb}\begin{cases}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\\SO_4\end{cases}$
Triethylstibine	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\end{cases}$
Antimonic triethyloxide	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\O\\O\end{cases}$
Antimonic triethylchloride	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\Cl\\Cl\end{cases}$
Iodide of tetraethylstibonium	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\\I\end{cases}$
Iodide of methylotriethylstibonium	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\C_2H_3\\I\end{cases}$
Antimonic triethylosulphate	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\SO_4\\SO_4\end{cases}$
Sulphate of tetraethylostibonium	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\\SO_4\end{cases}$
Antimonic triethylantiomonite	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\SbO_4\\SbO_4\end{cases}$
Antimonic triethyloxyiodide	$\mathrm{Sb}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\O\\I\end{cases}$
Triamylstibine	$\mathrm{Sb}\begin{cases}C_{10}H_{11}\\C_{10}H_{11}\\C_{10}H_{11}\end{cases}$
Antimonic triamylchloride	$\mathrm{Sb}\begin{cases}C_{10}H_{11}\\C_{10}H_{11}\\C_{10}H_{11}\\Cl\\Cl\end{cases}$
Antimonic triamylnitrate	$\mathrm{Sb}\begin{cases}C_{10}H_{11}\\C_{10}H_{11}\\C_{10}H_{11}\\NO_6\\NO_6\end{cases}$

It is remarkable that we have as yet no decisive evidence of the existence in this series of a compound corresponding to cacodyl. It is true that such a body has been described under the name of *stibbiamyl*, but subsequent experiments have failed to confirm its existence. Amongst organo-antimony compounds, therefore, the most simple form is $\mathrm{Sb}\begin{cases}R+\\R+\\R+\end{cases}$ bodies of this form, and of the type $\mathrm{Sb}\begin{cases}R+\\R+\\R+\\R+\\R-\end{cases}$ are the analogues of ammonia and its derivatives; for a description of them, see ORGANIC BASES.

The only bodies therefore of this series requiring notice here are those of the form $\mathrm{Sb}\begin{cases}R+\\R+\\R+\\R-\\R-\end{cases}$ and their derivatives. When the two atoms of negative radical are oxygen, these compounds constitute what may be termed biacid antimony bases. They are formed either by the direct union of the stibamines $\left(\mathrm{Sb}\begin{cases}R+\\R+\\R+\end{cases}\right)$ with oxygen,

$$\mathrm{Sb}\begin{cases}R+\\R+\\R+\end{cases} + O_2 = \mathrm{Sb}\begin{cases}R+\\R+\\R+\\O\\O\end{cases}$$

or by the decomposition of the corresponding haloid compounds by means of potash, thus—

$$\mathrm{Sb}\begin{cases}R+\\R+\\R+\\Cl\\Cl\end{cases} + 2KO = \mathrm{Sb}\begin{cases}R+\\R+\\R+\\O\\O\end{cases} + 2KCl$$

The stibamines, although in other respects the perfect analogues of the nitramines, here exhibit a much more highly positive character, uniting with oxygen so energetically as to be spontaneously inflammable in the lower portion of the series.

The biacid antimony bases are colourless, transparent, amorphous, and tenacious bodies, the ethylic base is easily soluble in water and alcohol, but somewhat less soluble in ether. They possess a bitter taste, are non-volatile, and do not suffer any change when exposed to the air. Treated with potassium they are reduced to stibamines.

$$\mathrm{Sb}\begin{cases}R+\\R+\\R+\\O\\O\end{cases} + 2K = \mathrm{Sb}\begin{cases}R+\\R+\\R+\end{cases} + 2KO$$

Fuming nitric acid decomposes the biacid bases with ignition, but when treated with dilute nitric acid, or other acid, the respective biacid salts are produced. The oxysalts are soluble in water and alcohol, most of them crystallise without much difficulty, as does also the biniodide, but the bibromide and bichloride of the ethylic base are liquids not volatile without decomposition, insoluble in water, but soluble in alcohol and ether.

Arsenic series.—This series is perhaps the most important and interesting amongst organo metallic bodies; it contains the first discovered organo-metal, Cacodyl, the classical investigation of which by Bunsen, imparts not merely a completeness to our knowledge of this series, but has afforded the clue to the successful interpretation of many phenomena met with in other analogous series. It will be convenient to divide its very numerous members into three groups:—

A. Organo-arsenical compounds of the type . $\mathrm{As}\begin{cases}R\\R\end{cases}$

B. Organo-arsenical compounds of the type . $\mathrm{As}\begin{cases}R\\R\\R\end{cases}$

C. Organo-arsenical compounds of the type . $\mathrm{As}\begin{cases}R\\R\\R\\R\\R\end{cases}$

All arsenical compounds permit of being arranged under these three types. The following are the principal bodies already investigated:—

A. *Organo-arsenical compounds of the type* $\mathrm{As}\begin{cases}R\\R\end{cases}$

Cacodyl	$\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\end{cases}$
Ethylic cacodyl	$\mathrm{As}\begin{cases}C_4H_5\\C_4H_5\end{cases}$

B. *Organo-arsenical compounds of the type* $\mathrm{As}\begin{cases}R\\R\\R\end{cases}$

Oxide of cacodyl	$\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\O\end{cases}$
Chloride of cacodyl	$\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\Cl\end{cases}$
Chloride of cacoplatyl	$\mathrm{As}\begin{cases}C_2H_3\\C_2Pt''H\\Cl\end{cases}$
Arsenious dioxymethide	$\mathrm{As}\begin{cases}C_2H_3\\O\\O\end{cases}$
Arsenious dichlormethide	$\mathrm{As}\begin{cases}C_2H_3\\Cl\\Cl\end{cases}$
Trimethylarsine	$\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\C_2H_3\end{cases}$

Triethylarsine . . . . $\mathrm{As}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\end{cases}$

C. *Organo-arsenical compounds of the type* $\mathrm{As}\begin{cases}R\\R\\R\\R\\R\end{cases}$

This group may be conveniently sub-divided into four families, namely:

a. Bodies of the form $\mathrm{As}\begin{cases}R+\\R-\\R-\\R-\\R-\end{cases}$ and their derivatives.

b. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R-\\R-\\R-\end{cases}$ and their derivatives.

c. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R+\\R-\\R-\end{cases}$ and their derivatives.

d. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R+\\R+\\R-\end{cases}$ and their derivatives.

a. Bodies of the form $\mathrm{As}\begin{cases}R+\\R-\\R-\\R-\\R-\end{cases}$

Monomethylarsenic acid . . . . . . $\mathrm{As}\begin{cases}C_2H_3\\O\\O\\O\\O\end{cases}$

Monomethylarseniates . . . . $\mathrm{As}\begin{cases}C_2H_3\\O\\O\\MO_2\\MO_2\end{cases}$

Arsenic dioxydichlormethide . . . . $\mathrm{As}\begin{cases}C_2H_3\\Cl\\Cl\\O\\O\end{cases}$

b. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R-\\R-\\R-\end{cases}$

Cacodylic acid . . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\O\\O\\O\end{cases}$

Cacodylates . . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\O\\O\\MO_2\end{cases}$

Terchloride of cacodyl. . . . . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\Cl\\Cl\\Cl\end{cases}$

c. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R+\\R-\\R-\end{cases}$

Arsenic triethyloxide . . . . . $\mathrm{As}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\O\\O\end{cases}$

Arsenic triethyliodide . . . . . . $\mathrm{As}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\I\\I\end{cases}$

d. Bodies of the form $\mathrm{As}\begin{cases}R+\\R+\\R+\\R+\\R-\end{cases}$

Oxide of tetramethylarsonium . . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\\O\end{cases}$

Iodide of tetramethylarsonium . . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\\I\end{cases}$

Oxide of dimethyl-diethyl-arsonium . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\C_4H_5\\C_4H_5\\O\end{cases}$

Chloride of tetrethylarsonium . . . . $\mathrm{As}\begin{cases}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\\Cl\end{cases}$

Iodide of dimethyl-diamyl-arsonium . . . $\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\C_{10}H_{11}\\C_{10}H_{11}\\I\end{cases}$

The organo-arsenical compounds belonging to the type $\mathrm{As}\begin{cases}R\\R\end{cases}$ contain only positive radicals. They are volatile poisonous liquids, insoluble in water, but very soluble in alcohol and ether, possessing an insupportable odour. The lower members of the family are spontaneously inflammable, whilst the higher ones also rapidly oxidise in air. They unite with negative elements with great energy, manifesting in their combinations either a uniatomic or a teratomic character, and producing bodies respectively of the forms $\mathrm{As}\begin{cases}R+\\R+\\-\end{cases}$ and $\mathrm{As}\begin{cases}R+\\R+\\R-\\R-\\R-\end{cases}$. Thus cacodyl forms with chlorine, chloride of cacodyl and terchloride of cacodyl.

$$\underbrace{\mathrm{As}(C_2H_3)_2}_{\text{Cacodyl.}} + Cl = \underbrace{\mathrm{As}(C_2H_3)_2Cl}_{\text{Chloride of cacodyl.}}$$

$$\underbrace{\mathrm{As}(C_2H_3)_2}_{\text{Cacodyl.}} + Cl_2 = \underbrace{\mathrm{As}(C_2H_3)_2Cl_3}_{\text{Terchloride of cacodyl.}}$$

Methylic cacodyl boils at 338° F., and ethylic cacodyl between 365° and 374°.

Heated to 750°, cacodyl splits up into metallic arsenic, hydride of methyl, and olefiant gas.

$$\underbrace{2\mathrm{As}(C_2H_3)_2}_{\text{Cacodyl.}} = \mathrm{As}_2 + \underbrace{2\left.\begin{matrix}C_2H_3\\H\end{matrix}\right\}}_{\text{Hydride of methyl.}} + \underbrace{C_4H_4}_{\text{Olefiant gas.}}$$

Bodies of this type can be regenerated from many of their uniatomic compounds by reducing agents; thus chloride of cacodyl and metallic zinc give cacodyl and chloride of zinc:—

$$\underbrace{\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\\Cl\end{cases}}_{\text{Chloride of cacodyl.}} + Zn = \underbrace{\mathrm{As}\begin{cases}C_2H_3\\C_2H_3\end{cases}}_{\text{Cacodyl.}} + ZnCl$$

Organo-arsenical compounds of the type $\mathrm{As}\begin{cases}R\\R\\R\end{cases}$ are of three forms, namely—

$$\mathrm{As}\begin{cases}R+\\R+\\R+\end{cases} \quad \mathrm{As}\begin{cases}R+\\R+\\R-\end{cases} \quad \mathrm{As}\begin{cases}R+\\R-\\R-\end{cases}$$

Those belonging to the first are termed *arsines,* and are the analogues of ammonia, but like the corresponding antimony compounds, in addition to their alkaloid functions they have the power of combining with two negative atoms, forming bodies of the sub-type

$$\mathrm{As}\begin{cases}R+\\R+\\R+\\R-\\R-\end{cases}$$

Thus triethylarsine combines with oxygen to form arsenic dioxyethide.

The lower members of this type possess this power to such an extent as to render them spontaneously inflammable in air.

Compounds belonging to the second of the above sub-types are produced by the direct combinations of the cacodyles with negative elements, the oxides are bases of comparatively feeble power, slowly combining with two additional equivalents of oxygen to form acids. Thus oxide of cacodyl by exposure to air slowly passes into cacodylic acid :—

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\O\end{matrix}\right.}_{\text{Oxide of cacodyl.}} + O_2 = \underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\O\\O\\O\end{matrix}\right.}_{\text{Cacodylic acid.}}$$

The chlorine, bromine, and iodine compounds of this type are volatile neutral bodies, which may be regarded as the haloid salts of cacodyl. Heated in contact with bichloride of platinum, the chloride of cacodyl presents an interesting reaction; two equivalents of hydrogen in the cacodyl become replaced by a biatomic molecule of platinum, producing chloride of cacoplatyl :—

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\Cl\end{matrix}\right.}_{\text{Chloride of cacodyl.}} + PtCl_2 = \underbrace{As\left\{\begin{matrix}C_2H_3\\C_2Pt'H\\Cl\end{matrix}\right.}_{\text{Chloride of cacoplatyl.}} + 2HCl$$

Cacoplatyl forms a series of compounds analogous to those of cacodyl.

The only compounds of the third form yet known belong to the methylic group. Arsenious dioxymethide is a crystalline body of a neutral character, soluble in water, alcohol, and ether; unchanged by exposure to air, but transformed by distillation with hydrate of potash into arsenious acid and oxide of cacodyl.

$$2As\left\{\begin{matrix}C_2H_3\\O\\O\end{matrix}\right. = AsO_3 + As\left\{\begin{matrix}C_2H_3\\C_2H_3\\O\end{matrix}\right.$$

Hydrochloric acid converts it into arsenious dichlormethide

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\O\\O\end{matrix}\right.}_{\text{Arsenious dioxymethide.}} + 2HCl = \underbrace{As\left\{\begin{matrix}C_2H_3\\Cl\\Cl\end{matrix}\right.}_{\text{Arsenious dichlormethide.}} + \left.\begin{matrix}H\\H\end{matrix}\right\}O_2$$

Hydrobromic and hydriodic acids produce a perfectly analogous change, whilst sulphuretted hydrogen transforms it into arsenious disulphomethide. The chlorine compound can also be formed by heating arsenic trichlormethide to 122° F.

$$\underbrace{As(C_2H_3)_2Cl_3}_{\text{Arsenic trichlormethide.}} = \underbrace{As(C_2H_3)Cl_2}_{\text{Arsenious dichlor-methide.}} + \underbrace{C_2H_3Cl}_{\text{Chloride of methyl.}}$$

The chlorine, bromine, and iodine compounds are neutral bodies of considerable stability; the two former are liquid, the latter solid and crystalline. By the action of chlorine or oxidising agents, they are transformed into bodies of the form $As\left\{\begin{matrix}R+\\R-\\R-\\R-\\R-\end{matrix}\right.$

Sub-type $As\left\{\begin{matrix}R+\\R-\\R-\\R-\\R-\end{matrix}\right.$ has only yet been explored in the methylic group. The oxygen compound constitutes anhydrous monomethylarsenic acid, a direct derivative from arsenious dioxymethide.

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\O\\O\end{matrix}\right.}_{\text{Arsenious dioxymethide.}} + 2AgO = \underbrace{As\left\{\begin{matrix}C_2H_3\\O\\O\\O\\O\end{matrix}\right.}_{\text{Monomethylarsenic acid.}} + 2Ag$$

This acid is bibasic, forming stable and well-defined crystallisable salts, the formulæ of which are represented by the general expression

$$As\left\{\begin{matrix}C_2H_3\\O\\O\\MO_2\\MO_2\end{matrix}\right.$$

The chlorine compound is exceedingly unstable; it may however be formed at 14° F., but is transformed at 32° into arsenious chloride and chloride of methyl.

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\Cl\\Cl\\Cl\\Cl\end{matrix}\right.}_{\text{Arsenic tetrachlormethide.}} = AsCl_3 + \underbrace{\left.\begin{matrix}C_2H_3\\Cl\end{matrix}\right\}}_{\text{Chloride of methyl.}}$$

Arsenic dioxydichlormethide is a somewhat more stable body formed by the direct union of chlorine with arsenious dioxymethide :

$$\underbrace{As\left\{\begin{matrix}C_2H_3\\O\\O\end{matrix}\right.}_{\text{Arsenious dioxymethide.}} + Cl_2 = \underbrace{As\left\{\begin{matrix}C_2H_3\\O\\O\\Cl\\Cl\end{matrix}\right.}_{\text{Arsenic dioxydichlormethide.}}$$

Nevertheless even this compound readily decomposes with the evolution of chloride of methyl.

In sub-type $As\left\{\begin{matrix}R+\\R+\\R-\\R-\\R-\end{matrix}\right.$ the oxygen compounds are feeble monobasic acids, of which cacodylic acid may be regarded as the representative. They are derived from the bodies $As\left\{\begin{matrix}R+\\R+\\O\end{matrix}\right.$ by direct oxidation, as already described. Cacodylic acid is remarkable for its stability, neither fuming nitric acid nor a mixture of sulphuric and chromic acids attack it even at the boiling point, and it may be heated to 390° F. without alteration. Although it is soluble in water, and contains upwards of 54 per cent. of arsenic, yet it is not in the least poisonous. Several deoxidising agents reduce cacodylic acid to the arsenious, or even to the diatomic, form. Thus phosphorous acid transforms it into cacodyl :

$$\underbrace{2(As(C_2H_3)_2O_3)}_{\text{Cacodylic acid.}} + 3(PO_3) = \underbrace{2As(C_2H_3)_2}_{\text{Cacodyl.}} + 3PO_5$$

Zinc also produces the same result.

The cacodylates have the formula

$$As(C_2H_3)_2O_3, MO.$$

Sulphocacodylic acid has not yet been isolated, but its salts present the same relation to those of cacodylic acid as salts of sulphur acids generally bear to those of oxyacids. Their formula is

$$As(C_2H_3)_2S_3, MS.$$

Sub-type $As\left\{\begin{matrix}R+\\R+\\R+\\R-\\R-\end{matrix}\right.$ has hitherto been very little explored: so far as it is known, however, its members bear so close a resemblance to their analogues in the antimony series as to require no further notice.

Tellurium Series. The close relations of tellurium to sulphur and selenium place the organometallic bodies of this series in the same position with regard to the sulphides and selenides of the alcohol radicals, as the antimony and arsenic series stand in relation to the corresponding compounds of phosphorus and nitrogen.

The following are the chief known compounds:

Tellurium-methyl	$Te_2\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.$
Tellurous dimethoxide	$Te_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\O\\O\end{matrix}\right.$
Tellurous methoxychloride	$Te_2\left\{\begin{matrix}C_2H_3\\C_2H_3\\O\\Cl\end{matrix}\right.$
Telluriumethyl	$Te_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.$
Tellurous diethoxide	$Te_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\O\\O\end{matrix}\right.$
Tellurous diethochloride	$Te_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\Cl\\Cl\end{matrix}\right.$
Telluriumamyl	$Te_2\left\{\begin{matrix}C_{10}H_{11}\\C_{10}H_{11}\end{matrix}\right.$?

The compounds of the alcohol radicals with tellurium are volatile liquids of most unbearable odour. They readily oxidise in contact with air, forming the respective oxides. Telluriumamyl has not yet been obtained in a state of purity.

The oxides of these bodies are powerful bases, expelling ammonia from its salts and attracting carbonic acid from the air. They form salts of considerable stability, which, together with the oxides themselves, yield the original organo-tellurium compounds when treated with sulphurous acid; thus,

$$\underbrace{Te_2\left\{\begin{matrix}C_4H_5\\C_4H_5\\O\\O\end{matrix}\right.}_{\text{Tellurous ethoxide.}} + S_2O_4 = \underbrace{Te_2\left\{\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Telluriumethyl.}} + S_2O_6$$

Constitution of Organometallic Bodies.

The organometallic bodies are supposed to be constructed upon the types of the inorganic chlorides, sulphides, oxides, &c., of the respective metals which they contain, the chlorine, oxygen, sulphur, &c., being replaced in equivalent proportion, and step by step by the alcohol radicals. A reference to the formulæ of organo-potassium, sodium, magnesium, zinc, and cadmium compounds given above, shows that they are all formed upon the models of the protochlorides of these metals:

$$M_2\left\{\begin{matrix}Cl\\Cl\end{matrix}\right.$$

The organo-aluminium compounds are formed upon the model of the sesquichloride of that metal:

$$Al_2\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right.$$

Organo-tin compounds are in like manner represented by the three chlorides of tin;

$$Sn_2\left\{\begin{matrix}Cl\\Cl\end{matrix}\right. \qquad Sn_2\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right. \qquad Sn_2\left\{\begin{matrix}Cl\\Cl\\Cl\\Cl\end{matrix}\right.$$

The bismuth series are modelled upon the terchloride of bismuth and bismuthic acid:

$$Bi\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right. \qquad Bi\left\{\begin{matrix}O\\O\\O\\O\\O\end{matrix}\right.$$

The lead compounds are constructed upon two of the oxides of this metal:

$$Pb_2\left\{\begin{matrix}O\\O\\O\end{matrix}\right. \qquad Pb_2\left\{\begin{matrix}O\\O\\O\\O\end{matrix}\right.$$

The mercury series have for their mould the bichloride of mercury:

$$Hg\left\{\begin{matrix}Cl\\Cl\end{matrix}\right.$$

The antimony series are formed upon the following inorganic compounds of that metal.

$$Sb\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right. \qquad Sb\left\{\begin{matrix}Cl\\Cl\\Cl\\Cl\\Cl\end{matrix}\right.$$

In like manner organo-arsenical compounds are constructed after the following types:

$$As\left\{\begin{matrix}S\\S\end{matrix}\right. \qquad As\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right. \qquad As\left\{\begin{matrix}O\\O\\O\\O\\O\end{matrix}\right.$$

Finally, organic compounds containing tellurium are derived from

$$Te_2\left\{\begin{matrix}Cl\\Cl\end{matrix}\right. \qquad Te_2\left\{\begin{matrix}O\\O\\O\\O\end{matrix}\right.$$

Occasionally an abnormal compound has made its appearance, such as ethostibylic acid ($Sb(C_4H_5)O_3$), or iodide of triethylstibine ($Sb(C_4H_5)_3I$), but further research has invariably demonstrated the incorrectness of such formulæ and the conformity of the bodies with the normal inorganic types. Indeed this law may now be regarded as so firmly established, as to be applicable to the control of the formulæ of new organometallic bodies. From this point of view it is interesting to watch the effect of the substitution of chlorous or negative by basylous or positive radicals in metallic compounds. Such a substitution affords striking evidence of the dependence of the chemical character of a compound upon that of its individual constituents; a phenomenon which is strikingly seen in the case of highly polyatomic metals, such as arsenic and antimony. Thus tribasic arsenic acid, by the substitution of an equivalent of methyl for oxygen, yields the bibasic monomethyl-arsenic acid, a well defined acid of considerable energy, though inferior in chlorous power to arsenic acid. The like substitution of a second equivalent of methyl for oxygen reduces the chlorous character of the body to the comparatively feeble condition in which we find it in cacodylic acid, which is incapable of forming an ammonia salt. A similar substitution for the third time overpowers the chlorous character of the compound altogether, and we now have a feeble biacid base—the arsenic dioxymethide; which again, by the exchange of a fourth atom of oxygen for methyl, is transformed into the oxide of tetramethylarsonium, a base of such energy as to be comparable with the caustic alkalies themselves.

The history of the organometallic bodies teaches forcibly a doctrine which affects all chemical compounds, and which may be called the doctrine of *atomic saturation*; each element is capable of combining with a certain limited number of atoms, and this number can never be exceeded, although the energy of its affinities may have been increased by combination up to this point. Thus zinc attains its atomic saturation by uniting with only one atom of another body, in other words, it is uniatomic; consequently, the zinc compounds of the alcohol radicals, notwithstanding their intense affinities, are incapable of combination. The action of chlorous elements upon them is one of substitution, not of combination. Polyatomic metals exhibit the same phenomenon: a double atom of tin cannot combine with more than 4 atoms; a single atom of arsenic or antimony with more than 5 atoms of other bodies. But in the combinations of polyatomic metals, we frequently notice from the lowest to the saturated compound one or more intermediate points of exalted stability; thus, antimony has a teratomic stage of comparative stability; nitrogen, phosphorus, and arsenic, whilst exhibiting a similar teratomic stage, have also a biatomic one, though of greatly inferior stability; whilst the existence of protoxide of nitrogen, and especially the recent researches of Mr. Griess render it more than probable that nitrogen has a third and uniatomic stage. In bodies possessing at least one stage of stability below saturation, and in which all the atoms united with the polyatomic element are of the same kind, the stage of maximum stability is very rarely that of saturation. Thus in nitrogen, arsenic, and bismuth compounds of the kind just mentioned, the stage of maximum stability is decidedly the teratomic one; in antimonial compounds of a similar nature, the teratomic is also, though less decidedly, the stage of maximum stability; whilst in phosphorous compounds, the points of maximum stability and saturation generally coincide. When, however, the atoms united with the polyatomic element are not of the same kind, then the stage of maximum stability usually coincides with that of saturation. Thus the binoxide or bichloride of triethylarsine, or triethylstibine, are more stable than triethylarsine or triethylstibine themselves; but this pentatomic stability reaches its climax in arsonium, stibonium, and phosphonium compounds, as it does also in the corresponding compounds of nitrogen, although the latter element exhibits a much stronger tendency towards universal teratomic stability than its chemical associates.

In polyatomic organometallic bodies it is remarkable that, with few exceptions, the positive hydrocarbons hold their position much more tenaciously than the associated negative constituents; and we thus frequently find the former accompanying the metal through a vast number of compounds; hence the group formed by the metal and positive hydrocarbons has come to be regarded as a compound radical: thus cacodyl is conceived to be the radical of the whole series of cacodyl compounds: but however great may be the convenience of this mode of viewing organometallic compounds, and the same mode has notoriously been extended to nearly all organic bodies, it must not be forgotten that it is a purely artificial distinction which has no real existence, either in the case of organometallic bodies, or in that of organic bodies in general. A close examination of the habits of the so-called organometallic radicals clearly shows that their atomic power depends upon their position with regard to the stages of stability and maximum saturation; thus they are uniatomic when the number of positive groups is one less than that required to reach either the maximum saturation of the metal, or a lower stage of stability. Cacodyl and tetramethylarsonium, for instance, are uniatomic radicals, because they are respectively one atom short of the stage of stability and of maximum saturation:—

Uniatomic stage.	Stage of stability.	Uniatomic stage.	Stage of maximum saturation.
$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\end{matrix}\right.}_{\text{Cacodyl.}}$	$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\Cl\end{matrix}\right.}_{\text{Chloride of cacodyl.}}$	$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\end{matrix}\right.}_{\text{Tetramethylarsonium.}}$	$\underbrace{As\left\{\begin{matrix}C_2H_3\\C_2H_3\\C_2H_3\\C_2H_3\\Cl\end{matrix}\right.}_{\text{Chloride of tetramethylarsonium.}}$

It is obvious, that under favourable circumstances, a compound radical, the number of whose positive atoms is below that of a stage of stability, can have a double atomic character. Thus cacodyl is sometimes uniatomic, as in oxide of cacodyl, and sometimes teratomic, as in cacodylic acid ($As(C_2H_3)O_2$). Again, arseniomonomethyl (AsC_2H_3) is biatomic in arsenious dioxymethide and quadratomic in monomethylarsenic acid.

ORGANON. [In the article Logic we have explained our reasons for allowing this article, from the pen of the editor of the 'Penny Cyclopædia,' to remain without any attempt to bring it into connection with the new matter of the present work. To it is added the article from the first Supplement to the 'Penny Cyclopædia.']

It is not possible to give a definition of any science which shall convey its full import, and particularly to a person who does not already know what it is. This difficulty will be experienced by any one who attempts to give a definition of Logic. Without then attempting a definition, or admitting the completeness or correctness of any definition hitherto given, it may be sufficient, for the purpose of showing what that matter is about which we are discoursing, to say that logic is conversant about the formal laws of thought, and that it is not conversant about the matter which is subjected to such laws.

This thing, whatever it may be, about which logic is conversant, is presented to us, and is considered by us generally under the form of language. Whatever are the operations of the mind which are involved or contained in the exercise of thought, those operations may be generally expressed by language. It is assumed here, that by whatever names we designate the relation of the various consecutive and connected trains of ideas which pass through the mind, this relation is in all minds essentially the same. When two persons then possess a common language, one of them can express in this language, with a certain degree of accuracy, the various consecutive and connected trains of ideas which have passed through his mind, with respect to any matter or matters. Another person, who, to use the common expression, understands this language, can, through this medium, communicate with the other person's mind; and if the expression of such ideas has been accurately made according to the form of the language, and if they are properly interpreted, the person who hears or reads what the other has written or said, may in his own mind perceive the same various consecutive and connected trains of ideas which the writer or speaker has experienced. If language can effect this, it follows that the mental operations or processes in the two individuals are connected and assimilated by virtue of their both being conformable to the same general laws. It is, however, the laws of thought about which logic is conversant, and with language no further than as being the form of expression in which the thoughts of others are made known to us, and by which we are enabled to compare those thoughts with our own.

Under the article Language it has been stated in a general way what language is; but mainly as to the materials of which it is composed. It remains now to consider its form.

What is called a sentence comprehends in its simplest form a subject and a predicate, with something by which a relation between the subject and the predicate is expressed. "Men die" is a sentence, in which "men" is the subject, of which "dying" or "death" is predicated, that is, in this sentence a judgment is expressed. The sentence indicates that two notions are present to the mind, "men" and "death." What the relation is which the mind really contemplates between these two things, and how it is possible for the mind to contemplate this or any other relation between two things, belongs not to the present inquiry, nor to the province of logic. It will be sufficient to observe, that this judgment or relation does not express or mean, as some writers say, any *agreement* or *disagreement* between the two notions, or that one of them belongs or does not belong to the other; nor is it the *comparison* in the mind of these two notions, at least, logically considered, it is not the comparison in the mind of the two notions as to the matter of them.

The sentence "men die" may also be expressed thus,—"men are mortal;" where mortal is the predicate. The grammatical relation between "men" and "mortal," which is the symbolic representation of that conceived by the mind, is expressed in our language by the substantive verb "are," which is accordingly, in such sentences as this, called the copula. In some languages, as the Latin and Greek, which are rich in terminations, the relation between "men" and "mortal" is also expressed by a termination attached to the word "mortal," in addition to the copula, as "homines sunt mortales;" and sometimes the copula *est* is omitted. When there is not a copula, either in the form of the verb "to be" or in some other verb of equivalent meaning, the copula is either expressed solely by the order of the words, which is the case with those languages which, like the English, have few terminations, or the copula is expressed by a verbal termination which has a certain relation of fitness to the nominal termination, as in Latin and Greek, and in some cases by the order of the words also, as "homines moriuntur." The copula in itself has no meaning; its office is to indicate that the subject and the predicate of the sentence are contemplated at once, and each in some relation to the other, in that operation of the mind of which the words "men are mortal" is the visible or sensuous sign. But the subject itself may be qualified by an attribute, or the generality of the subject (which according to the common interpretation of language is understood when it is not limited) may be restricted or confined by the use of appropriate words, as, "dying men are prophetic," or "some dying men are prophetic." Again, the predicate may in like manner be qualified or limited; as, "he writes," "he writes a letter," "he writes letters sometimes." Thus every sentence, however complicated it may appear, is reducible to the form of subject, predicate, and copula. "A tall man on horseback in complete armour was seen crossing a deep and rapid river on a winter's day," and other sentences of the kind with which ordinary books of narrative abound, may all be reduced to a simple form. It is true that the number of different things or notions which such a sentence brings before the mind often create a degree of confusion, and render the apprehension of the affirmation or negation, which every simple sentence contains, a matter of some difficulty; and this is particularly the case when a sentence so constructed brings before the mind not material objects with which we are familiar, but notions which express things which are not subject to the cognisance of the senses. And hence it happens that argumentative discourse is not always the most difficult to apprehend. Indeed the difficulty of apprehension is sometimes greatest when the discourse consists of a long series of propositions in which under one set of circumstances one thing is affirmed or denied, or commanded or forbidden; and under another set of circumstances other things are affirmed or denied, or commanded or forbidden; or when things are stated, affirmatively or negatively, with a great many exceptions and limitations. A perusal of a modern act of parliament will show that this is so.

Sometimes there may appear to be, and in fact may be, a difficulty even in a very similar sentence, as to the resolution of it into subject, predicate, and copula. The discussion of this matter belongs to the doctrine of propositions; but so much may be here said, that so far as all propositions are contemplated in their formal and not their material character, they agree in this, that the subject is viewed as something either co-extensive with or included in the predicate. Both the form of language and the form of thought of which language is merely the exponent, forbid us to contemplate a subject in a greater extent than its predicate. The sentence "I hope to succeed" is thus reduced (Whately's 'Logic,' p. 59):—

$$\overbrace{\text{To succeed}}^{\text{sub.}} \qquad \text{is} \qquad \overbrace{\text{what I hope}}^{\text{pred.}};$$

which is the same thing as "success is my hope;" and the remark is made "that an infinitive (which the author has already defined to be a noun substantive) is never the predicate, except when another infinitive is the subject." But we may just as well express the proposition thus:—

$$\overbrace{\text{What I hope}}^{\text{sub.}} \qquad \text{is} \qquad \overbrace{\text{to succeed}}^{\text{pred.}};$$

that is "my hope is success." Now as both "hope" and "success" are general terms, that is, are words capable of being applied severally to an infinity of particular things; and as neither hope nor success are conceived by the mind in any relation of subordination to one another, as that either of containing or contained, or of species and genus [Genus], it is indifferent whether we use the phrase *my hope* (sub.) is *success* (pred.), or success (sub.) is my hope (pred.). But this sentence, we conceive, would by most people be reduced thus:—

$$\overset{\text{sub.}}{\text{I}} \qquad \overbrace{\text{hope to succeed}}^{\text{pred.}};$$

where "hope of success" is that which the subject, ego, predicates of itself, that is, these words indicate a mental operation in which the subject (it matters not whether contemplating itself or contemplated by another) is viewed (logically) simply as *within* certain limits of predication.

Every simple sentence which is intelligible is reducible to the form A is or is not B; but it should be observed that the former sentence has two meanings, as already observed. It may mean either that A is contained in B, or that A is coextensive with B, where A is the subject, and B the predicate, and *is* the copula. It is important to bear in mind this double meaning of the sentence "A is B." If it should be said that "A is B" may also mean "A contains B," we can then say that B is contained in A; and so we are where we were before. In ordinary language the ambiguity of the form A is B is sometimes removed by words of limitation, as "all," "every," "some;" but frequently there are no such words used, and the consequence is ambiguity.

The sentence "A is not B" may mean either that A is not co-extensive with B, or that no part of A is contained in B, or that some part of A is not contained in B; but this ambiguity also is generally avoided in common speech by the use of words of limitation, or by attaching the negative to the subject. It is obvious that negative propositions are subject to more ambiguity than affirmative propositions. Negative propositions have given logicians much trouble, and it is clear that we only obtain a clear notion of their import by a tacit reference to affirmative propositions. In itself a negative proposition has no meaning; by the very supposition of its being negative, it excludes the notion of all significancy; and yet by means of such propositions we attain to knowledge. The Stoics (who seem to have had a logic of their own) called such a sentence as "Pleasure is not good" an affirmative sentence also: their reasons for this are stated, though somewhat obscurely, by Apuleius. ('Philosophy of Plato,' lib. iii.)

Simple sentences are generally combined in written or spoken discourse in such a manner that the whole meaning of the speaker cannot be reached, except by considering two or more sentences together. Sentences may be so combined, either in the way of co-ordination or sub-ordination, but this distinction, which is made by Dr. Becker in his excellent German grammar, though it is applicable to some extent to all languages, is perhaps more particularly applicable to the German language than to our own. Two sentences are combined by way of co-ordination when they are connected by such a conjunction as *and*, as "he eats and drinks," where we have two distinct sentences, each of which contains a separate and independent affirmation; but we cannot reach the whole of what is said of the subject "he," without contemplating the two sentences together. The conjunction "but" is also often used to unite co-ordinate sentences, as "he speaks German, but not fluently," where the sentence beginning with "but" limits the generality of the former assertion; and the whole sentence does not differ in meaning from "he speaks German, and he speaks German not fluently." Subordinate sentences are connected with the principal sentence in a great variety of ways, among which the union by means of the pronouns and words of pronominal origin is perhaps the most frequent: as, "I do not know when he will come;" "he lives luxuriously, while others are starving."

In both cases, both the combination of co-ordinate sentences and the combination of subordinate with a principal sentence, certain words are used, which are generally distinguished from other words which connect sentences, by the name of *causal*; such are in English, "for," "therefore," "then," and "since" (not as words indicating time), "because," and some others. All languages have words which correspond in meaning to these words. Now it is the combination of sentences produced by such words as these which generally makes up a large part of discourse, written or spoken. When the discourse is bare narration of facts, it is often little more than a succession of affirmative or negative propositions, but so connected and expressed as to render the discourse more pleasing than if the propositions were enunciated separately and in their simple form; but still not logically connected. Besides the ornament and variety which we are enabled to give by written discourse to mere narrative, there is generally a kind of coherence or sequence in the bare facts of narration, which, when some facts are known, can be anticipated by the hearer, or reader, and this again helps to render the language of bare narration less tedious.

But when discourse is not limited to bare narration of facts, it assumes a form which still more interests the hearer or reader, and keeps his intellectual powers in constant exercise. Here the discourse does not barely communicate something from the writer to the reader: it does more; it is constantly addressing itself to those faculties of the reason which the reader and the writer have in common, and it is constantly proceeding on the assumption that a great number of universal propositions are admitted to be true by the reader and the writer. Thus, if we say of a certain man—"he is not liked, because he is presumptuous," two things are affirmed; first, that a "certain man is not liked;" second, "that he is presumptuous." But by the use of the word "because," the writer means to affirm something more than the truth of the two propositions; for we may suppose it possible to affirm many propositions of a man without considering the propositions related to one another in any other way than as all relating to one man as the subject. The words "because he is presumptuous" are designed by the writer to express some connection with or relation to "not being liked," which connection or relation must exist in the mind of all other persons as well as in his own, or it cannot be understood. Now, what is that connection which he and all mankind, and a large part of mankind unconsciously, contemplate when this compound sentence is enunciated? The subject of the whole sentence is some given person or individual who is said "not to be liked," a proposition universally intelligible. He is said "to be presumptuous," which is also universally intelligible. Now, the word "because" has this office:—it introduces something to the reader's notice to which the universal judgment of mankind attaches the notion of dislike; something which is followed by dislike; something without which there may be dislike, but with which there must be dislike; that is, *must be* in this sense: the reader does not know the individual spoken of, and therefore does not know that he is disliked till he is told so; but he knows something of that individual, namely, his presumption, and he also knows that he dislikes a presumptuous individual. He therefore understands the writer, and he admits that statement which is introduced by the word "because" as a *reason* (to use the common expression) why the man is disliked. He has in fact assented to the universal proposition that "a presumptuous man is disliked;" he has already mentally formed for himself a general rule that all presumptuous people are disliked, and it is by virtue of himself and the writer acknowledging this universal affirmation as true, that he collects the writer's meaning. But there is no logical inference here; there is no syllogism.

The speaker or writer might, however, say, all that he know of a certain man was "that he was presumptuous;" and he might add to the sentence, and "therefore I conclude that he is disliked." If the reader or hearer assented to the conclusion introduced by the word "therefore," he would assent to the following mode of stating what he had heard:—

1. All presumptuous persons are disliked.
2. This man is a presumptuous person;
3. Therefore he is disliked;

which is called a syllogism, and is one of the most common forms of a syllogism, in which the first part, or major premiss, is not expressed. The greatest part of written and spoken discourse is either in this form or in that of a consecutive series of syllogisms, called, by logicians, sorites.

The first two propositions are generally called the *premises*, and the third is called the conclusion; and in such a syllogism everything which is called a conclusion is deduced, or considered as deduced, from two other propositions, one of which, as already observed, is commonly suppressed, but is referred to by such a word as "because," "therefore," &c. It is, however, very clear that nothing is *proved* even by a syllogism. In the common form of language something is affirmed particularly as a fact, and something is said in the way of a conclusion. The mind perceives no reason why this conclusion is made in the particular instance, more than it should be in any other given instance of the same kind. But while something is in form concluded particularly, something is by implication affirmed universally. A person not accustomed to analyse his own thoughts may not always be able to discover what is that universal affirmation which contains the particular conclusion; but if the argument, as it is generally termed, be expressed in the complete form of a syllogism, he at once perceives what universal proposition must be admitted or proved, in order that the particular one shall be true; if he has already given his assent to the proposition as stated, without a clear conception of the extent of the admission which he will be considered to have made, he is enabled by means of the syllogistic form to examine more clearly that mental operation which to him was before confused. The conclusion of the syllogism *proves* nothing; as an inference or illation it necessarily follows from the premises, that is, the mind cannot conceive it otherwise; and in this operation it is subjected to laws of thought which are irresistible. When the truth of the premises is ascertained or admitted (which, for the purpose of argumentation, is the same thing) the conclusion, which before was logically correct, now becomes also true. All discourse of the kind called argumentative, indeed all discourse so far as it contains inferences, may be reduced to the form of a series of syllogisms, from which it will appear what universal affirmations or negations are implicitly contained in the discourse. It will also show what universal affirmations or negations are used as a means of attaining to other affirmations or negations which are not true unless the first are true, and which when attained become the premises of other conclusions. Discourse of the argumentative kind has for its object to establish particular things, or things which are comprehended within other things. Particular things, so far as they are the object of sensuous perceptions, are directly established by evidence, as for instance, the qualities of any material object; but there are many things which are not susceptible of this kind of evidence, and of which there is no evidence but the universal consent of mankind. In an argumentative discourse therefore the writer who has particular things to prove, alleges, expressly or by implication, universal truths, and he affirms, either expressly or by the implication of language, that the particular things are contained within the universal. If the reader assent to the universal truths, and also admit that the particular things are contained therein, the writer accomplishes his purpose, and his demonstration is complete. He is said to have deduced something, or to have made a deduction. If all written or spoken discourse were in the form of perfect syllogisms, there could be little confusion or dispute about what is called the premises and the conclusion, for the whole matter would be so placed before the reader, that he would always perceive the general proposition within which it is affirmed that the particular is included. It is then the general condition of every syllogism imperfectly expressed, that when we are speaking of what we call one thing, we are in effect speaking of many things: for that which is asserted of one can equally be asserted of all things of the kind, and it is not possible to conceive it true of one without conceiving it true of all.

Some writers have observed that the causal conjunctions are employed to denote respectively cause and effect, as well as premiss and conclusion; as in the following examples:—"This ground is rich *because* the trees on it are flourishing;" or, "the trees are flourishing, and *therefore* the soil *must* be rich;" where the conjunctions *because* and *therefore* are considered to be used to denote the connection of premiss and conclusion. But in the following sentences, "the trees flourish *because* the ground is rich;" or "the ground is rich, and *therefore* the trees flourish;" the same conjunctions, it is said, are used to denote the connection of cause and effect; and it is added that in the latter case "the luxuriance of the trees, being evident to the eye, would hardly need to be *proved*, but might need to be accounted for;" and as to the former case, it is remarked, "that the luxuriance of the trees is not the cause of the soil's fertility, but only the cause of *my knowing it*."

Now in the expression, "the trees are flourishing, and *therefore* the soil *must be* rich" (if for *must be* we write *is*, which ought to be done), it may be meant to affirm, either that the trees are flourishing, and that the quality of the soil is unknown; or it may be meant that the trees are flourishing, and that the soil also is rich. In the former case the richness of the soil is concluded, according to the common expression, from the suppressed premiss of the invariable coincidence of flourishing trees and rich soil, and as the world knows or says (which for the present purpose is the same thing) that a rich soil is necessary in order that trees may flourish, the richness of the soil is in fact, according to the common notion of cause and effect, here also considered to be the cause of the luxuriance of the trees, if we look to the matter of the syllogism. In the latter case, if both things are affirmed, both that the trees flourish and that the soil is rich, the same thing is affirmed as in the sentence, "the ground is rich and *therefore* the trees flourish;" and in both these cases, when the two propositions are considered as affirmations, not connected in the way of conclusion, nothing more is effected by the word *therefore* than to suggest the notion of the invariable coincidence of flourishing trees and rich soil.

The Conclusion of the "ground being rich *because* the trees on it are flourishing" (the richness of the ground in question not being known otherwise than by the trees) cannot be made except from the premiss, "wherever trees flourish, there the ground is rich." Now though it may be true that "wherever trees flourish, there the ground is rich," it may not be true that "wherever the ground is rich, there trees flourish," for the ground may be rich, and covered with water in which trees will not flourish. But if we affirm that "the trees flourish *because* the ground is rich," we affirm both "that the trees flourish" and "that the ground is rich," which again is nothing more than affirming by implication that "wherever trees flourish, there the ground is rich," leaving it, as before, possible that there may be rich ground where trees do not (for some reason or other) flourish.

Now it is said that in the former case, where a Conclusion is made, the luxuriance of the trees is considered to be the cause of *my knowing* the fertility of the soil; that is, in the conclusion, "the ground is rich because the trees on it are flourishing;" "the ground is rich" is my (concluded) knowledge, and *because* is there used to express cause and effect, as between "flourishing trees" and "my knowledge." In the latter case, where both propositions are affirmative, but neither of them in the way of conclusion, it is said that the luxuriance of the trees does not require *proof*, but requires to be accounted for; that is, richness of soil and luxuriance are here considered in the relation of cause and effect. According to this, *a* relation of cause and effect, though not of the same cause and effect, is indicated in both cases by the word *because:* and in the former case the richness of the soil is considered to be *proved* also.

This is rather perplexing, but perhaps the perplexity may be got rid of thus:—"The ground is rich *because* the trees on it are flourishing," is necessarily true, if it is also true that "wherever trees flourish, there the ground is rich;" but this general proposition must be *proved* in some way or assumed, in order that the logical conclusion may also be a true conclusion. "The trees flourish, *because* the ground is rich:" here both facts are *proved* or assumed (which for the present purpose is the same thing), and it is also affirmed by implication that "wherever trees flourish, there the ground is rich." The difference between the two sentences then is this:—the former affirms that a particular soil is rich, if soil is always rich under similar circumstances; and the reduction of the expression to the complete syllogistic form shows us what must be proved or assumed in order that the conclusion shall be true in this particular case. The latter affirms the particular thing to be true, which in the former is only true upon a certain condition; and it also affirms by implication the truth of this certain condition. The former is a syllogism, because that which is said of the whole may be said of a part. The latter is nothing more than the implicit statement of a general proposition contained in the explicit statement of a particular instance: it is no logical inference; it is no logical induction; it is simply a statement of a thing being true in a certain case, with an implicit assertion that the same thing is true in all similar cases; in other words, the form of language implicitly contains the affirmation of a general proposition, which can only be the result of an induction in the non-logical sense of that term.

The difference between logical Deduction and Induction is explained in the article INDUCTION. But it will not be out of place to say a few words on the subject here. In the Deductive Syllogism, we proceed from the whole to its parts, from the thing containing to the things or some of the things contained; and this is true notwithstanding it is not so expressed in the common form of language. For the particular conclusion, as already observed, is the thing which in ordinary language is said to be proved; but there is no demonstrative evidence to the mind, except it is shown that the particular conclusion is contained in a general proposition. The deductive syllogism as already explained shows what this general proposition is, and this general proposition is assumed to be true, or is known to be true in some other way (by induction, properly so called, for instance) than by means of the syllogism. But there is another mode of operation by which the mind can proceed from particulars to generals; but this, which may be called the Inductive Syllogism, is no syllogism, that is, no necessary conclusion, unless *all* the particulars are enumerated, or assumed to be enumerated; and in this consists the difference between the Inductive Syllogism and Induction, or what is sometimes, but, we think, not with strict propriety, called Inductive Reasoning, which however is no operation of reason, but one of the understanding only; or, to prevent disputes about terms, it is not the same mental process as that of the Logical Induction, for its conclusion is not necessary. This Induction then, which leads us from the observation of one or more like facts to make a general assertion which will comprehend like facts not observed, is a material illation of quite a different character from the other. This process has sometimes been absurdly considered as a peculiar discovery of modern times, though it must have been practised by the first man who ever made use of his eyes. The process of investigating and collecting facts which are among the phenomena of the material world, has been greatly *improved* in modern times.

That syllogistic form which is properly called Inductive (ἐπαγωγή) is explained, though very briefly, by Aristotle (*Analyt. Prior.*, ii. 23; *Topic.*, i. 12), and is not confounded by him with the material induction of a general law or rule from the examination of a number of particular cases of a like kind.*

If we wish to prove syllogistically the mortality of a given individual John, we say—

All men are mortal;
John is a man;
Therefore John is mortal.

Now this conclusion is necessary, because "John" is contained in "all men." But suppose we wish to prove our primary proposition, that "all men are mortal," what is the process that we must follow? We may affirm mortality of all men who have died, but we cannot affirm it of all who are living and who shall live, for that is the thing to be proved. This is a case in which there can be no logical, that is, no necessary conclusion.

Dr. Whately says (p. 229) "that in the process of reasoning by which we deduce from our observation of certain known cases an inference with respect to unknown ones, we are employing a syllogism in *Barbara* with the major premiss suppressed; that being always substantially the same, as it asserts 'that whatever belongs to the individual or individuals we have examined, belongs to the whole class under which they come.'"

And he further says that induction, "so far forth as it is an *argument* (which has previously, in the same work (p. 55), been defined to be a 'syllogism when regularly expressed'), may of course be stated syllogistically; but so far forth as it is a *process of inquiry* to obtain the premises of that argument, it is of course out of the province of logic" But a syllogism will be equally good (p. 14) if we substitute arbitrary symbols for the terms, without any regard to the things signified by them; and (p. 23) "every conclusion is deduced from two other propositions or premises." This so-called induction then, stated syllogistically, turns out to be nothing different from a proper syllogism: if the premises are true, the conclusion is necessarily true. The syllogism then has done nothing, and it leaves the process of inquiry precisely where it was before the induction was put into this so-called syllogistic form.

This mistake requires a few more words, as it has been declared to be "a just, and, so far as we are aware, an original remark; and its consequences are extremely important." (*Westminster Review*, No. 17, p. 169).

The deducing an inference from facts investigated and collected is said to be an argumentative process, and like other arguments (that is, syllogisms), capable of being syllogistically expressed. If it is a syllogistic process, it is undoubtedly susceptible of the strict syllogistic form. Now this so-called inference is the making a universal affirmation founded on a number of particulars; and if it is a syllogism, the universal affirmation is the conclusion; and if it is a syllogism, the conclusion is necessary. The conclusion is by the supposition a conclusion from certain known things as to other unknown things; and the universal conclusion is, that something is true of the unknown things which is known to be true of the known ones; in other words, that this something is true both of the known and the unknown things. Now in order to attain this syllogistic conclusion, it is said that we employ a syllogism, in which the major premiss is of this form: everything which is true of the known is true of the unknown, or everything which is true of the known is true of the known and the unknown.

To take Dr. Whately's own example:—"from an examination of the history of several tyrannies, and finding that each of them was of short duration, we conclude that the same is *likely* to be the case with all tyrannies." And it is said that in such syllogisms as these, we assume "that *whatever* belongs to the individual or individuals that we are examining belongs to the class under which they come." Now this universal affirmation is a proposition *to be proved* in some way or other. If it be assumed, it is the major of a deductive syllogism, and the conclusion is logically necessary, and also true, if the major is true.

---

* Ἐπαγωγὴ μὲν οὖν ἐστιν, καὶ ὁ ἐξ ἐπαγωγῆς συλλογισμὸς, τὸ διὰ τοῦ ἑτέρου θάτερον ἄκρον τῷ μέσῳ συλλογίσασθαι.

But how is this major to be established, by virtue of which we are to have a logical illation and a true conclusion? It is admitted that in induction, properly so-called, a general material truth is to be affirmed by virtue of *particular* facts being investigated and known. But if we affirm some proposition which is more general than and comprehends that which we wish to establish, and then so construct our syllogism that the conclusion shall be a logical inference, it cannot be a true one unless we establish this more general premiss. But the object of the true induction is to establish the general truth from particular facts that are known and investigated. If, in the case supposed, the syllogism is valid, the particular facts are useless; the conclusion is logically good, and it becomes materially true when the more general proposition is established which contains the conclusion. But it is not the object of the investigation and collection of facts to establish a proposition different from and more general than that for the establishment of which the facts are investigated and collected; in other words, it is not the matter in hand to investigate and collect facts for a particular purpose, and then not to use them for that purpose.

In this so-called syllogism then we have a suppressed major of this form, "that which is true of some is true of all," which must mean either "everything which is true of some is true of all," or, "this one thing which is true of some is true of all." In the former case, the suppressed major expresses a general proposition, which we must establish in order that our illation, which is logically correct, may be true materially; but then this is not the proposition which we profess to be desirous to establish, and, more than that, it cannot be established by the facts investigated and collected. If it means that this *onething* which is true of some is true of all, this is nothing more than to make the conclusion the major premiss, and so to conclude the conclusion from itself. It cannot be supposed that Dr. Whately has any such absurd meaning as this: but his language is capable of this meaning. He does however mean either this or the other; and it is not easy to say which is the less logical meaning of the two.

A few more words seem necessary on another passage in Dr. Whately's work, by way of clearing the way to a right comprehension of the province of logic. It has been already observed that discourse or speech generally assumes the form of a syllogism with one of the premises suppressed; which is by many modern logicians called an enthymeme.*

Dr. Whately observes that the enthymeme (the enthymeme of modern logicians) "is *not strictly syllogistic*, that is, its conclusiveness is not apparent from the mere form of the expression, without regard to the meaning of the terms; because it is from *that* we form our judgment as to the truth of the suppressed premiss. The expressed (qu. *suppressed*) premiss may be true, and yet the conclusion false." The reason here given why the (so-called) enthymeme is not strictly syllogistic is, that we form our judgment of the truth of the suppressed premiss from the meaning of the terms. This is a singular reason. The *truth* of the suppressed premiss has nothing to do with the validity of the conclusion as an inference. If the suppressed premiss were expressed, the question as to the conclusion would be, not whether the suppressed premiss were true but whether it necessitated the conclusion. If the conclusion is already made and one premiss only stated, the *truth* of the suppressed premiss is not the matter in question, but only *what* it is; and when we have ascertained what the premiss must be in order that the conclusion may be valid as an inference, we may then inquire if the suppressed premiss is true. The expressed premiss cannot be true and the conclusion false, for the proper suppressed premiss is virtually involved in the conclusion and the expressed premiss. Besides, the mere form of the expression does indicate the suppressed premiss; if it did not, the enthymeme, that is, the incomplete syllogism, the syllogism of common discourse, would be incapable of being expressed in the form of a complete syllogism. If we say A is C, *because* or *for* it is B, which is the mere *form* of the expression, we see that the suppressed premiss is, B is C, that is, B is contained in or is co-extensive with C; and every person who can comprehend the notion of a containing whole and its contained parts will understand what is meant if it is expressed in this form; A is contained in C because A is contained in B. As if a man had found that any one thing could be contained in another (second) thing, and this other (second) thing were contained in a third, he would conclude mentally that this one thing was contained in the third; and the form of his expression would be, it is contained in the third *because* it is contained in the second, in which he would tacitly suppose that the second is contained in the third, and would then necessarily conclude that the first is contained in the third.

We are now in a condition to show what are the limits of pure logic, or of a pure logic. All propositions and all syllogisms are the subject of a pure logic only so far as they have all something in common. They have only something in common so far as they are all capable of being reduced to a common form or forms; that is, a pure logic is formal only. Neither the syllogism nor its parts regard the matter, and the propositions which enter into the syllogism are only the object of logic so far as they are connected by *is* and *is not*. And since all propositions, when viewed solely as the parts of a syllogism, must be capable of being reduced to the same form or forms, it follows that all propositions as logical elements connected by *is* and *is not* are only viewed in that way in which the reason does, and must because it does, view all things which are so presented to the mind independently of the matter, namely, with relation to the notion of a containing whole and contained parts.

If this exposition seem tedious, the fault is with those who, while they profess to teach pure logic, confound it both with an applied logic and with other things also.

There seems to us another error in Dr. Whately, which is worth noticing: he says, "No conversion is employed for any logical purpose, unless it be illative;" and he adds, "the reader must not suppose from the use of the word 'illative,' that this conversion is a process of *reasoning*: it is in fact only stating the same judgment in another form." Now if we say A is B, meaning that A is contained in B, it is a logical consequence or conclusion, though not a syllogistic one, that B is not contained in A. In this case then there can be no unlimited logical conversion of the proposition. If A is co-extensive with B, then B is co-extensive with A; in which case there is a logical conversion. The laws of thought necessitate the non-conversion in the one case and the conversion in the other; and if these are not logical conclusions, there is no such thing as a pure logic or reasoning.

It is generally said that logic teaches us to reason correctly, or that it shows the process which takes place in the mind when a man does reason correctly. It is however difficult to admit the accuracy of this statement. If a man reasons at all, in the strict logical sense, he reasons correctly. Language is seldom expressed in the form of syllogisms, and it is not usual to express, in any way, both the propositions from which we deduce a conclusion. We generally express ourselves by way of a conclusion and one premiss. Now this being so, the suppressed premiss may always be discovered by somebody, though the speaker or writer may not always be able to discover his own suppressed premiss. The conclusion and one premiss being given, the suppressed premiss is also given, for the conclusion and the expressed premiss necessitate the proper suppressed premiss. They who say a man argues incorrectly, when he states a conclusion and one premiss only, *assume* that his suppressed premiss is not that suppressed premiss which the two data require, but some other. But if some other, it is impossible that they can find it out, and therefore they cannot confute him. It is only because the suppressed premiss (perhaps not known to the speaker) pointed to by the data, is the real one, that we can confute the speaker. We show what the suppressed premiss is, and then we are in a condition to dispute it, and to ask him for proof of it. A man then does reason correctly when he reasons by a conclusion and one expressed premiss. The syllogistic form shows what the premiss must be, that is, it leads to the full interpretation of the speaker's meaning. But suppose a man expresses all the terms of a syllogism, and his syllogism is vicious, is it vicious because he reasons wrong, or because he has given a meaning to some of his terms which other people do not, or has altogether mistaken them? We think that his reasoning, *as such*, is and must be correct. His apprehension may be and often is wrong. In this view, reasoning, *as reasoning*, is always correct reasoning. It has been objected to this by a friend, that many persons who are not familiar with logical considerations, on being asked whether, if every A is B, every B is also A, will admit this conversion to be true. It is then asked if, in admitting this, they reason correctly. The answer to this difficulty is furnished by the objector, who goes on to say, that if the person who admits this conversion is asked the same question as to a material conversion, such as, every goose is an animal, he immediately perceives that he cannot say every animal is a goose. This shows that his apprehension of the expression, every A is B, was incorrect, that is, he did not understand it, but took it to mean something different from what the person intended by it who put the question.

In argumentation the conclusions are the matters which are directly disputed; but the suppressed proposition is generally the real matter in dispute, or the meaning of a term is the matter in dispute. The use of logical forms consists in showing fully and explicitly what is expressed imperfectly and only implicitly in the common form of language; and its use is not a bit the less because it neither teaches to reason nor convicts our reason of error. Its use is to indicate to us all the formal elements and conditions of dependent truth. It points out to us and leads us to the consideration of the several propositions which discourse contains, and from the consideration of the several propositions it leads to the terms, and there it leaves us.

The cause of this confusion between logic and metaphysic is obvious, and lies in the necessity which all men feel of a metaphysic of some kind or other. General terms and general propositions, the elements of every material syllogism, are deeply fixed in the mind long before its consciousness is awakened to the cognisance of the operations of the reason; and in many minds this consciousness is never called into existence. Logicians clearly perceive the value of the syllogistic forms as an aid and a formal help in analysing the reasoning process in a given case: they also see or feel that the reasoning process in itself is not knowledge, but they see that it is a means to knowledge. Its barrenness in itself is confounded with its productive powers when exercised on a material, and hence they have come to confound its operating energies with its products; as if a man should confound his tools with that which is produced by his tools operating on his materials.

---

* It has been observed by Sir Wm. Hamilton ('Edinburgh Review,' No. 115) that this is not the meaning of the enthymeme of Aristotle, which is quite true; nor is it the meaning of the enthymeme of Cicero. The following passages may be referred to as showing the meaning of the old enthymeme (ἐνθύμημα), which seems to have been taken by different writers in different senses: Aristotle ('Analyt. Prior.,' ii. 27): Cicero, ('Topica,' 13, 14); Demetrius Phalereus (περὶ Ἑρμηνείας, s. 30). The enthymeme of Boethius is the modern enthymeme ('Comment. in Cic.' Topic., i. c. 2.)

A pure logic will lead all men to a metaphysic, for a pure logic has its use in its applications. A metaphysic, as a system, if it does not contain a logic, will lead to the results of most systems of metaphysic, that is, to none at all.

Thus it appears that the study of logic is perhaps the proper introduction to a metaphysic; and it were much to be wished that all who have written on the latter had first been subjected to the discipline of the former.

The forms of the SYLLOGISM are considered under that article, consistently with the plan of this work. In the mean time, till we have some system of logic in our language which is founded upon and grows out of some philosophical system, it is better for the student to study only a purely formal logic, which is independent of any philosophical system, and to apply it to his various studies.

The question, What is Logic? has been a matter of much dispute. It has been disputed whether logic is a science or an art, or both—an idle question, which may be safely left undecided. It is more important to determine what is comprehended in the term logic, and this has partly been attempted here. It is also of some importance to show that the notions of this science do not appear to have been very exact among the Greeks and Romans, which may be one cause of the traditional confusion as to the limits of logic, which has been so common in modern times. It may be also useful to show what logic is conceived to be by some modern writers.

There is no definition of logic in the extant works of Aristotle; and if we deduce from his Organon, as we now have it, our notion of what the term comprehends, we shall find that it contains a great deal which does not belong to logic as it has been understood by those who have formed the most exact notions of it. If we should attempt to ascertain what logic is from the writings of all who have written on logic, it will be found impossible to form any exact notion of its limits and objects.

Dialectic is distinguished by Cicero ('Topica,' 2) from Topic. "All exact argumentation," he observes, "consists of two parts, one comprehending invention (unam inveniendi), and the other judgment (alteram judicandi)." He assigns to Aristotle pre-eminence in both, and speaks of the Stoics as having especially applied themselves to the latter, which they named Dialectic. But the dialectic of the Stoics was certainly not confined to pure logic, as appears from what Cicero says in his treatise 'On the Orator' (ii. 38), and also from the statement of the Stoical opinions as to dialectic by Diogenes Laertius, in his Life of Zeno of Citium. The Stoic dialectic seems to have comprehended logic and more, as will hereafter appear; and yet it comprehended less than the logic of the Peripatetics.[*]

In Dr. Whately's treatise, as may be collected from a comparison of various passages, logic seems to be convertible with syllogistic. To *reason*, in the strict sense of the word, is to make use of arguments (p. 18); an argument, when regularly expressed, is a syllogism (p. 55); and logic is the science and the art of reasoning (p. 1); from which it follows that to syllogise and to reason are convertible, and that logic is the theory of the syllogism (p. 73).[†] This seems to be the meaning of the author, and if such be the proper notion of logic, it must be admitted that the boundaries of the science are very limited indeed. But limited as they really are, in this view of the subject, the exercise of reducing argumentation to syllogistic forms still contains more than those may be inclined to suppose who have not been disciplined in this practice.

It may be worth while to notice what Dr. Whately says of the word *argument*. "Every argument," he observes, "consists of two parts, that which is proved, and that by means of which it is proved;" and he adds in a note, that this is the strict technical sense of the word argument, but that in popular use argument is often employed to denote the latter of these two parts alone. But this is a mistake: the popular use is the correct use, as it is in many other cases. When a man is said to use a good argument, he urges or suggests something which is either proved or universally admitted, and the goodness of his argument consists in its being applicable to the matter in hand, and obviously comprehending within it something which it is his object to establish or prove. He who argues well, possesses the inventive faculty as defined by Cicero. It is his business to establish one or more things, and to command the assent of his hearers by presenting to their minds such propositions as only need to be presented in order to command assent, and which are comprehensive enough to embrace the particular things which he has to establish. The argument, in the popular sense, is the premises of the syllogism; or it is the middle term; and it is accordingly explained by Cicero ('Topica,' 2) to be "ratio, quæ rei dubiæ faciat fidem," the *reason*, which gives credibility to a thing that is doubtful. Of course that which is proved, or to be proved, cannot be an argument within Cicero's meaning of the term. Dr. Whately himself says, "that which is used to prove the question, if stated *last* (as is often done in common discourse), is called the *reason*." But it is equally the reason whether placed first or last, and is called the *reason* with strict technical propriety, whatever may be the place which it occupies in discourse. The proper name for the syllogism is argumentation, of which the two premises are the argument; and this is the sense in which ancient logical writers understood argumentation and argument.

The meaning of the term Logic is explained by Kant with his usual clearness. Logic is the science of the laws of thought. Logic may be considered from two points of view, as General or Special. General logic comprehends only the necessary laws of thought, without which there can be no exercise of the Understanding, and it has no reference to any difference in the objects to which it is applied. Special logic comprehends the rules of thinking rightly on any given subject. General logic again is either Pure or Applied logic. In the former we abstract from all empirical conditions under which our understanding is exercised, as for instance, the influence of the senses, imagination, memory, &c. A General and Pure Logic has consequently only to deal with pure *à priori* principles, and is a canon of the Understanding and of the Reason, but only in respect to the formal part of its use; the matter which is its object may be either empirical or transcendental. A General Logic is called Applied when it has reference to the rules of the exercise of the Understanding under the subjective empirical conditions, which we learn from psychology. It has consequently empirical principles, though it is so far General that it has reference to the exercise of the understanding without any distinction of objects. In General Logic consequently, the part which comprehends the pure doctrine of the Reason must be absolutely separated from that which is Applied, though still General Logic. The first part only is properly a science, though brief and dry, as the regular exhibition of an elementary view of the Understanding must be. In this science then logicians must always bear two rules in mind:—

1. As General Logic, it abstracts from everything which the understanding contains as knowledge, and from all differences in its objects, and it has only to do with the pure form of thought.

2. As Pure Logic, it has no empirical principles, and consequently derives nothing (as has been sometimes supposed) from psychology, which therefore has no influence at all on the canon of the understanding. It is a demonstrated science, and everything in it must be absolutely *à priori* true. (Kant, 'Critik der Reinen Vernunft,' p. 55, &c., ed. 1828.)

By Applied Logic, Kant understands an exhibition of the understanding and the rules of its necessary exercise *in concreto*, namely, under those accidental conditions of the subject which may assist or impede its exercise, and all which are only empirical data. It treats of attention, its impediments and consequences, the origin of error, the state of doubt, conviction, &c.

General logic then abstracts from all our knowledge, that is, from all relation of our knowledge to an object, and contemplates only the logical form in the relation of the parts of our knowledge to one another, that is, the form of thought generally. So far as truth is concerned, since logic is conversant only about the general and necessary rules of thought, the criterion of its truth must lie in these rules; and whatever contradicts them is false, for logic would then contradict itself. Yet though a logic may be consistent, that is, not self-contradictory, yet it may be contradictory to the object; consequently the bare logical criterion of truth, namely, the conformity of knowledge with the general and formal laws of thought and of the reason, is the *conditio sine quâ non*, and consequently the negative condition of all truth. Further however logic cannot go, and any error which affects not the form, but the matter, logic has no means of detecting.

A recent German writer has viewed logic in a somewhat different light, and given it a wider range. The difficulty of presenting anything like an adequate view of the principles of Hegel by a few extracts must be the apology for this imperfect attempt; the obscurity of the exposition, if such it shall appear, may be partly though not entirely due to ourselves.

"That which is generally understood by the term logic, is viewed altogether independent of any metaphysical signification. In its present condition this science has no subject-matter (inhalt) in the sense in which subject-matter is considered as a reality and as a truth in the ordinary acceptation of the term. But it is not for this reason a formal science which is devoid of truth. The region of truth however must not be sought for in that material which people expect to find in logic, and to the want of which its unsatisfactory nature is usually attributed; but the emptiness of logical forms rather lies in the way in which they are considered and handled. So far as logical forms, considered as determinate notions, are disjointed from one another, and not bound together in organic unity, they are dead forms, and have not in them the spirit which is their living concrete unity. Thus viewed, they have no solid subject-matter (inhalt)—no matter which of itself would be a real substance (gehalt). The subject-matter which is looked for in logical forms is nothing else than a firm foundation and concretion of these abstract determinations; and such a substantial essence is usually sought for beyond the bounds of the science. But the logical reason is itself the Substantial or Real matter, which unites in itself all abstract determinations, and is their solid absolute concrete unity. There was no need then to look far for a subject-matter, as it is usually called; it is not the fault of logic if it appears empty, but it is the fault of the way of considering it."

---

[*] See also the threefold division of Philosophy by Diogenes Laertius (*Proœmium*), into Physic (φυσικόν), Ethic (ἠθικόν), and Dialectic (διαλεκτικόν). Zeno of Elea was considered as the founder of dialectic.

[†] Dr. Whately says, "The third operation of the mind, namely, reasoning (or discourse) expressed in words, is *argument*; and an argument stated at *full length* and in its regular *form*, is called a syllogism; the third part of logic therefore treats of the *syllogism*." The other two parts, which are briefly treated by Dr. Whately, are—c. 1, "Of the operations of the mind and of terms;" and c. 2, "Of propositions," but they are very incomplete, and, as we think, very deficient in logical precision. There is a Supplement to c. 1.

"In forming judgments and conclusions, when the operations are especially referred to and grounded on the quantity of the notions, everything rests in an external difference, in a mere comparison, and becomes a pure analytical process and calculation void of all ideas. The deduction of the so-called rules and laws of conclusions in particular, is not much better than a handling of sticks of different lengths in order to sort them out and tie them up according to their magnitude —nothing else than the child's game of selecting and putting together the pieces of a picture which is composed of parts. This exercise of thought has accordingly not unaptly been compared with arithmetic, and arithmetic has been compared with it. In arithmetic, numbers are considered independent of any notions, as something which, independent of their equality or inequality, that is, independent of their absolute external relation, have no signification, as something which neither in themselves nor in their relations express a thought. When it is mechanically ascertained that $\frac{3}{4}$ multiplied by $\frac{2}{3}$ make $\frac{1}{2}$, this operation contains just as much and just as little thought as the ascertainment whether in a given figure this or that conclusion can be made."

Hegel remarks, that with respect to the formation of an individual mind, logic may be compared with grammar. Both logic and grammar are something different for him who first approaches them and science in general, and for him who comes back from the sciences to them. He who begins to learn grammatical forms and rules, sees in them nothing but themselves: he who has mastered a language, and compares it with other languages, is in a capacity to understand the full force of these rules and forms. Through the grammar he can reach the expression of the mind, the logic. The case is the same with a man's first introduction to logic: its signification is limited to itself. Logic must be first learned as something which a man comprehends and understands, but in which extent, depth, and further meaning are not discovered. It is not till we have a deeper acquaintance with the other sciences that the logical becomes for the mind, subjectively, not a mere abstract universal, but a universal which comprehends within it the abundance of the particular: just as the same moral maxim in the mouth of a youth, even if he understands it correctly, has not the signification and the comprehensive meaning which it has in the mind of a man of long experience, to whom the words convey the full force of the expression. Thus the logical cannot be fully estimated until it is made the result of experience in the sciences: it then presents itself to the mind as the universal truth, not as a particular knowledge coexistent with other matter and realities, but as the essence of all other knowledge.

"Logic has been defined (by Hegel) as the science of the pure thought, which has for its principium (*princip*) the pure knowledge (*wissen*); not an abstract, but a concrete living unity; and concrete in this way, that in it there are undeniably opposed to one another the consciousness of a subjective self-existence, and a second such existence, an objective; and that existence is known as a pure Notion in itself, and the pure Notion is known as the real existence. These then are the two moments which are contained in the logical. But they are only known as existing inseparably, and not each in the consciousness as existing by itself; but it is only by virtue of their being also known as different (yet not self-existing) that their unity is not abstract, empty, and inactive, but concrete.

"This unity constitutes the logical principium (*princip*) as its element, so that the development of this difference, which is always in it, takes place *within* this element. Thus the entire notion is to be considered in the one case as existing Notion, in the other as Notion simply: in the former case it is notion by itself of reality or existence; in the latter it is notion as such, self-existing notion.

"Logic will therefore be divided into the logic of the notion as existence, and of the notion as notion; or, to make use of the common though very indefinite and ambiguous expressions, into the objective and subjective logic.

"Consistently with the fundamental element of the unity of the notion in itself, and the connected inseparability of its momenta, these momenta must be viewed also in their mutual relations, so far as they are different, and so far as the notion is considered with respect to a difference. Hence arises a sphere of Mediation (*vermittlung*), or of the notion as a system of reflective determinations, that is, of the existence passing into the internal existence of the notion, which, in this way, is not viewed as such *by itself*, but is affected by the immediate existence as by a thing properly external to itself." This is the doctrine of the essence (*wesen*), which stands between the doctrine of existence and of the notion; but in the general division of Hegel's work it is placed under the objective logic, inasmuch as, though the essence is certainly the Internal, yet the character of the subject is expressly appropriated to the Notion.

Hegel's division, therefore, is into the objective and subjective, or, more distinctly, into:—

1. The Logic of Existence (*Die Logik des Seyns*).
2. The Logic of Essence (*Die Logik des Wesens*).
3. The Logic of the Notion (*Die Logik des Begriffs*).

('Wissenschaft der Logik,' *erster band*, 1832.)

It may be useful to show in a general way what the Organon of Aristotle, as we now have it, contains. The name Organon, or Instrument, was not given by Aristotle, but is of a date posterior to him.

The following synopsis is given by Giulio Paci, in his edition of the Organon:—

Logic is conversant about the Syllogism. Accordingly the Organon explains,	1. The Parts of a Syllogism.	With reference to primary Notions		The CATEGORIES.
		With reference to secondary Notions		On INTERPRETATION.
	2. The Syllogism.	Generally		The PRIOR ANALYTICA.
		Specially.	Demonstrative	The POSTERIOR ANALYTICA.
			Dialectic	The TOPICA.
			Sophistic	On SOPHISTIC ELENCHI.

With this tabular view, the following general description of the contents of the Organon of Aristotle, by an able writer, will be intelligible. "The incorrect notions which have prevailed, and still continue to prevail, in regard to the 'nature and province of logic,' are, without detraction from his merits, mainly to be attributed to the example and authority of the philosopher himself. The books of *Categories*, as containing an objective classification of real things, is metaphysical, not logical. The two books of *Posterior Analytics*, as solely conversant about demonstrative or necessary matter, transcend the limits of the formal science; and the same is true of the eight books of *Topics*, as wholly occupied with probable matter, its accidents and applications. Even the two books of the *Prior Analytics*, in which the pure syllogism is considered, are swelled with extralogical discussions. Such for example, is the whole doctrine of modality of syllogisms, as founded on the distinction of pure, necessary, and contingent matter; the consideration of the real truth or falsehood of propositions, and the power so irrelevantly attributed to the syllogism of inferring a true conclusion from false premises; the distinction of the enthymeme through the extra formal character of its premises, as a reasoning from signs and probabilities; the physiognomic syllogism, &c. &c. The same is true of the book on *Interpretation* (περὶ Ἑρμηνείας); and matters are even worse with that on *Fallacies* (*Sophistic Elenchi*). If Aristotle, therefore, did more than any other philosopher for the progress of the science, he also did more than any other to overlay it with extraneous lumber, and to impede its development under a precise and elegant form. Many of his successors had the correctest views of the object and scope of logic; and even among the schoolmen there were minds who could have purified the science from its adventitious sediment, had they not been prevented from applying their principles to details by the implicit deference then exacted to the precept and practice of Aristotle." ('Edinburgh Review,' April, 1833.)

It may indeed be strongly suspected that the various treatises which compose the Organon contain interpolations. Further, what we now have are only a part of the logical works of Aristotle; and even this part does not exhibit simply a logical system, properly so called, but rather a system of argumentative discourse.

We may remark of the Categories that attempts have been made to found a philosophical system upon them, as explained by Aristotle. They contain, as is observed by Dr. Whately, the explicit statement that though a primary substance signifies a particular thing, as "a particular man," "a particular horse," the general term "man" or "horse" (which he calls a secondary substance) only *appears* to denote a particular thing, but in fact does not; for the thing is not one, as in the case of a "particular man," but is said of many (v. 16, ed. Pac.). This is a clear statement that general terms do not indicate realities, but are only the expression of the mode in which the mind is affected.

In the Prior Analytics it has been stated that the pure syllogism is considered: the introductory chapter of the First Book states in a general way the objects of the science as conceived by Aristotle, and is expressed with his characteristic clearness.

"It is proper," says Aristotle, "first to state about what the inquiry is, and to what the inquiry belongs, namely, demonstration and demonstrative science. Then we must define Proposition (*πρότασις*), Term (*ὅρος*), and Syllogism (*συλλογισμὸς*); and what is a perfect and what an imperfect syllogism. Next, what is meant by one thing being or not being in the whole of another, and what we mean by a thing being predicated of all or none. A proposition then is a sentence (*λόγος*) which affirms or denies something of another thing; and this either universally, or particularly, or indefinitely. By universally, I mean where it applies to all or none; by particularly, where it applies to part, or not a part, or not to all; and by indefinitely, where it applies, or does not apply, without anything being determined as to the whole or part. The demonstrative (ἀποδεικτική) proposition differs from the dialectic (διαλεκτική). The demonstrative is an assumption of one side of the question, namely the contradiction; for he who demonstrates does not interrogate, but he assumes; but the dialectic is an interrogation as to the contradiction.* This, however, makes no difference with respect to the syllogism in either case, for both he who demonstrates and he who interrogates syllogise by assuming something to be predicated or not to be predicated of another thing. Consequently a syllogistic proposition will be simply an affirmation or denial of one thing with respect to another, in the way already mentioned; and a proposition will be demonstrative if it is true, and obtained by means of the original hypothesis. A dialectic proposition is, with respect to the question, an interrogation about denial; but to him who syllogises, it is the assumption of that which is apparent and probable, as it is shown in the Topica. What then is a proposition, and in what respect a syllogistic, demonstrative, and dialectic proposition differ, will be accurately stated in what follows (in the 'Analytica Posteriora'); but for the present purpose what has been already said is sufficient.

"I call Term that into which a proposition is resolved, as the predicate (*τὸ κατηγορούμενον*), and that of which predication is made, with the addition or not of 'being,' or 'not being.' A syllogism is discourse, in which certain things being laid down, something different from these things necessarily results by virtue of these premises (*τῷ ταῦτα εἶναι*). And I mean by the words 'by virtue of the premises,' that this something results by reason of them (*διὰ ταῦτα*): and 'by reason of them' means that no other term is needed in order to this necessary result. Now, I call that a perfect syllogism which requires nothing else besides what is assumed or granted in order that the necessary conclusion may appear. I call that an imperfect syllogism which requires one or more things which are of necessity by virtue of the given terms, but are not assumed in the propositions. For one thing to be said to be in the whole of another, and one thing to be predicated of the whole of another, is the same thing; and I mean by predication of the whole of a thing, when one cannot conceive any part of the one thing (the subject) of which the other cannot be predicated; and the like when the predication is of no part of a thing."

It was apparently the object of Aristotle in his so-called logical treatises, as we now have them, to make a perfect system of argumentative discourse, and not merely a logical (properly so called) system. It is probable that if all his works of this class were extant and arranged according to his own method, we should see still more clearly that the whole was not considered a logical system (as the term logic is strictly understood), but that a logical system (as the term is strictly understood) was contained in it. Whether Aristotle or any other person put the existing books of the Organon together, neither the author who conceived them in connection with one another, nor any one else, considered them as forming a pure logical or even a pure dialectic treatise, but a treatise on argumentation. And this is clear enough from an examination of the contents of the Organon, and the remarks of Cicero (*Topica*) and his commentator Boethius, who was himself a writer on logic. Boethius, who uses the term *Logic*, informs us that the Peripatetics understood this term as Cicero understood it, and Cicero defines it to be "disserendi diligens ratio," or "an exact method of argumentation." The Peripatetics, he adds, understood logic to consist in invention and judgment; but the Stoics, who neglected invention, considered it to consist in judgment only, which they distinguished by the name of dialectic. Thus the logic of the Peripatetics was larger than the logic of the Stoics. The logic of the Peripatetics consisted, first of topic or invention, which teaches the method of easily discovering arguments; and Boethius remarks that Aristotle in his 'Topica' treats of the "maximæ propositiones" (called *loci*), which are universal propositions, of undoubted truth, which need no demonstration, or probable propositions, and from which we descend to the conclusions of the syllogism. Judgment is more particularly exercised in making conclusions (in colligendi ratione), but inasmuch as all argumentation and syllogising depend on and are constructed of propositions, we have to consider both the matter of propositions and their connection. As to the *matter*, we have to consider whether the propositions are true, or necessary, or probable, or sophistical. As to the connection, we have to consider the union and the composition of the propositions, which may be called the *form* of the arguments. Logic then consists of invention, and of the conclusions from invention, or the form of the argumentation. The part which treats of invention supplies the instruments or means for invention, and, as already observed, is called Topico. The part which relates to judgment supplies certain rules for discerning or separating (*discernendi*), and is called Analytice: so far as it treats of the connection or union of propositions, it is called Analytice Prior; so far as it treats of the inventions themselves, it is called Analytice Posterior, when it is engaged about discerning necessary arguments; but when it is engaged about false and deceptive arguments (*cavillatoria*), that is, sophistical, it is called the Elenchi. Boethius then concludes that Aristotle treated of logic in a more complete manner than the Stoics, "since he treated of the two things besides which there is no third, namely, invention and judgment, while the Stoics neglected invention and only furnished us with the instruments of judgment."

This statement of what the logic of Aristotle was, may help to remove certain long-rooted mistakes on the matter. Dr. Whately, who confines logic to the pure syllogism in his theoretical view of the subject, though not in his practical exposition of it, says that "with the exception of Aristotle, hardly a writer on logic can be mentioned who has clearly perceived, and steadily kept in view throughout, its real nature and object." And he remarks that even Aristotle is *not entirely* exempt from the error of mistaking the nature of logic, and extending it to subjects with which it has no proper connection. Now the fact is that Aristotle's logic, being what we have here explained it to be, is a very different thing from what it appears to be considered to be by many. To say that Aristotle is *not entirely* exempt from the error above mentioned is rather a singular expression, when three-fourths of his Organon have nothing at all to do with the pure syllogism. In fact Aristotle's Organon, and his logic as explained by Boethius, are much more like Watts's much-abused 'Right Use of Reason' than like what many modern writers take them to be.

There is a short but not a satisfactory account of the contents of Aristotle's Organon by Dr. Thomas Reid, Edinburgh, 1806. It may however serve to give the reader some notion of the contents of the work. The best account of it is said to be by Barthélemy St. Hilaire, 'La Logique d'Aristote,' 2 vols. 8vo. [LOGIC.]

The controversial tone of this article, in a work of this description, may require a word or two of apology. Until the limits of logic are better defined, the subject must be controversial, for the question "What is Logic?" must continually recur. The work with reference to which these remarks are chiefly made has long had a great circulation, and has taken the place of former treatises, which is a sufficient reason why the errors of that work, if such they be, should be pointed out. In various parts of his work, Dr. Whately has explained with sufficient precision what he considers Logic to be: he has in fact defined it as the pure syllogism, irrespective of all material considerations. But in the execution of his plan he continually perplexes the reader with considerations as to the matter of propositions and terms; and he transcends the narrow limits within which the science, as he understands it, is confined. It cannot be supposed that a writer, however able, can so far deviate from a scientific method without serious prejudice to his work.*

Two reviews of Dr. Whately's treatise have fallen under our notice, one of which appeared in the 'Westminster Review' for January, 1828; the other in the 'Edinburgh Review' for April, 1833. The former shows that Dr. Whately is not alone in some of those opinions which we consider erroneous. The latter is from a master-hand [Sir W. Hamilton], who is well acquainted with both ancient and modern writers on logic and philosophy. To this article we are much and deeply indebted.

Several treatises on logic have appeared in Germany, which profess to exhibit the subject according to a strictly scientific method. Among these may be mentioned Kiesewetter's 'Grundriss einer Allgemeinen Logik nach Kantischen Grundsätzen,' &c., Berlin, 1791.

A complete catalogue of logical treatises would be very long; and the value of the catalogue would hardly compensate for its length. Writers have formed their notions of the science with more or less precision, but have seldom, if ever, kept within their own limits; and this is a difficulty which is inherent in the subject. If confined to the bare affirmation or negation of propositions expressed by *is* or *is not* (considered simply as determinations of quantity), and to the pure syllogism, the theory of logic is soon exhausted, and as a science it is comprised within very narrow limits. If we once transcend those bounds, we enter into a wider sphere, in which this formal logic becomes a mere point. To ascertain the full import of the words *is* and *is not* in a proposition is the highest aim of philosophy.

A student in logic, consulting only modern works, may be debarred from even the slightest notion of an historical view of the subject, by the mixture which his books give him of the ideas of writers of all times and countries. To disentangle the confusion of minds and methods which even a good treatise presents, *historically* speaking, it is above all things necessary that he should first get some knowledge of what Aristotle is. And this the work of an erudite and acute German writer enables us to give in a very useful way.

The 'Elementa Logices Aristotelicae,' by Professor Trendelenburg, Berlin, 1842, 2nd edition, consists of passages selected from the works of Aristotle, which passages may be considered as containing the elements of the science. These passages are so arranged as to present a kind of outline of the whole logical system of Aristotle. They are intended for the use of the higher classes in gymnasia, and as a preparation for philosophical studies.

The following article is simply a translation of these extracts, which are retained in the order given to them by Trendelenburg; and the references to the original places in Aristotle have also been retained. The original terms of Aristotle are also given in brackets the first time that each is mentioned.

---

* *Τὴν διαλεκτικὴν ἐπιστήμην οὖσαν τοῦ ὀρθῶς διαλέγεσθαι περὶ τῶν ἐν ἐρωτήσει καὶ ἀποκρίσει λόγων.* (Diog. Laert., 'Zeno,' vii., c. 34.)

* The edition of Dr. Whately's 'Logic,' referred to in this article is the fourth. The writer [1840] did not know that there was a sixth, which contains some few alterations, till this article was ready for the press. The reader should refer both to the fourth and to the sixth editions.

In the preface to another useful work ('Erläuterungen zu den Elementen der Aristotelischen Logik,' Berlin, 1842, by the same author), he has more fully explained his views in making these extracts from Aristotle, and the following remarks are his:—At the time of the Reformation Luther saw clearly the advantage of logical instruction in the higher schools, and he viewed it correctly as the completion of the grammatical instruction. The circle of studies in modern times has been wonderfully enlarged, and it has been found necessary to extend the school instruction to meet the wants of the present age. But the great variety of subjects with which our present systems of education occupy us, only render it the more necessary to discipline the mind in such a manner that it shall see a unity in all that is presented to it, and not be bewildered by the variety of objects whose connection escapes us, when they are contemplated separately. Such a discipline is furnished by a good course of elementary instruction in logic. For this purpose the author has adopted the genuine words of Aristotle, in which the philosopher has laid down his elementary logical principles. The logic of Aristotle is not antiquated, though it is both misunderstood by some, and blamed by others who do understand it. It is not the formal logic of Kant, which would confine us to the forms of thought without any reference to the object into which the thought penetrates. Such a limitation of the subject is entirely at variance with the system of Aristotle, and opposed to its real character. "We have," says Trendelenburg, "attempted to restore this real character, and thus brought Aristotle nearer to the objective demands of modern times." Those who view logic as purely formal, view it differently from Aristotle, and they may consider their mode of viewing the subject to be better than his. Those who say that Aristotle has, in some matters, erroneously extended the province of logic to things beyond its limits, and has not always kept close to the real subject, appear to have conceived that he viewed it merely as formal, and sometimes transgressed the boundaries of the science which he recognised. This is however an erroneous view of Aristotle's system.

The advantage of studying these elementary principles in the words of Aristotle is, that in his writings the language of philosophy is formed into a scientific terminology, which is the basis of that which we now use. We cannot therefore lay a sure foundation for our logical and philosophical studies on any other basis than a full comprehension of the meaning of Aristotle's terms.

The author remarks that a learner of logic there meets with those fundamental notions (begriffe) in their simple nakedness, which lie hidden in all our knowledge and govern it. As these notions are hid or concealed in our knowledge, they appear dry and lifeless when they are produced in their naked form. It is therefore the business of the teacher to show to the pupil their real significance, to make him see their actual value in their application. Now the instruction in the German Gymnasia, as in the higher schools in Great Britain and Ireland, is in the learned languages and in mathematics; and accordingly the teachers in both these departments, if they are to make use of such a work as Trendelenburg's, must be able to apply logical principles to instruction in language and in mathematics. To facilitate this method of instruction is the object of the learned author in the 'Illustrations (Erläuterungen) to the Elements of Aristotle,' not, as he modestly observes, that this is precisely the form in which he supposes that they ought to be presented to the pupil, but "merely to render clear the fundamental notion of the logical relationship in the objects of scientific observation."

The mode in which the author suggests that his two works should be used is probably the best; but they cannot be used at all in ordinary instruction, except under the guidance of a competent teacher. They will however be useful to those who have a competent knowledge of the Greek and German languages, and possess some elementary notions of logic; and those who cannot read Greek with facility will probably find the following translation sufficiently exact to give them the meaning of Aristotle. A translation of such extracts is not easy, and it is possible that there may be some errors in it. A careful study of these extracts however will convince a student how meagre and unsatisfactory an exhibition of the elementary principles of logic even our best works on the subject contain.

Outlines of Logic.

(1.) In things in which there is both falsehood and truth, there is a composition of ideas as though they were one. ('De Anim.,' iii. 6.) For falsehood and truth are concerned with composition and separation. Accordingly nouns and verbs by themselves resemble the idea without composition and separation, as "man" or "white," when nothing is added: for there is so far neither falsehood nor truth. ('De Interpret.') Consequently he thinks truly who considers that which is separated to be separated, and that which is compounded to be compounded; but he thinks falsely whose thoughts have a different relation from that which the things have. ('Metaph.,' ix. 10.)

(2.) All speech (*λόγος*) is significative, but not all enunciative (*ἀποφαντικός*), but only that in which there is either truth or falsehood. But it is not in all; for example, prayer is speech, but neither true nor false. The enunciative alone belongs to the present inquiry. ('De Interpret.,' c., 4.)

(3.) Of things said with no connection, each signifies either substance (*οὐσία*) or quantity, or quality, or relation, or where (space), or when (time), or position, or possession, or acting, or being acted on. And substance (*οὐσία*) is, to give an example, such as man, horse: and quantity is, such as two cubits, three cubits: and quality, such as white, grammatical: and relation, such as double, half, greater: and where, such as in the Lyceum, in the agora: and when, such as yesterday, last year: position, such as he is lying, he is sitting: and possession, such as he has shoes on, he is armed: and acting, such as he cuts, he burns: and being acted on (*πάσχειν*), such as he is cut, he is burnt. ('Categ.,' c. 4.)

(4.) Simple enunciative speech is firstly an affirmation, secondly a negation. And affirmation (*κατάφασις*) is an enunciation of something towards another thing; and negation (*ἀπόφασις*) is the enunciation of something away from another thing. And the speech is true in like manner as the things are true. ('De Interpret.' c. 5, 6, 9.)

(5.) "Not-man" is not a noun; for indeed there is no name to call it by; for it is neither affirmative speech nor a negation. But let it be called "name or noun indefinite," (*ἀόριστος*) because it can be said equally of anything, both of what is and what is not.

Every affirmation and negation will consist either of a noun and a verb or of an indefinite noun and a verb. But without a verb there is neither affirmation nor negation. ('De Interpret.,' c. 2, 10.)

(6.) Of things some are universal and some particular. I call that universal (*καθόλου*) which can be said of more things (than one); and I call that particular (*καθ' ἕκαστον*) which cannot: thus, man belongs to the universal, and Callias to the particular. ('De Interpret.,' c. 7.) A Proposition (*πρότασις*) then is speech either affirming or denying something about something. And this speech is either universal or particular (*ἐν μέρει*), or indefinite (*ἀδιόριστος*). I call that universal which belongs either to all or to none; I call that particular which belongs either to some one, or not to some one, or not to all; and I call that indefinite which either belongs or does not belong, without the universal or particular, as, for instance, of opposite things that there is the same science, or that pleasure is not a good. ('Analyt. Pr.,' i. 1.)

It is very evident that the universal is more efficient, because, knowing the first of two propositions, we know in a manner the second also, and have it potentially; for example, if a man knows that the angles of every triangle are together equal to two right angles, he knows in a way that the angles of an isosceles triangle also are together equal to two right angles potentially (*δυνάμει*), even if he does not know that the isosceles triangle is a triangle. But he who knows this proposition (the second) by no means knows the universal, either potentially or in reality (*ἐνεργείᾳ*). And the universal is an object of the intellect; but the particular terminates in the sensuous perception. ('Analyt. Post.,' i. 24.)

(7.) Every proposition belongs either to what is, or to what must be, or to what can be. ('Analyt. Pr.' i. 2.)

(8.) Of all things indeed which exist there are some of such a kind that they can be predicated with truth universally of nothing else, such as Cleon, Callias, and a single thing, and what is an object of sense; but of these things others can be predicated (for each of these persons is both man and animal); and some things are themselves predicated of other things, but of them there is no further predication by other things; and some are both themselves predicated of others, and others of them, for example, "man" is predicated of "Callias," and "animal" of "man." Accordingly that there are some things which exist which cannot be predicated of anything is manifest. For of sensuous objects nearly every one is such that it can be predicated (*κατηγορεῖσθαι*) of nothing. ('Anal. Pr.' i. 27.)

The genera (*γένη*) are predicated of the species, but not the converse the species (*εἴδη*) of the genera. ('Categ.' c. 5.)

(9.) It is impossible for the same thing at the same time to belong (*ὑπάρχειν*) and not to belong to the same thing and in the same manner. This indeed of all principles is the most certain; for it is impossible for any one to conceive that the same thing is and is not. Wherefore all who demonstrate, carry back (their demonstration) to this ultimate notion. ('Metaphys.' iv. 3.)

Every thing which is true must agree with itself in every way: for with truth all which is true is in harmony, but with falsehood the truth is soon at variance. ('Eth. Nic.' i. 8.)

(10.) And since it is possible for what belongs to be enunciated as not belonging, and what does not as belonging, and what belongs as belonging, and what does not belong as not belonging, and with respect to other times than the present in like manner, it is possible to deny both all that a man has affirmed, and to affirm what he has denied. So that it is manifest that to every affirmation a negation is opposed, and to every negation an affirmation; and let the contradiction (*ἀντίφασις*) be this, affirmations and negations opposed.

And I call opposition (*ἀντικεῖσθαι*) the contradiction of the same thing about the same thing, but not *ὁμωνύμως*. (Comp. 'Categ.,' c. 1; 'De Interpret.,' c. 6.)

Contradiction is opposition (*ἀντίθεσις*) in which there is no mean in itself. And as parts of contradiction, there is on one side affirming something of something, and on the other side denying something from (ἀπό) something. ('Analyt. Post.,' i. 2.)

In affirmation and negation always, whether it is a thing that exists or does not exist, the one will be false and the other true: for of the two that Socrates is sick and that Socrates is not sick, when Socrates exists, it is manifest that one of them is true and the other false, and if he does not exist in the same manner: for that he is sick, when he does not exist, is false, and that he is not sick is true.

Accordingly, to these things alone, which are opposed as affirmation and negation, it will be peculiar for one of them always to be true or false. ('Categ.,' c. 10.)

(11.) Things included in the same genus which differ most from one another, are defined to be contrary (ἐναντία). ('Categ.,' c. 6.)

(12.) Therefore I say that affirmation is opposed to negation in the way of contradiction, when the one signifies that a thing is universal and the other signifies that the same is not universal: as for example, every man is white—not every man is white; no man is white—a certain man is white. And I say that the universal affirmation and negation are opposed as contraries: as for example, every man is white—no man is white; every man is just—no man is just. Therefore it is not possible for these to be true at the same time. ('De Interpret.,' c. 7.)

(13.) And I say that propositions opposed are in common expression (κατὰ λέξιν) four—namely, all and none, all and not all, some and none, some and not some; but in truth three; for some is opposed to not some merely in expression. And of these three propositions the universal, all and none, are contrary: for example, all knowledge is excellent, no knowledge is excellent; but the other propositions are opposed (as contradictory). ('Analyt. Pr.,' ii. 15.)

(14.) And since every proposition is either of being or of necessarily being or of the possibility of being, and of these some are affirmative and some negative in every mode, and again of the affirmative and negative propositions some are universal and some particular and some indefinite, of necessity the proposition which is universally negative can be converted (ἀντιστρέφει) in its terms (ὅροι): for example, if no pleasure is a good thing, neither is any good thing pleasure; but the affirmative proposition must be converted, not indeed universally but particularly; thus if all pleasure is good, some good also is pleasure. And of particular propositions the affirmative proposition must be converted particularly, for if some pleasure is good, some good also is pleasure: but as to the negative, it is not of necessity, for, if "man" does not belong to (cannot be predicated of) some animal, it does not follow that "animal" cannot be predicated of "some man." ('Analyt. Pr.,' i. 2.)

(15.) The things which are sought are equal in number to the things which we know. And we seek four things—the That, the Why, If it is, What it is. (τὸ ὅτι, τὸ διότι, εἰ ἔστι, τί ἐστίν.) For when we seek whether this or that is, referring it to number, for example, whether the sun is eclipsed or not, we seek the That. And there is proof of this; for when we have found out That it is eclipsed, we cease inquiring; and if from the beginning we know That it is eclipsed, we do not inquire whether it is. And when we know that it is, we inquire the Why: for example, when we know that the sun is eclipsed, and that the earth moves, we inquire Why the sun is eclipsed, or Why the earth moves. These things accordingly we inquire after thus; but some things we inquire after in another manner, as for example, Whether there is or is not Centaur or God. I simply mean if there is or is not, but not if he is white or not. And when we know that there is, we inquire What it is, for example, What is God or what is man. ('Analyt. Post.,' ii. 1.)

(16.) To know That a thing is and to know Why it is are different; and the knowledge of the Why refers to the first cause. The chiefest of knowledge is to contemplate the Why. ('Analyt. Post.,' i. 13, 14.)

(17.) And we think that we know each thing simply when we think that we both know the cause by which the thing is, that it is its cause, and that it cannot be otherwise. ('Analyt. Post.,' i. 2.)

(18.) All instruction and all rational learning come from knowledge preceding. And this is manifest to them who contemplate all (sciences); for both those of the sciences which are mathematical by these means exist, and every one of the other arts. ('Analyt. Post.,' i. 1.)

(19.) And things are prior and better known in two ways: for it is not the same thing to be prior by nature and prior as regards us, nor yet to be more known by nature and more known by us. And I call those things prior and more known as regards us which are nearer the sense, but I call simply prior and more known those things which are farther from the perception. And the farthest off are the most universal, and the nearest are the particular. ('Analyt. Post.,' i. 2.)

(20.) We get certainty in all things either by syllogism (συλλογισμός) or by induction (ἐπαγωγή). ('Analyt. Pr.,' ii. 23.)

We learn either by induction or demonstration (ἀπόδειξις); and demonstration proceeds from the general, but induction from the particular. ('Analyt. Post.,' i. 18.)

(21.) And syllogism is speech, in which when some things are laid down, something else different from what are laid down results by virtue of their being laid down; and by virtue of their being laid down I mean that it results through them; and I mean by resulting through them, that there is no need of any external term for the necessity to be. ('Analyt. Pr.,' i. 1.)

(22.) And I call Term that into which the proposition is resolved, as the predicate and the thing of which it is predicated (subject). ('Analyt. Pr.,' i. 1.)

(23.) Whatsoever is affirmed of the predicate (τοῦ κατηγορουμένου), will be affirmed of the subject (τοῦ ὑποκειμένου) also. ('Categ.,' c. 5.)

(24.) When three terms are so related to one another that the last is in the whole of the middle, and the middle is either in or not in the whole of the first, of necessity there is a perfect syllogism of the extremes. And I call middle (μέσον) that which is both itself in another and another in it, and which also by position becomes middle: And I call extremes (ἄκρα) both that which is in another, and in which another is. For if A can be predicated of all B, and B of all C, necessarily A can be predicated of all C. And I call a figure (σχῆμα) of such description the first. ('Analyt. Pr.,' i. 4.)

(25.) And when the same thing belongs to all of one thing and to none of another, or to all or none of each, such a figure I call the second, and that which is predicated of both I call the middle term in it—And the middle term is placed without the extremes, but the first in position—And a syllogism will be possible both when the terms are universal and when they are not universal. When they are universal, there will be a syllogism, when the middle is in all of one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

For let M be predicated of no part of N, but of all X. Since then the negative proposition can be converted, N will belong to no part of M: but M by the supposition was predicated of all X. Accordingly N will be no part of X: for this has been shown before. Again, if M shall belong to all N, but to no part of X, neither will N belong to any part of X: for if M belongs to no part of X, neither will X belong to any part of M: but M by the supposition belongs to all N. Therefore X will belong to no part of N: for this also has become the first figure. And since the negative proposition is convertible, (ἀντιστρέφει) neither will N belong to any part of X, so that there will be the same syllogism. An affirmative syllogism is not produced by means of this figure, but they are all negative, both the universal syllogisms and the particular syllogisms. ('Analyt.' i. 5.)

(26.) But if one thing belongs to the whole of the same thing and another belongs to no part of it, or both to the whole or to no part, such a figure I call the third; and I call that the middle in it of which both the predications are made, and I call the extremes the predicates:—And the middle is placed without the extremes, and last in position—And a syllogism will be possible both when the terms are universal and when not universal with reference to the middle.

Accordingly if they are universal, when both P and R belong to all S, P will belong to some part of R of necessity: for since the affirmative is convertible, S will belong to some part of R, so that since P belongs to all of S, and S to some part of R, of necessity P belongs to some part of R: for the syllogism is produced by means of the first figure.

To form a syllogism universally by means of this figure is not possible, neither in the negative nor in the affirmative. ('Analyt. Pr.,' i. 6.)

(27.) And it is manifest that every demonstration will be by means of three terms and not more. And since this is clear, it is manifest that it consists of two propositions and not more: for the three terms are two propositions. ('Analyt. Pr.,' i. 25.)

(28.) It is necessary in all the figures that the middle be in both the propositions. If then the middle term both predicate and be the subject of predication, or itself predicates and anything is denied of it, it will be the first figure: but if it both predicates and is denied of something, it will be the middle figure: and if other things are predicated of it, or one thing is denied and another predicated, it will be the last figure. ('Analyt. Pr.,' i. 32.)

(29.) Moreover in all syllogisms one of the terms must be affirmative and it must be universal: for without the universal there will either be no syllogism, or it will not relate to the thing proposed, or the very thing to be proved will be assumed. For let it be proposed to prove that music is an honourable pleasure; if then any one should assume that pleasure is honourable without adding the "all," it will not be a syllogism: and if he should assume that some pleasure is excellent, if he means other pleasure, it has nothing to do with the subject proposed, and if he means the very pleasure itself, he assumes the very thing which is to be proved. ('Analyt. Pr.,' i. 24.)

(30.) The science of what a thing is, it is possible to investigate by means of this figure alone (the first). For in the middle figure the syllogism is not affirmative, and (the question) what science is, requires the affirmative: and in the last figure there is a syllogism, but not a universal syllogism, and the question what a thing is, belongs to the universal. ('Analyt. Post.,' i. 14.)

(31.) All who attempt to syllogise from things less credible than the conclusion, manifestly do not syllogise rightly. ('Top.,' viii. 6.)

(32.) From what is true it is not possible to form a false conclusion, but from what is false it is possible to form a true conclusion; not however "why" but "that" the thing is. ('Analyt. Pr.,' ii. 2. Accordingly it is manifest that, if the conclusion be false, of necessity those things are false either wholly or partly from which the argumentation (λόγος) is derived; but when the conclusion is true, it is not a matter of necessity for either anything or all to be true, but it is possible when none of the things in the syllogism are true, for the conclusion to be true notwithstanding, but not as a matter of necessity. And the reason is, that, when two things are so related to one another, that when one is, of necessity the other is, when this other is not, neither will the first be, but when it is, it is not a matter of necessity that the first be. ('Analyt. Pr.,' ii. 4.)

(33.) And a Philosophema is a syllogism demonstrative, and an Epicheirema a syllogism dialectic, and a Sophisma a syllogism contentious, and an Aporema a dialectic syllogism of contradiction. ('Top.,' viii. 11.) Demonstration then is, when from true and first things the syllogism comes, or from things of such a kind which by means of some first and true things have received the beginning of the knowledge concerning them: and a Dialectic syllogism is that syllogism which is derived from common notions. ('Top.,' i. 1.)

And speech is called false in one manner, when it appears to be conclusive but is not conclusive, which is called a contentious syllogism (*ἐριστικὸς συλλογισμός*). ('Top.,' viii. 12.)

Contentious speech is the syllogising from notions that appear to be common notions, but are not; or it is merely apparent syllogising. ('Soph. Elench.,' 2.)

The equality of opposite arguments (*λογισμοί*) would appear to be productive of doubt. ('Top.,' vi. 5.)

(34.) Induction (*ἐπαγωγή*) is the progress from the particular to the universal: thus if a pilot who is skilled is the best, and if a charioteer who is skilled is so, universally also the person who is skilled in each thing is the best. And induction is the more persuasive and more clear, and more intelligible to sense, and in vogue among the many; but the syllogism has more force and is more effective against opponents in argument. ('Top.,' i. 12.)

(35.) Induction then and the syllogism from induction, is through one extreme to syllogise the other with the middle term; for example, if B is the middle term of A and C, by means of C to show that A may be predicated of B: for thus we make inductions.—But C must be considered as composed of all things individually: for induction is made through all. ('Analyt. Pr.,' ii. 23.)

(36.) In a manner induction is opposed to syllogism; for the one (syllogism) by means of the middle term proves the first term to be predicated of the third, but the other (induction), by means of the third term, proves the first to be predicated of the middle term. Naturally then the syllogism through the middle term is prior and more familiar; but to us the syllogism through induction is the clearer. ('Analyt. Pr.,' ii. 23.)

(37.) Probable (*εἰκός*) and Sign (*σημεῖον*) are not the same, but Probable is a proposition conformable to opinion: for what for the most part men know to be produced in a particular way or not produced, or to be or not to be, this is probable; for example, that men hate the envious, or like those who love. And Sign must be considered to be a proposition demonstrative either necessary or conformable to opinion: for if when anything is, the thing is, or when anything has happened, the thing happens before or after, this is a sign of the thing having happened or being.

Enthymema then (*ἐνθύμημα*) is a syllogism from probables or signs. ('Analyt. Pr.,' ii. 27.)

(38.) And an example is, when the first is shown to belong (*ὑπάρχον*) to the middle through one like the third. But it must be known that both the middle belongs to the third and the first to the like. For example, let A be bad, and B be to take up war against neighbours; and C, the Athenians, taking up war against the Thebans; and D, the Thebans, taking up war against the Phocians. If then we wish to show that to make war on the Thebans is a bad thing, we must assume that to make war on neighbours is bad. And the evidence of this is from the like things, for example, that the war of the Thebans against the Phocians is bad. Since then to make war on neighbours is bad, and since the war against the Thebans is against neighbours, it is manifest that to war against the Thebans is bad. Accordingly it is clear that B belongs to C and to D (for both C and D are to take up war against neighbours), and that A belongs to D (for the war of the Thebans against the Phocians was not good); but that A belongs to B will be shown through D.

And in the same manner also if through more like things, the evidence should exist of the middle belonging to the first. Accordingly it is manifest that the example is neither as a part to the whole, nor as a whole to a part, but as a part to a part, when both are included in the same notion, and the one is known. And it differs from induction, inasmuch as induction by means of all the particulars shows that the first belongs to the middle, and does not connect the syllogism with the first, but the example both connects it and does not derive its evidence from all the particulars. ('Analyt. Pr.,' ii. 24.)

(39. Both modes of proof, that by syllogisms and that by induction, teach by means of things known before; the one taking its assumptions from the general notions of mankind, and the other showing the universal through the evidence of the particular. And in the same manner rhetorical arguments persuade; for they (the arguments) are either by means of example, which is induction, or by means of enthymemata, which is syllogism. ('Analyt. Post.,' i. 1.)

(40.) Refutation (*ἔλεγχος*) is a syllogism of contradiction. ('Analyt. Pr.,' ii. 20.)

(41.) And objection (*ἔνστασις*) is a proposition contrary to a proposition. And it differs from the proposition, in as much as it is possible for the objection to be particular, but the proposition either cannot be so at all, or at least not in the universal syllogisms. ('Analyt. Pr.,' ii. 26.)

(42.) Since it is the nature of some things through themselves to be known, and of some through other things (for principles (*ἀρχαί*) are known through themselves, but other things subordinate to principles are known through other things), when any one attempts to show through itself a thing not known through itself, then the thing to be proved (*τὸ ἐξ ἀρχῆς*) is assumed. ('Analyt. Pr.,' ii. 16.)

And people appear to assume what is to be proved in five ways. Most manifestly and first, if a person should assume that which requires to be proved. And this in itself does not easily escape notice; but in common names (*συνώνυμα*),* and in all those things in which the name and the notion (*λόγος*) have the same meaning, it is more easy to escape detection. And the second way is when a person assumes the universal when it is necessary to prove the particular; for example, if a person attempting to show that of contrary things (*ἐνάντια*) there is one science, should universally assume that of opposed things (*ἀντικειμένα*) there is one science; for he appears to assume with many other things that which it was requisite to prove by itself. The third way is, if any one, when the thing proposed is to show the universal should assume the particular; for example, if he had to prove that of all contrary things there is one science, he should assume that there is one science of some particular contrary things; for such a one also appears to assume separately by itself that which it was requisite to prove together with others. Again, if any one should assume the problem (*τὸ προβληθέν*) by dividing it; for example, if, when it was required to show that the art of medicine concerned both health and sickness, he should assume each separately. Or if any one should assume one of two things which follow one another of necessity; for example, that the side (of a square) has no common measure with the diagonal, when it was required to show that the diagonal has no common measure with the side. ('Top.,' viii. 13.)

(43.) The affirmative (demonstration) is prior to the negative, and more easily known, for through the affirmation the negation is known, and the affirmation is prior, as being also is prior to not being. Further, it is nearer to a first principle; for without the positive proof there is no negative proof. ('Analyt. Post.,' i. 25.)

(44.) All persons who form a conclusion through that which is impossible, form indeed a false conclusion, but they show what has to be demonstrated by virtue of an hypothesis, when anything impossible results by the assumption of the contradiction (*ἀντίφασις*) (10). ('Analyt. Pr.,' i. 23.)

The demonstration which leads to an impossibility is thus:—If it were required to show that A does not belong (*ὑπάρχει*) to B, it must be assumed that it does, and that B belongs to C, so that it follows that A belongs to C. But let this (that A belongs to C) be known and agreed to be impossible. Then it is not possible for A to belong to B. If then it is granted that B belongs to C, it is impossible for A to belong to B. And since the affirmative (*κατηγορική*) demonstrative is better than the negative, it is manifest that it is also better than the demonstrative which leads to impossibility. ('Analyt. Post.,' i. 26.)

(45.) The object of science and science differ from the object of opinion and opinion, inasmuch as science is universal and is of necessity, and the necessary can not be otherwise, but opinion is unsettled. ('Analyt. Post.,' i. 33.)

(46.) Induction is not possible when there is no sensuous perception; for sensuous perception belongs to the particular. Nor yet through sense nor through perception is it possible to attain science. For though sensuous perception refers to a thing as being of a certain quality, and not to any definite thing, nevertheless it is necessary to have some one definite thing as the sensuous object, and the where and the when. But what is universal and in all things it is impossible to have sensuous perception of, for it is neither any particular thing nor now; for, if it were, it would not be universal; for we affirm that the always and the everywhere are universal. Wherefore, also, if we were in the moon and saw the earth intercepting (the light of the sun), we should not know the cause of the eclipse; for we should perceive that it is eclipsed now, but we should not know why at all, for there would be no sensuous perception of the universal. ('Analyt. Post.,' i. 18, 31.)

(47.) And I call universal whatever belongs to all both of itself and in itself. It is manifest, then, that whatever is universal of necessity belongs to the things. And the "of itself" and "in itself" are the same; for example, of itself a point belongs to a line inasmuch as it is a line; and to a triangle, inasmuch as it is a triangle, there belong two right angles; for of itself the triangle (as to angles) is equal to two right angles. And the universal then is, when it can be demonstrated of any individual (of the class) and of no class prior to that. ('Analyt. Post.,' i. 4.)

(48.) To what thing anything of itself belongs, that very thing is its own cause (*αἴτιον*); and the universal is first, therefore the universal is the cause. ('Analyt. Post.,' i. 24.)

(49.) Universally, of all things it is impossible for there to be demonstration; for it would proceed indefinitely, so that thus there would be

* See 'Categ.' c. 1, definition of *ὁμώνυμα* and *συνώνυμα*.

no demonstration at all. ('Metaph.,' iv. 4.) And it is not possible for the thought to go through the infinite. ('Analyt. Post.,' i. 22.)

(50.) And those things are true and first which not through other things, but through themselves receive assent; for it is not necessary in scientific first principles for the "wherefore" to be inquired after, but each of the principles must itself of itself receive assent. ('Top.,' i. 1.) And in two ways it is necessary first to know: for as to some things it is necessary first to admit that they are; but as to others it is necessary to understand what the thing spoken of is; and as to others again both; for example, in the proposition that either to affirm or deny everything is true, we must assume the "is"; and in the triangle, that it signifies this particular thing; and in the monad both, both what it means and that it is. ('Analyt. Post.,' i. 1.)

(51.) But we assert that all science is not demonstrative, but that that of the immediate (ἄμεσα) is incapable of demonstration. And that this is a matter of necessity, is clear; for if it is necessary to understand the prior and those things from which the demonstration comes, and the immediate at any time enter into the demonstration, it is a matter of necessity that the immediate are not capable of demonstration. And this then we so affirm, and that there is not only science, but also some first principle (ἀρχή) of science by which we know the terms (ὅροι). It is necessary not only to know first the first things, either all or some, but also to know them more: for always that through which each thing is, is more (in a higher degree); for example, that through which we love, is more love. So that if we know by the first things and believe, those things also we know and believe more, since by them we know also the things which come after. ('Analyt. Post.,' i. 3. 2.)

(52.) And an immediate proposition (πρότασις ἄμεσος) is a beginning (ἀρχή) of demonstration, and an immediate proposition is that to which there is no prior proposition. ('Analyt. Post.,' i. 2.)

(53.) And of an immediate syllogistic beginning I call that the Thesis which need not be demonstrated, and which it is not necessary that he who is going to learn anything should possess; but what he who is going to learn anything must necessarily possess, is an axiom (ἀξίωμα). ('Analyt. Post.,' i. 2.)

(54.) The first things will be definitions (ὁρισμοί) incapable of demonstration. For definition is of what the thing is and of essence; but all demonstrations appear to go by hypothesis and to assume what a thing is; for example, mathematical demonstrations take for granted what a unit is and what odd is, and other kinds of demonstration in like manner.

The definition is a certain notification (γνωρισμός) of essence. ('Analyt. Post.,' ii. 3.)

(55.) He who defines shows either what a thing is or what the name means. ('Analyt. Post.,' ii. 7.)

All who in any way by a name give an account of a thing, manifestly do not give the definition of the thing, since every definition is speech (λόγος). ('Top.,' i. 3.)

What a triangle means, the geometer assumes; but that it is, he proves. ('Analyt. Post.,' ii. 7.)

(56.) And it is necessary to investigate, when considering things which are alike and do not differ, in the first place what they all have in common, then again with respect to other things what things they have which are of the same genus as the former, and are the same as one another in species, but different from the first named. And when in these things it has been found what they all have in common, and in the other things in like manner, we must consider again if there is anything in common in these things which have been taken, until you come to one notion (λόγος); for this will be a definition of the thing. But if a man does not come to one notion, but to two or more, it is manifest that what is sought cannot be one, but more than one. For example, if we should inquire what magnanimity is, we must consider in the case of some magnanimous persons whom we know, what one thing they all have by which they are such. For example, if Alcibiades is magnanimous, or Achilles, and Ajax, what one thing they have all in common? Non-endurance of insult; for the first made war, and the second was enraged, and the third killed himself.

Again in the case of others, such as Lysander or Socrates; if indifference in prosperity and adversity are the things that they have in common, these two things I take and consider what same things are contained in the absence of all feeling (ἀπαθεία) as to fortune, and non-endurance of insult. If they have nothing in common, there must be two species (εἴδη) of magnanimity. ('Analyt. Post.,' ii. 13.)

(57.) Of the things indeed which are in the definition, each will extend further, but all will not extend further. For of necessity there must be this essence (οὐσία) of the thing: for example, there is number in every Three (τριάς), odd (περιττόν), and the prime in both ways, both so as not to be measured by any number and not to be composed of numbers. This then is Three, number odd, and prime, and prime in this manner: for of each of these things some are in all odd numbers also, but the last is in Two also, but all are in none. ('Analyt. Post.,' ii. 13.)

(58.) And it is necessary, when a person is labouring at any whole thing, to divide the genus (γένος) into things indivisible in species, the first; for example, to divide number into Three and Two. ('Analyt. Post.,' ii. 13.)

All genus is divided by differences which are opposed to one another in division, as a living animal by the difference of quadruped and bird and fish. ('Top.,' vi. 6.)

That everything should fall under the division, if they be things opposed in which there is no middle, is not an assumption, for it is necessary that everything should be in one of them, if there shall be a difference (διαφορά) in it (the genus). ('Analyt. Post.,' ii. 13.)

It is requisite, moreover, to divide by privation (στέρησις), and those who cut into two parts divide by privation. And there is no difference in privation, so far as it is privation, for it is impossible that there should be species of a thing which does not exist; for example, of animals without feet or animals without wings, as there is in the case of winged animals and quadrupeds. ('De Partib. Animal.,' i. 3.)

(59.) Definition (ὁρίσμος) consists of genus and differences (διαφορῶν). ('Top.,' i. 8.)

It is requisite that he who defines well define through genus and differences, and these belong to those things which are plainly clearer than and prior to the species (εἶδος).

And there are three ways in which the definition is not from prior things. The first is, if through what is opposed that which is opposed is defined; for example, if through evil good is defined; for the opposed exist by nature. But to some the knowledge of each of them appears to be also the same, so that neither is one better known than the other. But it should not escape notice that some things perhaps it is not possible to define otherwise; for example, the double without the half, and all those things which of themselves are said in relation to anything (πρός τι): for in all such things to be is the same thing as to be related to something in some manner, so that it is impossible without the one to know the other; wherefore it is necessary in the notion (λόγος) of the one that the other also be included.

Another way is, if a man uses the very thing which is defined. But this escapes notice when he has not used the name itself of the thing defined: for example, if he defined the sun to be a star which appears in the day-time; for he who employs the word day employs the word sun. And it is requisite, in order that such errors may be detected, to exchange the name (ὄνομα) for the notion (full speech, λόγος): for example, that day is the passage of the sun above the earth; for it is manifest that he who has spoken of the passage of the sun above the earth has spoken of the sun. So that he who has employed the word day has employed the word sun. A third way is, if that which is opposed in division is defined by that which is opposed in division; for example, that odd is greater than even by a unit. For things of the same genus opposed in division exist by nature, and odd and even are opposed in division; for both are differences of number. ('Top.,' vi. 4.)

(60.) To know what a thing is, is the same as to know why it is. What is an eclipse? Privation of light from the moon through the earth intercepting (the light). What causes an eclipse? or why is the moon eclipsed? Because the light fails, owing to the interposition of the earth. What is symphony? A proportion (λόγος) of numbers in sounds high or deep (ὀξύ, βαρύ). Why is the high symphonious with the deep? Because the high and deep sounds have a proportion (λόγος) of numbers. ('Analyt. Post.,' ii. 2.)

(61.) We seek the cause after we know that a thing is; but sometimes they are manifest at the same time also; but it is not possible to know the cause before we know that the thing exists. ('Analyt. Post.,' ii. 8.) For it is impossible to know what a thing is when we are in ignorance whether it exists or not.

And both the notion or expression (λόγος) appears to give evidence to phænomena, and phænomena to the notion. ('De Coel.,' i. 3.)

(62.) The cause is the middle (μέσον), and in all things this is sought. ('Analyt. Post.,' ii. 2.)

(63.) Not only that a thing "is" ought the definition (ὁριστικός λόγος) to show, as the most part of definitions declare, but the cause also ought to be in it, and to be clear. But the notions of the definitions are as conclusions: for example, what is quadrature? It is a rectangular equilateral figure being equal to a figure of unequal sides.* And such a definition is an expression of the conclusion. But the definition which says that quadrature is invention of a middle, states the cause of the thing. ('De Animal.,' ii. 2, § 1.)

(64.) And it appears that not only what a thing is, is useful towards knowing the causes of the accidents of essences (τῶν συμβεβηκότων ταῖς οὐσίαις), as in mathematics what a straight line is and what a curved line is, or what a line and a plane are, is useful towards seeing how many right angles the angles of a triangle are equal to; but conversely also the accidents help in a great degree to perceiving what the thing is; for when we are able by the appearance (φαντασία) to give an account of the accidents either of all or of the greater part, then concerning the essence also we shall be able best to speak; for of all demonstration what a thing is (τὸ τί ἐστιν), is the beginning. So that in all definitions in which it does not happen that we can recognise the accidents, and cannot even form a conjecture of them easily, it is manifest that they are all enunciated dialectically (διαλεκτικῶς) and emptily (κενῶς). ('De Animal.,' i. 1, § 8.)

(65.) And of some things some other thing is the cause, and of other things not.

Accordingly it is manifest that of those also which belong to the class of what a thing "is," some are immediate (ἄμεσα) and first principles (ἀρχαί), which we must assume (ὑποθέσθαι) both to be, and we must assume what they are, or in some other way make clear, which the arithmetician does; for both what unity is and that it is he assumes. But as to those things which have a middle (μέσον), and of which something else is the cause of the essence, we can, as we have said, show by demonstration. ('Analyt. Post.,' ii. 9.)

---

* This is what the 14th Proposition of the Second Book of Euclid shows.

(66.) And of proposition (putting, placing, θέσις) that which takes for granted either of the parts of the enunciation, for example, that a thing is, or is not, is Hypothesis (ὑπόθεσις): but the proposition without this is Definition; for the definition is proposition (θέσις); for the arithmetician lays down (puts, places, τίθεται) that the unit is indivisible, as far as quantity is concerned: but it is not hypothesis; for what a unit is and that there is a unit is not the same thing. ('Analyt. Post.,' i. 2.)

(67.) All demonstrative science is about three things, two of which are assumed to be; and these two are genus, the affections (παθήματα) of which by themselves it contemplates, and what are called common axioms (ἀξίωματα) from which first principles science demonstrates; and thirdly, the affections (πάθη) of which what each means it takes for granted. ('Analyt. Post.' i. 10.)

(68.) It is clear that it is not possible to demonstrate the peculiar first principles of each thing: for those first principles will be the first principles of all things, and knowledge of those is that which is supreme over all. For he knows more who knows from the higher causes: for he knows from the prior when he knows from causes which depend not on other causes. So that if he knows more and most, that science also will be both more and most. ('Analyt. Post.' i. 9.)

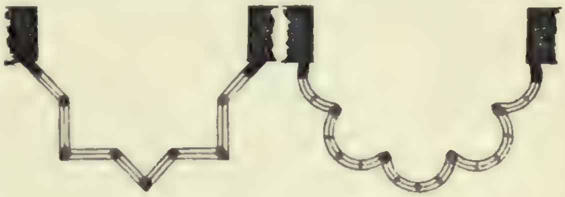
(69.) Accordingly that it is impossible to have science from demonstration, if a man does not know the first principles which admit of no middle (ἀρχαὶ αἱ ἄμεσαι), has been said before. But as to the knowledge of things which want a middle, a man may be in doubt. All animals have an innate discerning faculty, which men call perception (αἴσθησις). And as they have perception, in some animals there is a permanence (μονή) of the thing perceived (αἴσθημα); and in others there is not. In those animals, then, in which it is not, there is either wholly, or with respect to things of which there is no permanence in them, no knowledge except of what they perceive: but in those animals in which there is, there is the faculty of having the perception in the mind, though they do not then perceive. And many animals being such, there results a difference among them, so that some have reason owing to the permanence of such things, and some have not. Accordingly from perception comes memory (μνήμη), as we call it, and from the frequent remembrance of the same thing comes experience (ἐμπειρία): for many remembrances in number are one experience. And from experience, or from a whole thing remaining tranquil in the mind as one thing apart from the many, whatever thing in all these things is as one and the same thing, is the beginning of art and of science; if about production (γένεσις), of art; if about that which is or being (τὸ ὄν), of science. Neither indeed do the faculties (ἕξεις) exist in the mind separate, nor do they proceed from other faculties which are more intelligent, but they proceed from perception; as in battle when a flight has taken place, when one stops, another stops, and then another, until order is restored: and the mind exists in such a manner as to have the faculty of being so affected. For when one thing of things which are not different stands, it first of all is in the mind as universal (for the mind perceives the individual, but the perception belongs to the universal, for example, it belongs to mankind, but not to a man ('Callias')): and again it abides in these until the undivided and the universal have abided: for example, such or such an animal abides, until animal generally abides; and in this in like manner. It is manifest then that it is necessary for us to know the first things by induction: for perception also in this manner produces the universal in the mind.

And since of the faculties that concern the understanding (διάνοια), by which we learn the truth, some are always true, and some admit of falsehood, as opinion and reasoning (λόγισμος); and since science and intellect (ἐπιστήμη καὶ νοῦς) are always true, and there is no other kind of science more exact than intellect, and since the first principles are clearer than the demonstrations, and since all science is together with reason (λόγος),* there can be no science of the first principles: and since nothing can be truer than science except intellect, intellect must be intellect of first principles: and this appears both from considering these things, and that the beginning of demonstration is not demonstration, so that neither is science the beginning of science. If then we have no kind of truth which exists independent of science, intellect (νοῦς) must be the beginning of science. ('Analyt. Post.' ii. 19.)

ORICHALCUM or ARICHALCUM. [BRASS.]

ORIEL. The origin of this term is uncertain; its use is, however, thoroughly established, and the meaning now affixed to it is sufficiently clear and precise. It is applied to that particular kind of bay-window which is made to project from the upper story of a building. The distinction therefore between a bay and an oriel is this: by a *Bay* is understood a projecting window, or rather a projection pierced with window openings in its entire width, and rising immediately from the ground, whether it be confined to the lower part of the building or carried up through one or more stories above the ground floor; by an *Oriel*, is understood a bay which does not descend to the ground, but is suspended over the face of the wall beneath it. Oriel accordingly corresponds with the German terms *Erker-fenster* and *Chor-fenster*, which are almost the only ones of similar import in any foreign language. This absence of a name for it is accounted for by the thing itself being little known in the architecture of other countries, and in our own it occurs only in our Domestic Tudor, such form of window being very rare indeed in ecclesiastical structures. In our domestic, which also comprises collegiate, architecture, it is a beautiful and valuable feature, and one which admits of very great diversity of design, and imparts much variety and liveliness of effect to a building, more especially if there be ground-bays likewise, the two kinds of projection both harmonising and contrasting with each other. The colleges of Oxford and Cambridge afford numerous excellent examples of both bays and oriels.

Internally there is no distinction between bays and oriels, inasmuch as both the one and the other form a recess whose sides are filled with windows. But greater variety of plan occurs in oriels than in bays, which are usually more spacious as to breadth, and of shallower proportions as to depth; they are also either rectangular in plan, or form three sides of an octagon, whether a regular one or not; whereas curved forms are of frequent occurrence in the plans of oriels, and are occasionally combined with straight ones. Yet as similar plans do occur in bays, no real distinction can be founded upon such accidents of design. Thornbury Castle, Gloucestershire, contains an example of a bay of very unusual character, both in respect to plan and elevation, its plan in the upper part being different from that of the lower, and in some degree projecting over it, as is indicated in the annexed figures, the first of which describes the plan of the lower, the other of the upper floor.



Bays generally terminate in either a plain or embattled parapet; but oriels are for the most part made to show some sort of roof, either rising behind or resting upon the mouldings which serve as their cornice. Occasionally this roof or *crown* is rendered an ornamental part of the design, and terminated by some kind of finish. Oriels may therefore be described as consisting of three distinct parts, namely, the supporting portion, consisting of a series of mouldings, splayed off so as to come down to a point below, somewhat after the manner of a corbel (for which member we would accordingly suggest *corbel-stool* or *corbel-base* as a significant and very convenient term); 2ndly, the body of the oriel, consisting of the *window-apron* or window-parapet, and the window-openings themselves, the former of which is almost invariably panelled so as to correspond with the lights, whereby the whole is made to consist of a series of panels, those in the lower range being blank or solid, the others perforated and glazed; 3rdly, the *crown* or roofing, occasionally including under that term the ornamental finish, of whatever kind it may be, above the windows, when that happens to form a conspicuous termination to the design, as is the case with the semicircular oriel at Great Chalfield, where the parapet is formed by a rich bandeau or crown of strawberry-leaf ornaments or *Tudor-flowers* with open work between them.

ORIFLAMME. [BANNER.]

ORILLON, is the term applied in fortification to the projecting tower placed at the shoulder angle of the bastion. [See M in the plate to BASTION.] This orillon covers the flank from view from the front; it is frequently found in old fortresses and also in Coehorn's system of fortification.

ORI'ON (Constellation). We have already noted the appearance which the Greek astro-mythological system has of being an application of existing fables to a subdivision of the stars derived from the East, mixed perhaps with the Oriental allegories, imperfectly understood. The trivial character of the myths by which the Great Bear and Orion, perhaps the two most remarkable constellations in the heavens, are accompanied, is enough of itself to upset any claim to high antiquity for the system above noted. We owe this brilliant cluster, according to Hyginus (of whose two or three very slight stories this is the most striking), to the fraternal solicitude of Apollo that his sister Diana should remain unmarried, or at least that she should not marry one Orion, a son of Neptune according to some, or of a rather curious parentage according to others. The deity above mentioned, when persuasion had failed, hit upon a method of preventing his sister's match, as follows. He asserted that she could not hit a black object which appeared in the sea at a distance; and she, being a good markswoman, showed him immediately that she could. This black object, however, was the head of her lover, who was swimming at the time, and the end of it was, that, according to custom, he was immediately gazetted as a constellation, with his club and lion's skin.

---

* The word λόγος is rendered 'ratio' by the Latin translation. Trendelenburg translates the passage thus:—"jede wissenschaft aber mit einem grunde verknüpft ist." Perhaps λόγος may be understood as in No. 2. Λογισμὸς should be related to λόγος as ὁρισμὸς (defining, terming) is to ὅρος (finis, term).

Orion is surrounded by Eridanus, Canis Major, Gemini, Auriga, and Taurus. The position of his belt, with respect to Aldebaran, and Sirius, and the proximity of Procyon, Castor and Pollux, the Pleiades, &c., render it difficult to forget and unnecessary to describe this part of the heavens. The list of stars is as follows: α and β, of the first magnitude, were frequently called Betelguese or Betelgeux, and Rigel, corruptions from Arabic names; γ was called Bellatrix.

Character.	No. in Catalogue of Flamsteed, (Bradley).	No. in Catalogue of British Association.	Magnitude.
π^{1} *	1	1486	4
π^{2}	2	1491	4
π^{3}	3	1495	4
β	19	1623	1
γ	24	1687	2
η	28	1684	3
δ	34	1730	2
λ	39	1749	4
ι	44	1762	4
ε	46	1765	2
σ	48	1780	4
ζ	50	1794	2
κ	53	1843	3

ORMUZD. [ABIMANES.]

OROGRAPHY, or **OROLOGY**, from ὄρος a mountain, and γραφή description, and λόγος, discourse, respectively, (*the science of mountains*,) belongs technically to three branches of natural knowledge, physical geography, meteorology, and geology; but it is usually regarded as a part of the first, and confined to the subjects of the configuration, magnitude, and distribution of mountains, with some general reference, also, to their climate, and to their relations to organic nature.

Though the term mountain be universally understood, yet it will be found very difficult to define strictly what is meant by it. From the mole-hill in the meadow, to the gigantic Himalayas, the gradations are infinite, and no positive line can be drawn between the hill and the mountain. Moreover, the name is sometimes given to a single elevation or peak, as Mount Ætna, &c., and sometimes to a whole and extensive cluster of eminences, as Mount Caucasus. Isolated mountains are rare, and when they do exist are generally, though not always, volcanic.

The general disposition of mountains is in groups or chains. The word group explains itself, but what is understood by a chain may not be so clear. When hills or mountains are so arranged as to form a line or band whose length greatly exceeds its breadth, such a disposition, whether the line be straight or curved, is called a chain, and sometimes a ridge; though the latter name is more exclusively applied to the lesser chains. We are not however to understand by a chain of mountains, a single unbroken longitudinal eminence, like that formed by the connected roofs of a row of houses. A chain of mountains, on the contrary, is very irregular, and composed of many subordinate parts. In what is regarded by some geographers as a complete chain there are three parallel or nearly parallel ridges; the centre one is usually the highest. These three ridges, though distinct, are seldom equidistant from each other, and they are frequently united. From the points of junction, and from different parts of the outer ridges, other chains strike off at various angles, and these in turn send off other ramifications, which go on dividing and diminishing in height till the last undulations are lost in the general surface of the plain. These different branches of a chain have received various and very arbitrary names. Some divide the whole system of a chain into the primary, principal, primordial, or great chain, and secondary and tertiary chains; but these names having now reference to the order of formation of rocks rather than to their disposition, though the latter circumstance is greatly dependent on the former, they are at present confined to geological considerations, and we therefore say such a chain or ridge is a branch of some other chain or ridge. Thus the Apennines are a branch of the Alps. Minor ramifications, when short, are called spurs. Wherever the main chain sends off other chains, the former is, at that particular spot, higher than elsewhere, so that between two consecutive elevations there is an apparent depression: hence the summit or ridge-line of the main chain is divided into heights, which are called peaks, domes, &c., according to their shape; and depressions, which receive the general name of passes, because they are the places where the passage over the chain from opposite valleys is most easily effected. These passages or passes are termed *cols* in the Alps, *ports* in the Pyrenees, and *pertuis* in the Jura. They are also called gorges or defiles, but incorrectly, for the gorge is properly the contracted part of a valley, and the defile, a very narrow passage at the foot of the mountains or winding amongst them. The ridge-line of great chains is also irregular in breadth as well as height; it is sometimes very narrow and sometimes very broad, and in some places spreads out into what is termed table-land (Langfield in Norway). Table-lands, or plateaus, are however not always of this terrace form: they are not unfrequently sunk, if we may so say, into the broad summit of the ridge, so as to be surrounded by lofty eminences and peaks. Table-land is also sometimes ascended by gentle acclivities, without any appearance of mountains.

The valleys which are situated between the parallel ridges of the main chain are termed longitudinal valleys; their axis, and consequently the principal watercourse, is nearly parallel to the direction of the chain. The valley of the Rhône above the lake of Geneva, the valley of the Magdalena in South America, &c., may be taken as examples. Two things have been remarked in longitudinal valleys; first, that there is sometimes so perfect a conformity between the re-entering angles on one side and the salient angles on the other, that if it were possible to bring the two sides into contact, they would perfectly correspond, so as to leave no trace of their having been separated; and, secondly, it has been observed, that the side of the valley opposite to the centre ridge is the steepest. These observations are true as regards many places, but are by no means to be received as universally correct. The other valleys, whose axes form various angles with the direction of the great chain, are the principal valleys of a country, and are usually designated by the names of the chief rivers which flow through them. The valleys of the tributary streams which empty themselves into the main rivers are called lateral valleys. The terms upper and lower valley are sometimes used to denote the parts of a valley as they lie along the higher or lower part of a river's course. Such then are the parts of a regular chain of mountains, but we are not to suppose that all those great elevations to which we give the name of chain are thus regularly formed. Mountains are sometimes grouped, as we have said, so as to present no appearance of a chain; sometimes the chains run parallel, but wholly independent of each other; in some cases they radiate from a common centre or nucleus. Indeed nothing can be well more irregular than the arrangement of mountains, and they differ as much in height, steepness, and particular appearance. By some (Bergmann) it has been imagined that in chains running north and south the western slope is the most abrupt, and that when the chain runs east and west the southern slope is the steepest. But this is far from being always the case, and General Andreossy has laid down as a principle that the steep side of a chain of mountains is that which looks towards the higher part of the general slope on which the chain is set. This opinion is doubtless better founded than that of Bergmann, nevertheless it is not strictly correct; and there seems reason to believe that no general law obtains on this subject.

The appearance presented by chains of mountains is not only very different in different parts, but the very same mountains when seen at a distance no way resemble their aspect when seen nearer. At a distance the minute irregularities are lost in the general contour, and the particular shadows are blended into a uniform tint. The forms of rocks generally depend on their nature, and a practised eye can sometimes pretty correctly divine the latter from the former. These may either present the aspect of needles or sharp pointed masses, or the summits may be dome-shaped, or stretch along like a vertical wall, either entire or bearing a resemblance to ruined battlements and towers; sometimes the whole mass is piled up into a succession of gigantic steps or terraces. Individual mountains and hills also vary in form; those which are volcanic are generally conical; others are round, oval, lumpy, saddle-backed, &c.

Mountain-chains are the natural water-sheds (the *divortia aquarum*), but it must not be thence inferred, as has too frequently been the case, that all water-sheds are mountain-chains. This erroneous idea has covered our older maps with mountains where in nature not a hill is to be seen.

Another error is to regard the mountains of the earth as so many connected chains, which, by starting from some particular point, may be traced stretching and branching continuously over the whole surface of the globe. The fallacy of such pretended continuity is evident from the difference in the arrangement as described by different writers. The truth is, that mountains are scattered over the surface of the land in the greatest confusion, here isolated, there in groups or in chains; the chains being in some places single and independent, in others connected; in one place running in parallel directions, in another intersecting, crossing, or branching off at different angles; in some cases completely enclosing a certain extent of country so as to form an entire and perfect basin, in others only partially enclosing a space. In one country the mountains are set in the centre, or near one of its coasts, and in the direction of the greatest length of the country; in another, they are set across the country. In fact, the chains are observed to be in all possible directions, both as regards the points of the compass and the trending of the coast-lines. Thus with the exception of the Andes and the Rocky Mountains, the Appalachians, the Ghauts of India, the coast-mountains of Abyssinia, the Scandinavian Alps, and the Apennines, there is very little conformity between the direction of mountain-chains and the configuration of countries.

Mountains have a very important part to perform in the general economy of the earth; they arrest the fleeting clouds, whose precipitated waters they store up in their interior and exhaustless reservoirs, whence springs are continually issuing, which unite and form those streams that fertilise the plains, or, collected into mighty rivers, favour the transport of commodities and facilitate the intercourse between the ocean and the interior of the continents. The influence of mountains on local climate is all-powerful, and depends upon the direction in which they lie as regards the sun's course, their height, their position on the surface of the globe, their proximity to or remoteness from the sea, the winds they arrest or give passage to, &c. Mountains have moreover a climate of their own, or rather a great variety of climates. Thus, in ascending from the sea towards the summit of the Andes, almost every kind of climate is passed through, nearly as completely as if the traveller were to proceed from the equator towards the pole. At an elevation of about 16,000 feet on the Andes under the equator, we reach the lower limit of perpetual congelation; and mountains in that region which exceed that height have their summits covered with eternal snow. The line of perpetual congelation is, however, far from being parallel with the general surface of the earth. It approaches that surface as it advances towards the poles, but the laws which determine this line are still imperfectly known. [Climate; Snow, Perennial.]

---

* π^{1}, π^{2}, π^{3}, of Bayer are *g*, π^{1}, and *r* in modern catalogues.

The limits of perpetual congelation, as ascertained from the stability of snow on the mountains, are subject to vary with the particular aspect of the mountains and other local circumstances. Thus, generally speaking, the snow-line is highest on the south side of mountains in the northern hemisphere, and *vice versâ*; but this is not always the case; and the line of perpetual snow is much higher on the northern than on the southern side of the Himalaya mountains. Mr. Pentland states that the limit of perpetual snow is at an elevation of 15,800 feet on the mountains of Vilcanota in South America, which are as far south as 14° 33′.

The fact of the cold increasing as we ascend mountains is due in part to the greater rarity of the atmosphere in the higher regions, and to their greater distance from the radiated heat of the plains; nevertheless the particular aspect of various parts of mountains as regards the sun, and the conformation of the higher valleys, greatly modify the cold of particular places; and a much greater heat is sometimes experienced in a high valley than is felt in one much lower down. To this circumstance is due in part the seeming anomalies that are met with in the habitation of plants, many being found at heights where they would be little expected.

Though mountains are such striking objects, and, when contemplated only with respect to their absolute elevation above the sea, appear to be enormous protuberances on the earth's surface, they are very inconsiderable when compared with the whole mass of the globe. The habitable parts of the earth, at least those where population is most dense, and in which human industry is most concentrated, all lie within a few hundred feet above the sea, which may be regarded as a part of the true surface of the sphere. But even the height of the loftiest mountains, which is about five miles, is only about one eight-hundredth part of the radius of the earth. In books of travels we often find the distance mentioned at which a particular mountain is visible. As assertions of this kind are sometimes loosely made, the following rule will serve for roughly estimating the distance at which a mountain of known height can be seen from the surface of the sphere: multiply the square root of the height of the mountain in feet by 1·2247; the product will be the distance in miles at which the mountain is visible.

With regard to the heights of mountains it may be observed that they vary considerably. Some authors, however, regard every eminence below 1000 feet as a hill. Since the application of the barometer to the admeasurement of heights, there are few mountains of any importance, in Europe at least, whose elevation above the sea is not now known and registered. A list of the principal mountain heights on the globe would fill a volume. It may be sufficient here to give the heights of the principal peaks of some of the more important chains.

Europe.—Mont Blanc, highest point of the Alps, and of Europe, 15,744 feet; Mont Perdu, Pyrenees, 10,994; Monte Corno, Apennines, 9523; Lomnitz, Carpathians, 8799; Sneehetta, Dovrefield, Norway, 8122; Mulhacen, Sierra Nevada, Spain, 11,483; Puy de Sanci, Auvergne, France, 6200; Mont Mezin, Cevennes, France, 5795; Ætna, Sicily, 10,870; Olympus, Greece, 9754; Vesuvius, 3947.

British Islands.—The greater number of the heights about to be stated, are derived from a table of the 'Altitudes above the mean level of the sea of the stations composing the principal Triangulation' of the Ordnance Trigonometrical Survey of Great Britain and Ireland, given in the account of that triangulation recently produced by Captain A. R. Clarke, R.E., under the direction of Colonel Sir Henry James, R.E., F.R.S., Superintendent of the Survey, London, 1858. The altitudes of a few stations but little elevated above the sea, are included for comparison. Fractions of a foot are either omitted, or reckoned as an entire foot, except in heights below 1000 feet, in which they are given.

England.—Sea Fell, highest point in England, 3229; Helvellyn, 3055; Skiddaw, 3038; Cross Fell, 2928; Cheviot, 2669; Coniston Fell, 2575; Ingleborough, 2373; Great Whernside, 2310; Malvern, 1396; Mendip, 979·2; Inkpen Beacon, the loftiest summit of the chalk formation, 972·3; Leith Hill, 967; Fairlight Down, 583·7; Beachy Head, 532·4; Lundy Island, 466; St. Paul's Cathedral, top of cross, 417·9; Severndroog Castle, Shooter's Hill, ground, 406·4; Epping Poorhouse, 371·2; Greenwich Observatory, vane, 214; Ordnance Map Office, Southampton, 78; York Minster, ground, 58; Ely Minster, ground, 51·6; Norwich Cathedral spire, ground, 19·7.

Wales.—Snowdon, highest point in the principality, 3590; Carn Llewellen, 3471; Cader Idris, 2959; Great Orme's Head, 683·1.

Scotland.—Ben Nevis, highest point in the British Isles, 4406; Ben Macdui, 4296; Ben Lawers, 3984; Ben Lomond, 3192; Schehallien, 3564; Ben More, Mull, 3185; Ben More, South Uist, 2034.

Ireland.—Carran Tual, Kerry, highest point in Ireland (?), 3412, doubtful; Slieve Donard, 2788; Nephin, 2638; Mourne Mountains, 2493, doubtful; Howth, 555.

Asia.—Mount Everest, Nepaul, 29,002 (highest mountain known, measured by Colonel Waugh); Kunchin-junga, Sikkim, W. part, 28,178, E. peak, 27,826; Dhawalagiri, Nepaul, 26,862; Juwahir, 25,670. These are peaks of the Himalaya. Ophir, Sumatra, 13,840; Mowna Roa, Sandwich Islands, 13,760; Egmont, New Zealand, 8840; Italitskoï, Altaian chain, 10,735; Ararat, Armenia, 17,212; Arjish, Anatolia, 10,000?; Olympus, Anatolia, 6500; Lebanon, Palestine, 9517; Awatska, a volcano in Kamtchatka, 12,000 feet.

Africa.—Kilimandjaro, lat. 4°·0′ S. in the true Mountains of the Moon, 20,000?; Abba Jarat, Abyssinia, 15,008; Geesh, in Abyssinia, 15,000?; Peak of Teyde, Teneriffe, a volcano, 12,205; highest peak of Atlas chain, 12,000, and perhaps more; Table Mountain, 3816.

America.—Aconcagua, Chile, (highest point in America?) 23,910; Illimani (the richest gold mountain of Peru), 21,140; Chimboraço, Andes, 21,424; Antisana, 19,136; Cotopaxi, 18,775; Pichincha, 15,931; Popocatepetl, Mexico, 17,720: the last four are volcanoes. Mount St. Elias, U.S., 17,850; Fremont's Peak, Rocky Mountains, 13,570; Mount Washington, Appalachians, 6428.

Mount Terror, 13,384; Mount Erebus, 12,367; both in the antarctic lands.

The particular history of important ranges of mountains, as Alps, Altai, &c., will be found in Geog. Div. under their names, respectively, or under those of the countries to which they belong.

OROSELONE. [Athamantin.]

O'RPHICA, certain works falsely ascribed to Orpheus, which embodied the opinions of a class of persons whom Müller thus describes: "These were the followers of Orpheus (*οἱ Ὀρφικοί*); that is to say, associations of persons who, under the guidance of the ancient mystical poet Orpheus, dedicated themselves to the worship of Bacchus, in which they hoped to find satisfaction for an ardent longing after the soothing and elevating influences of religion. The Dionysus, to whose worship these Orphic and Bacchic rites (*τὰ Ὀρφικὰ καλεόμενα καὶ Βακχικά*, Herod., ii. 81) were annexed, was the Chthonian deity Dionysus Zagreus, closely connected with Demeter and Cora, who was the personified expression, not only of the most rapturous pleasure, but also of a deep sorrow for the miseries of human life. The Orphic legends and poems related in great part to this Dionysus, who was combined, as an infernal deity, with Hades (a doctrine given by the philosopher Heraclitus as the opinion of a particular sect); and upon whom the Orphic theologers founded their hopes of the purification and ultimate immortality of the soul. But their mode of celebrating this worship was very different from the popular rites of Bacchus. The Orphic worshippers of Bacchus did not indulge in unrestrained pleasure and frantic enthusiasm, but rather aimed at an ascetic purity of life and manners. The followers of Orpheus, when they had tasted the mystic sacrificial feast of raw flesh torn from the ox of Dionysus (*ὠμοφαγία*), partook of no other animal food. They wore white linen garments, like Oriental and Egyptian priests, from whom, as Herodotus remarks, much may have been borrowed in the ritual of the Orphic worship." ('History of the Literature of Greece,' where the reader will find a full account of the Orphic theology.)

Of the Orphic writers the most celebrated are Onomacritus, who lived under Pisistratus and his sons, and Cercops, a Pythagorean, who lived about B.C. 504. Works ascribed to Orpheus were extant at a very early period. Plato mentions several kinds of Orphic poems; but he intimates that they were not genuine. Aristotle speaks of them as the *so-called* Orphic poems (*τὰ καλούμενα*). In later times all manner of works on mysteries and religion were ascribed to Orpheus. There are also Orphic poems later than the Christian era, which are difficult to be distinguished from those of earlier times. In Fabricius's 'Bibliotheca Græca,' there is a list of the writings ascribed to Orpheus. [Orpheus, in Biog. Div.]

ORPIMENT. [Arsenic.]

ORRERY. There are four planetary machines to which distinct names have been given, corresponding to the phenomena they are intended to exhibit, and which, when combined so as to derive their motions from a common origin, constitute what is now generally understood by an orrery. These machines are the *Planetarium*, the *Tellurian*, the *Lunarian*, and the *Satellite machine*. The planetarium is a mechanical representation of the orbital motions of the planets about the sun, either in circles or ellipses, and with angular velocities either uniform or variable, according to the quality of the instrument. The tellurian and lunarian, when connected in their improved form, exhibit the motion of the moon about the earth and that of the earth about the sun, and the principal phenomena which accompany the changes in their relative positions, such as the succession of day and night and the variable length of both according to the season of the year, the eclipses of the sun and moon, the variations in the moon's latitude, velocity, and distance from the earth, the progressive motion of her apogee, and the retrogradation of her nodes, &c. The satellite machine is chiefly intended to represent the motions of Jupiter's satellites about their primary, combined with the motions of the latter about the sun.

The origin of the term "orrery" is thus given by Mr. Desaguliers, in his 'Course of Experimental Philosophy,' 4to, London, 1734, i., p. 431. After stating his belief that Mr. George Graham, about the year 1700, first invented a movement for exhibiting the motion of the earth about the sun at the same time that the moon revolved round the earth, he remarks, "This machine being in the hands of an instrument-maker to be sent with some of his own instruments to Prince Eugene, he copied it, and made the first for the late Earl of Orrery, and then several others with additions of his own. Sir Richard Steele, who knew nothing of Mr. Graham's machine, in one of his lucubrations, thinking to do justice to the first encourager, as well as to the inventor, of such a curious instrument, called it an *orrery*, and gave Mr. J. Rowley the praise due to Mr. Graham."

In the latter part of the 17th century Huyghens and Roemer employed themselves in the construction of planetary machines in conformity with the Copernican doctrine. The one invented by Huyghens, who first introduced a systematic method of calculating with precision the necessary wheel-work for these machines, received from its author the name of *the Automaton*. It derived its motion from a spring regulated by a balance, the pendulum not having been then introduced as a regulating agent, and served for many years as a pattern in the construction of orreries, as did the instrument of Roemer, called by him a *Planetarium*, in the construction of machines intended chiefly to exhibit the orbital motions of the planets. Roemer had also invented a *satellite machine* prior to the year 1679, the original or a copy of which was presented by him in that year to the English astronomer Flamsteed. Both his machines are described in his 'Basis Astronomiæ,' printed in 1735. We may also mention the *Planetarium* of the Royal Institution of London, constructed about the year 1801, on a plan suggested by Dr. Young and the Rev. W. Pearson, and described in the paper 'On Planetary Machines,' in the 'Edinburgh Encyclopædia,' by the latter gentleman.

The chief part of every orrery is the mechanism composing the planetarium, by means of which the paths of the planets about the sun and their relative periodic times are exhibited with more or less approach to truth: and this mechanism, with the method of computing it, being once understood, it will be easy to extend the same principles to the more complex cases in which the satellites revolve about their primaries at the same time that the latter rotate upon their axes and revolve about the sun, as well as to those in which the parallelism of the planets' axes and the changes in the positions of their orbits, &c. are sought to be represented. For this reason we shall confine ourselves to the method of computing the wheel-work, which will give the relative periods with any required degree of accuracy, and to the explanation of a very ingenious contrivance by means of which a true elliptic orbit may be produced. Before, however, proceeding to this, we would caution the purchasers of these expensive toys (those exhibited in the shops of mathematical instrument-makers vary in price from sixteen to forty guineas) against a defect which was at one time not uncommon and may still exist, and which, while it rendered them worse than useless, showed how little knowledge their contrivers could have possessed of the science they are intended to illustrate. We allude to the substitution of the synodic for the sidereal periods, whereby each planetary ball was made to revolve about the sun in the time which ought to have elapsed between two consecutive conjunctions of such planet with the earth.

To produce the revolution of the planetary balls about the sun, a system of vertical concentric tubes is usually employed, which are adjusted very near to each other, but yet so far removed as not to influence each other's motion. These tubes are of different lengths, the innermost being the longest, and to the superior extremity of each a radius vector is attached, and thereby made to revolve once during each revolution of the tube. The lower extremities of the tubes form the arbors or axes of as many toothed-wheels, which are either immediately driven by pinions adjusted to a vertical axle called the 'annual arbor,' or derive their motions indirectly from those pinions by means of an interposed train of wheels. The determination of the relative number of teeth which must be given to the wheels and pinions in order to produce any required motion may be thus explained.

A pinion generally means a wheel consisting of a less number of teeth than that which it drives, but in the present article this restriction is unnecessary. The teeth of a pinion are called *leaves*. The number of revolutions made by the wheel during one revolution of the pinion by which it is driven, is found by dividing the number of leaves in the pinion by the number of teeth in the wheel:—thus, if there be 35 leaves and 7 teeth, the wheel will make $\frac{35}{7}$ or 5 revolutions during one revolution of the pinion; but if there be 7 leaves and 35 teeth, the wheel will make $\frac{7}{35}$ or $\frac{1}{5}$ of a revolution during one entire revolution of the pinion. If to the axle of the wheel be adjusted a second pinion, which drives a second wheel, and if to the axle of this wheel a third pinion be adjusted which drives a third wheel, and so on, then the number of revolutions made by the last wheel during one revolution of the first pinion will be found by multiplying together the number of leaves in the several pinions, and dividing the result by the product of the number of teeth in the several wheels:—thus if there be four pinions, having 7, 8, 9, and 10 leaves respectively, and the same number of wheels, having 20, 21, 22, and 23 teeth respectively, the number of revolutions made by the last wheel during one revolution of the first pinion will be $\frac{7 \times 8 \times 9 \times 10}{20 \times 21 \times 22 \times 23} = \frac{6}{253}$, or, in other words, the last wheel will revolve six times during 253 revolutions of the first pinion. Conversely the ratio which the product of the number of leaves must bear to the product of the number of teeth, in order to produce any required relative motion between the first pinion and the last wheel, is found by dividing the number of revolutions made by the wheel by the number of revolutions to be made in the same time by the pinion. The actual number of teeth to be given to the wheels and pinions, as well as the number of wheels and pinions to be employed in any particular case, is matter of convenience, not of necessity: in every instance the employment of a single pinion and a single wheel is theoretically sufficient, but in practice it is generally desirable to avoid the use of wheels or pinions with a very large or very small number of teeth. In the planetarium of the Royal Institution the number of teeth is in no instance under 7, or above 137. In a more complete instrument, constructed by Dr. Pearson in 1813, the limits were 14 and 241. The same gentleman recommends about 10 teeth to the inch, which he considers "sufficiently strong, and not liable to unnecessary shake, when the teeth and spaces are made equal and at a proper depth for action." The lowest number employed by him was 7 to the inch, the highest 13.

Supposing we wish the radius which carries the ball representing the earth to revolve once during each revolution of the annual arbor, it is only necessary that the wheel which is adjusted to the lower extremity of the earth's tube should contain the same number of teeth as the pinion by which it is driven, and which is adjusted to the annual arbor. In this case each revolution of the annual arbor will be the measure of one solar year. If each revolution of the annual arbor be required to represent any assigned portion of a year, the necessary modification in the relative number of teeth in the earth's wheel and pinion will appear sufficiently obvious from what has preceded; but for the sake of simplicity, we shall assume that the earth's radius vector revolves exactly once during each revolution of the annual arbor, and upon this supposition we have now to fix the relative number of teeth which should be given to the wheels and pinions which regulate the motions of the other planetary balls. It generally happens that the number of revolutions which the radius vector of any one of the planetary balls is required to make during one revolution of the annual arbor is expressed in the form of a decimal. Suppose, for instance, that the relative motion required were that of the earth and Jupiter. Jupiter revolves in 4332·5848 mean solar days; the earth in 365·2564 mean solar days; the number of revolutions made by Jupiter during one revolution of the earth is therefore $\frac{365{\cdot}2564}{4332{\cdot}5848} = {\cdot}0843045$. If this decimal be converted into a continued fraction, the resulting series of fractions, which approximate more and more nearly to ·0843045, will be found to be $\frac{1}{11}$, $\frac{1}{12}$, $\frac{7}{83}$, $\frac{29}{344}$, $\frac{94}{1115}$, &c., any one of which, according to the degree of accuracy required, may be taken for the ratio which the number of leaves in the pinion must bear to the number of teeth in the wheel, if only a single wheel and pinion be employed, or the ratio which the product of the number of leaves must bear to the product of the number of teeth, if a train of wheels and pinions be employed. If the first of these fractions, or its equivalent, $\frac{7}{77}$, be taken, the wheel attached to Jupiter's tube should contain 77 teeth, and the pinion attached to the annual arbor by which it is driven should contain 7 leaves, and Jupiter's radius will then revolve once during 11 revolutions of the annual arbor, that is, in 365·2564 × 11 = 4017·8204 days, which is less than the true period by 314·7644 days. In the same manner may be found the time in which Jupiter's radius will revolve when any of the other fractions are taken, as under:—

$$\begin{array}{r} \text{days.} \\ 365{\cdot}2564 \times \end{array} \left\{ \begin{array}{lll} & \text{Period produced.} & \text{Error.} \\ & \quad\text{days.} & \text{days.} \\ \frac{11}{1} = & 4017{\cdot}8204 & 314{\cdot}7644\ - \\ \frac{12}{1} = & 4383{\cdot}0768 & 50{\cdot}4920\ + \\ \frac{83}{7} = & 4330{\cdot}897 & 1{\cdot}688\ - \\ \frac{344}{29} = & 4332{\cdot}699 & 0{\cdot}114\ + \\ \frac{1115}{94} = & 4332{\cdot}562 & 0{\cdot}025\ - \\ \text{\&c.} & \text{\&c.} & \text{\&c.} \end{array} \right.$$

The third of these fractions, or rather its equivalent, $\frac{166}{14}$, was the one employed by Dr. Pearson in the construction of his new planetarium; so that in that instrument the wheel attached to Jupiter's tube contains 166 teeth, and is driven by a pinion of 14 leaves attached to the annual arbor. In the planetarium of the Royal Institution, a train of wheels and pinions represented by the compound fraction $\frac{111}{22} \times \frac{94}{40}$ was employed, which therefore gives a period of

$$365{\cdot}2564 \times \frac{111}{22} \times \frac{94}{40} = 4330{\cdot}778 \text{ days.}$$

The contrivance by means of which a true elliptic orbit may be produced is extremely simple. For this purpose all that is necessary is that the radius vector which connects the planetary ball with the superior extremity of the tube should consist of two parts or arms, the lengths of which have a determinate ratio dependent solely upon the eccentricity of the orbit, and that while the larger arm revolves about the *centre* of the ellipse by means of the wheel-work already described, the smaller arm be made to revolve about the extremity of the larger with the same angular velocity but in the opposite direction. This may be effected in two ways. By means of a pulley *fixed* to the planetary tube and connected by an endless silken cord with another pulley free to revolve about a vertical axle situated at the extremity of the larger arm. The effect of this connection will be that the latter pulley will revolve once during each revolution of the larger arm but in the opposite direction. If, therefore, the smaller arm be attached to this pulley it will revolve in the manner required. The same motion may be produced by employing a double pinion extending the entire length of the larger arm and communicating the rotatory motion given to it at one extremity, to the axle of the smaller arm situated at the other.

ORSELLIC ACID. [LICHENS, *Colouring matters of.*]

ORTHOGONAL, ORTHOGRAPHIC. The first of these terms, when not used in the same sense as the second, means simply perpendicular. Thus a curve cuts a set of curves orthogonally when it cuts them all at right angles.

Orthogonal or orthographic projection is that which is made by drawing lines from every point to be projected, perpendicular to a plane of projection. Thus if a plane were horizontal, and a point were to drop from a given position upon the plane, its last position would be the orthogonal or orthographic projection of its first.

ORTHOGRAPHY. When this word is looked at in its elements (two Greek words denoting *the art of writing* and *correctness*), it would seem that there ought to be included under it whatever belongs to the art of writing a language correctly, including both what is called etymology and syntax. But the grammarians have given it a restricted sense, and it is used to denote not the writing correctly in the general, but the proper selection of literal elements of each word that is used, and the proper division of each word when one part of it is at the end of one line and another at the beginning of the line which succeeds. In the ancient Hebrew manuscripts we may observe that this division of words never occurs, the scribes resorting to the expedient of widening certain of the letters, if in the ordinary form the words would not fill up the line. The law-stationers, in their copies of legal documents, fill up a line with a waved and unmeaning stroke, when the word which follows cannot conveniently be written in it at length.

We perceive by certain grammars and dictionaries published by practical men, both at home and still more in the United States of North America, that the writers appear to suppose that their works will be resorted to even by persons of cultivation as authorities or guides to orthography. But we believe it to be the case that the number is very few of persons who actually use dictionaries for this purpose. We mean, of course, not mere children or persons of very imperfect education; but even of those there are very few persons who read much and write occasionally, who ever think of resorting to books of the kind we are speaking of; while persons of a better education trust entirely to memory, and should a doubt arise, the reference would be made to some eminent author, and not to the guides of which we speak. In fact, the art is acquired almost without teaching, and is maintained in vigour through a whole life by the constant practice of writing and reading. At all events, there is no book, grammar, guide, or dictionary, which a scholar in England regards as in this point a book of authority.

Whether it would be expedient to raise some one work into an authority in such a point as this, is, in fact, a question—one of the greatest in philology that can be proposed—whether there shall be an invariable standard established to which a living language shall for ever conform. We doubt not only the possibility but the expediency of this; and in respect of orthography, we are quite sure that no such standard can be raised, because it would be quite impracticable to bring all persons who have a right to a voice in such a matter to an agreement in any one system involving the admission of certain fixed principles. The contemporary usage of persons of cultivation, meaning of a great preponderating majority, which will always exist, is, we apprehend, the authority to which each person who aspires to write correctly must continue to defer.

This has been the standard to which reference has always hitherto been made. Open any book printed in the reign of Queen Anne, and many words will present themselves in an orthography very different from that in which they would now be found. But we must not say that the persons who wrote them wrote incorrectly, if they wrote according to the practice of the cultivated persons of their time. If we ascend still higher, and go to the reign of Elizabeth, we find the orthography still more diverse from our own; and when we reach the time of Caxton, and still more when we go back to the days of Chaucer and Wycliffe, we find many words which, though they are actually words now in use, are so disguised in form that we can scarcely recognise them. We seem to have got among a people who spoke a different language, though they were our own forefathers, not more than some fourteen generations removed.

This has arisen from the want of a standard—something fixed, not varying like usage. There is an inconvenience in it as respects the writers before the time of Caxton and the invention of printing, and we may reasonably wish that, with reference to them, there had been some less varying standard and a continuous uniformity; but when we look in the writings of the men of the Elizabethan period, we find that, though now two centuries and a half have passed, there is no more difficulty in perusing them than there is in perusing the writings of our own day; and that the same will be the case in respect of the writings of the present day in the hands of Englishmen four or five centuries hence, may be safely foretold. So that there is no real prejudice arising from the unphilosophical and dangerous course of leaving this point to be regulated by anything so uncertain as contemporary usage.

At present the number of words of which the orthography is not uniform in all writings which aspire at once to be correct and devoid of affectation, is exceedingly small. Take this sentence, and the whole of the paragraph which precedes it; is there any word, except this word *precede*, in which any variety will be found in the ordinary current writings of the day? Or if we found a variety, should we not say that the deviation from the usual practice was a casual mistake, a slip of the press, an affectation, or that it was the result of some peculiar principle which some peculiar person had adopted? And even this word *precede*, though it belongs to a class in which orthography is not uniform, we should probably very rarely find written in any other way, for few persons would prefer the form *preceed*, if indeed such a form is ever used. So that practically a great and perhaps quite sufficient degree of uniformity and stability may be said to be secured under the regulating power which now exists.

Dictionaries and vocabularies, as affording an easy guide to the knowledge of what is the usage, may have their use in this respect to a few persons who write occasionally only; but as authorities, we repeat, they are of no avail.

It has been matter of complaint that the orthography of the English language is not more uniform; that is, that words which are composed in whole or in part of the same elements are not uniform in the manner in which those elements are exhibited. Thus all words derived of the Latin *cedo* with prepositions prefixed, it may be said, should be in one form; and it is a variety in defence of which nothing can well be pleaded that we should write *proceed* and yet write also *concede*. So with respect to such words as *honour*, *favour*, *odour*, *labour*, it may be said that there should be uniformity with other words like them, in which the *u* is not found; and further, that we should keep to the orthography of the Latin words of which they are forms equally in meaning and orthography. This appears plausible, but when it is considered that these words do not come to us *immediately* from the Latin, but have passed to us through the French, we recognise in the unnecessary letter *u* a part of the history of the word, which a person of true taste would scarcely be willing to relinquish for an advantage so trivial. Or take the rough word *through*: some may think that the three last letters may well be dispensed with, but they remain a pleasing evidence of the origin of the word in the rough and strong speech of our Saxon ancestors.

These little irregularities in orthography, like irregularities in other parts of grammar, are not to be regarded as evils. Such irregularities give birth to what are called *idioms*, in which no small part of the beauty of a language lies.

Attempts have, however, been made by ingenious men to introduce a greater degree of uniformity into our orthography. There is a treatise on the management of bees, printed about two centuries ago, in which we have a peculiar orthography on a system of the author's own. Ritson, in the last century, in some of his works adopted an orthography of his own. Professed writers on grammar have done the same; some of them to such an extent that the language, as written by them, can scarcely be known to be English. A more moderate reform is attempted by an American writer, Dr. Noah Webster, the author of the English Dictionary, which has been reprinted in this country; and Mr. Bromby of Hull, a learned and ingenious clergyman, has printed for private circulation a translation of the treatise of Plutarch concerning music, in which the orthography is regulated by certain principles which he lays down in the preface. Again, some gentlemen, distinguished alike by intelligence and philanthropy, a few years ago brought forward a well-considered form of alphabet, and gave to the world an example of it in the periodical called the 'Fonetik Nuz.' It would be well, perhaps, if philological inquirers and missionaries availed themselves of this notation, when dealing with unwritten languages, or with those whose alphabets differ wholly or widely from all that is familiar to Europeans. Further, it may be conceded that the acquisition of the English language itself by young children would be greatly facilitated by the use of school-books on the "Fonetik" system as stepping-stones to our ordinary form of printing. No doubt it is some slight evil that the strict reduction of our written signs to harmony with spoken language would involve a sacrifice of much that is valuable for etymological guidance. But any loss on this side would be more than compensated by the increased facilities for attaining the language. The valid objection to the proposal is, the utter impossibility of effecting so extensive a revolution. It is most true, and it is also a serious evil, that our mode of spelling is so anomalous and inconsistent; yet the words are in reality very few of which the orthography may not be said to be now *established* by the great *Jus et Norma Loquendi*—custom. We take the following from a modern grammar, as being those which, in the opinion of the writer, are most frequently found with orthographical varieties:—

honour	honor
inquirer	enquirer
negotiate	negociate
control	controul
expense	expence
allege	alledge
complete	compleat
connexion	connection
abridgment	abridgement
surprise	surprize

Of course some of these represent classes. But what are these to the great body of such a language as ours? And with respect to the first and to the last, each of which represents a large family of words, we would submit that very few persons indeed who were entitled to a voice in a question of this kind would be found writing *honor;* and that there is a general rule respecting words in *ise* or *ize*. The rule is this: when the word is a derivative of the French *prendre*, as is the case with *surprise*, *enterprise*, and one or two others, to write it with the *ise;* but when it comes to us from the Greek, as in *agonise*, and other words, to keep the Greek termination *ιζω*—*Anglicé*, *ize*.

ORUS, or **HORUS**, an Egyptian deity, the son of Isis and Osiris, corresponds, according to Herodotus, to the Apollo of the Greeks, and was the last of the gods who reigned in Egypt. (Herod., ii. 144; Diod., i. 44.) Typhon, after the murder of his brother Osiris, sought to kill Orus; but his mother Isis, according to Herodotus (ii. 156), committed him to the care of Leto, who brought him up in the moving island of Chemmis, which was in the lake Buto. The Egyptian priests, however, in this instance, as well as in many others, appear to have been anxious to assimilate the history of their deities as much as possible to that of the Greeks. Orus, from the death of Osiris stood forth as the avenger of his father; and when he had grown up, he made war upon Typhon, whom he defeated in several battles, deprived of the kingdom of Egypt, and, according to some accounts, put to death. (Diod., i. 25; Herod., ii. 144; Plutarch, 'De Is. et Osir.,' p. 358, Francfort, 1620.)

According to Diodorus (i. 25), Orus was killed by the Titans, and restored to life by his mother Isis, who conferred upon him immortality, and taught him divination and the healing art; a fable which Wilkinson thinks "explained by the historical fact of the priesthood of different gods having ruled Egypt before the monarchical form of government was established in the person of Menes and his successors." (Wilkinson, 'Ancient Egyptians,' iv. 397.) Little reliance, however, as he adds, is to be placed on what the Greeks relate of the deities of Egypt.

Orus is frequently represented as sitting in the lap of Isis, but more commonly standing in a boat along with other deities, and piercing the evil being, Typhon, who is in the water, either in the form of a man, or of a long serpent. Orus appears also to be represented in some bronzes in the British Museum, which depict a man trampling on the crocodile, since we know that the crocodile was one of the symbols of Typhon. The symbol of Orus is a hawk, who, sometimes in later works, is figured perched on an oryx: and the god himself is represented with the head of a hawk crowned with the pshent, or double crown of Upper and Lower Egypt. (Wilkinson, iv. c. 13; 'Egyptian Antiquities,' vol. ii. p. 306.)

ORYZA, the name by which rice was known to the Greeks and Romans, and which has been adopted by botanists as the generic name of the plant yielding that valuable grain. [ORYZA, in NAT. HIST. DIV.]

The rice plant is undoubtedly a native of India, from which country it has spread over a great part of the world, especially in Asia, where it forms the principal portion of the food of the inhabitants, but it has also from very early times been introduced into the southern parts of Europe. Theophrastus describes it in book iv. c. 5, with other Indian plants, and mentions it as growing in water, and that its inflorescence is like that of milium or panicum, and not in form of a spike. Rice is now extensively cultivated in North and South Carolina, and in Georgia; also in Italy and the south of Spain, and likewise a little in Germany. The perfect system of irrigation and tillage which was introduced into Italy at so early a period no doubt rendered the cultivation easy, as the climate is also sufficiently hot and regular.

As the summer temperature of many countries is high, it is easy to cultivate an annual like rice where water is abundant and irrigation easy; but as the summer temperature of most European countries is too low, and not long enough continued, and far from regular, it is hopeless to attempt the culture of a grain which requires so much heat, and which has the disadvantage, from the moisture arising from irrigation, of making a country unhealthy; but this is not the case in the rainy season of tropical countries, where the rice-field is not much more moist than the rest of the country. Its culture has been attempted in England, and a small crop was raised near Windsor, on the banks of the Thames. It has been hoped that the mountain rice, which is known to grow at considerable elevations in the Himalayan Mountains, might be suited to an English climate. This variety certainly requires a less degree of heat, but it seems to be forgotten that temperature is only one of the elements of climate, and that moisture may be supplied to a plant either by the soil or the atmosphere, and the latter may be moist when the former is comparatively dry. Rice is sown in the Himalayas only in places within the influence of the periodical rains, that is, from about the middle of June to the end of September. In some places it is irrigated, and in others it is not, but rain falls very frequently, and the air is almost always in a moist state, from being charged with moisture from the heated valleys, which is deposited on the mountains, when it reaches an elevation where it becomes cooled beyond the point of saturation. The temperature also is so uniform as not to vary 10° of Fahr. from 70° for three months. So in the Isle of France the mountain rice is cultivated only in the rainy season.

The rice so extensively cultivated throughout India (and the cultivation in China, as described by Sir G. Staunton, is very similar) depends upon rain or irrigation either from rivers or tanks. These Captain B. Hall ('Frag. of Voyages,' vol. iii. p. 88) describes in one situation, near Nundydroog, as spread over a valley, which was from six to eight miles across, and that they were used for irrigating myriads of rice-fields. The embankments are sometimes miles in length, and then of a waving snake-like shape. One valley was pointed out to Captain Hall, about a mile broad and forty miles long from end to end, which included between thirty and forty tanks, every intermediate square yard of the intermediate spaces being richly cultivated, while the surrounding country appeared to be condemned to perennial sterility.

Dr. Roxburgh states that he never saw or heard of an Indian farmer manuring in the smallest degree a rice-field; yet these fields have probably for thousands of years continued to yield annually a large crop of rice, on an average from thirty to sixty fold; even eighty or a hundred has been known. The best rice-fields are extensive open plains through which large rivers pass. The soil is generally of good depth; the best are those annually overflowed by the inundations, from which they necessarily receive some fertilising matter; but the greatest part of the rice lands depend on the rains only, and receive no help except from it and the air. The varieties of rice are innumerable; forty or fifty at least are described. They are divided by Dr. Roxburgh into two kinds: one, called in Telinga, *Poonas*, Sans., *Asoo*, is sown thick in June or July, and transplanted in about forty days, when the plants are about nine to eighteen inches high; the fields are then kept constantly wet; more or less flooded, as some sorts require very little water, while others require a great deal. When the grain is ripe, the water is drained off, and the crop cut down with the sickle; it is either stacked or trod out by cattle. The grain is preserved in pits dug in high ground and lined with the rice straw. The straw is stacked by the careful farmer for feeding his cattle during the hot weather.

The second division of cultivated rice is called *Pedder Worloo* by the Telingas. The grains are awnless, and both the unhusked and husked rice, in most varieties, is white and of excellent quality, though some require much water. In other parts of the country rice is divided, according to the seasons in which it is reaped, into that which ripens in the hot weather of spring, in the summer, or in the winter.

Buchanan states that two crops in the year from the same land do not yield much more than a single good crop would. But the seasons are so uncertain, and the latter crop so liable to fail, that they cultivate as much as possible for the first crop. This is reaped in the rainy season, when the straw cannot be preserved, and as rice-straw is almost the only food which the cattle have in many districts, there is an absolute necessity for sowing the second crop for fodder.

Rice is no doubt the grain which yields food for the largest portion of the human race, but even in India great numbers do not eat rice; in fact, in all the north-western provinces wheat is the principal crop, and the natives eat wheaten cakes, and have rather a contempt for rice-eating districts. It abounds, however, in nourishment, being composed almost entirely of fecula, that is, 96 per cent., and therefore cannot be baked into bread; but it is more easily cooked. It is light and wholesome, and easily digested, and might form a much larger portion of the diet in Europe than it does. Europeans in India eat it at breakfast as well as at other meals, and with fish as frequently as with their curries.

Of the kinds imported into England, the Carolina is the best, and is grown in the marshy grounds of North and South Carolina. The grains are shorter, broader, and boil softer than the Patna rice, which is the best Indian kind known in this country, though in India there are several superior varieties, as for instance the Rilibeet, which are much more esteemed there. In the year 1859, 3,692,023 cwts. were imported into England. The quantity retained for consumption in the United Kingdom was 1,761,865 cwts.; of the estimated value of 1,652,505*l*. The relative values may be judged of by the price of the Carolina rice being 20*s*. when the Patna was 17*s*.; Bengal white, 12*s*.; and the Cargo only 9*s*. 6*d*. The Cargo is a reddish-coloured, coarse, but sweetish grain, which is liked by the lower caste of natives of India.

OSCI, or OPICI, a people of ancient Italy, who seem to have been identical with the Ausonians, or Aurunci, and who inhabited the central part of the peninsula—from Campania and the borders of Latium to the Adriatic. Some ancient writers consider the Ausonians to be a branch of the Osci; others, as Polybius, have spoken of them as distinct tribes, but this appears to be an error. The names Opicus and Oscus are undoubtedly the same. Aristotle ('Polit.,' vii. 10) calls the country from the Tiber to the Silarus, Ausonia and Opicia; and other ancient writers extended the name much farther, to the Straits of Sicily, but the southern extremity of the peninsula appears to have been occupied by the Œnotrians, a Pelasgic people, who were conquered by the Lucanians and Bruttii. Cumæ, one of the earliest Greek colonies on the coast of Italy, was in the country of the Opici. There was an ancient tradition in Italy in the time of the historian Dionysius, of a sudden irruption of strangers from the opposite coast of the Adriatic, which caused a general commotion and dispersion among the aboriginal tribes. Afterwards came the Hellenic colonies, which occupied the whole sea-coast from Mount Garganus to the extremity of the peninsula, in the first and second centuries of Rome, in consequence of which the population of the southern part of the Italian peninsula became divided into two races, the tribes of aboriginal or Oscan descent, such as the Sabini, Samnites, Lucanians and Bruttii, who remained in possession of the highlands, and the Greek colonists and their descendants, who occupied the maritime districts, but never gained possession of the upper or Apennine regions. Such is the view taken by Micali and other Italian writers; but Niebuhr ('History of Rome,' vol. i.) describes the Sabini, and their colonies the Samnites, Lucanians, and other tribes which the Roman writers called by the general name of Sabellians, as a people distinct from the Osci or Opici. He says, after Cato and other ancient historians, that the Sabini issued out of the highlands of the central Apennines near Amiternum, long before the epoch of the Trojan war, and driving before them the Cascans or Prisci Latini, who were an Oscan tribe, settled themselves in the country which has to this day retained the name of Sabina. From thence they sent out numerous colonies, one of which penetrated into the land of the Opicans, and became the Samnite people; and afterwards the Samnites occupied Campania, and, mixing themselves with the earlier Oscan population, settled there, and adopted their language. But further on, speaking of the Sabini and Sabellians, Niebuhr admits the probability of their being originally a branch of the same stock as the Opici or Osci. Micali considers the Sabini, Apulians, Messapians, Campanians, Aurunci, and Volsci, as all branches of the great Oscan family.

The Greeks, being superior to the native tribes in refinement and mental cultivation, affected to despise them, and they applied to the native Italian tribes, including the Romans, the adjunct Opican, as a word of contumely to denote barbarism both in language and manners (Cato apud Pliny, xxix. 1); and the later Roman writers themselves adopted the expression in the same sense: "Osco loqui" was tantamount to a barbarous mode of speaking. Juvenal (iii. 207) says:

"Et divina Opici rodebant carmina mures;"

and Ausonius uses "Opicas chartas" to mean rude unpolished compositions. The Oscan language was the parent of the dialects of the native tribes from the Tiber to the extremity of the peninsula, Sabini, Hernici, Marci, Samnites, Sidicini, Lucanians, and Bruttii, and it was evidently a cognate dialect with the Latin; whilst in the regions north of the Tiber the Etruscan predominated. Livy (x. 20) mentions the Oscan as being the language of the Samnites The older Latin writers, and especially Ennius, have many Oscan words and Oscan terminations. The Oscan language continued to be understood in many parts of Italy down to a late period under the empire. The ATELLANÆ FABULÆ doubtless originated with them, though probably Strabo is mistaken in asserting that they were performed at Rome in his day in the Oscan language. In the Social War, the Confederates, who were chiefly people of Oscan descent, stamped Oscan legends on their coins. In Campania and Samnium the Oscan continued to be the vulgar tongue long after the Roman conquest, as appears from several monuments, and especially from the Oscan inscriptions found at Pompeii, and the bronze tablet found at Agnone in northern Samnium, which gives a list of offerings at a dedication. (Micali, 'Storia degli Antichi Popoli Italiani,' ch. xxix., and 'Atlas,' pl. 120.

The Oscan race, like the Etruscan, appears to have been from the remotest times strongly under the influence of religious rites and laws (Festus, under the head 'Oscum'), and the primitive manners and simple morals of the Oscan and Sabine tribes, as well as their bravery in arms, have been extolled by the Roman writers, among others, by Virgil ('Æneid,' vii. 728–730), and Silius Italicus (viii. 526–529).

Concerning the scanty remains of the Oscan language which have come down to us, see 'Linguæ Oscæ Specimen singulare quod superest Nolæ in marmore Musæi Semiuarii,' which is given by Passeri, in his 'Picturæ Etruscorum in Vasculis,' &c., Rome, 3 vols. fol., 1767–75; also Guarini, 'In Osca Epigrammata nonnulla Commentarium,' Naples, 8vo, 1830, where several Oscan inscriptions are found collected. Klenze, 'Philologische Abhandlungen,' 1839; and Mommsen, 'Unter-Italieni sche Dialekte,' 1850. For Niebuhr's views on the Opici or Osci, see his 'Roman History,' vol. i.

OSCILLATION and CENTRE OF OSCILLATION. When any system is slightly disturbed from its position of equilibrium, it either falls altogether or endeavours to recover the position which it lost. In the latter case the equilibrium is said to be stable, and in the former unstable. A pendulum hanging downwards is an instance of the stable kind, and the same pendulum, if it could be so nicely adjusted as to rest immediately over the pivot, would be of the unstable kind. [STABLE AND UNSTABLE.]

When a system endeavours to recover its position, it acquires some velocity in the process; so that, though it would rest at the position of equilibrium if that velocity were then destroyed, it is really urged through the position by the velocity acquired, and continues to depart from it on the other side until, by the forces which act to restore it to the position, all the velocity acquired has been destroyed. Repetitions of the same phenomenon then take place in succession, the body never remaining still when it has attained the position of equilibrium, since it never is in that position except when moving with the velocity acquired in its descent to that position. If then there were neither friction nor resistance of the air to help in destroying this velocity, it would be a universal law of mechanics that a system disturbed from its position of equilibrium would never recover it, but would make perpetual oscillations about it.

In the widest sense, the problem of oscillations includes most of those which occur in astronomy, optics, &c. The moon and planets add to their average motions small oscillations about their mean places: the tides consist of oscillations of the ocean about the uniform spheroid, which, but for the action of the heavenly bodies, would be carried round in the diurnal rotation of the earth; the phenomena of light are produced by the oscillations which take place in an elastic æther; those of sound by the oscillations of the air; and so on. Usually, however, the problem of oscillation refers to nothing more than the oscillations of a solid system, acted on by gravity, about a horizontal axis, the original departure from the position of equilibrium being but small; in fact, to the purely theoretical part of the problem of the PENDULUM, to which we shall here confine ourselves, giving the investigations in a brief form, since it is impossible, within our limits, to explain the numerous points alluded to with sufficient illustration for a learner.

Let a material point, a very small body, be attached by a string or rod without weight to an immovable pivot. In the position of rest the string hangs vertically: let us now suppose it removed out of the vertical position, and let go when it makes an angle α with the vertical. When t seconds have elapsed, let it make an angle θ with the vertical. The material point is acted on by gravity with a force which would produce an acceleration g (or 32·1908) feet nearly, in one second: if then l be the length of the string, $l\theta$ is the arc, through which the point must move before it arrives at the lowest point of its course, and we have by the well-known equations of motion,

$$\frac{d^2 . l\theta}{d t^2} = - g \sin\theta, \text{ or } l\frac{d^2\theta}{dt^2} + g\sin\theta = 0.$$

The first integration of this gives

$$l\left(\frac{d\theta}{dt}\right)^2 = 2g\,(\cos\theta - \cos\alpha),$$

since it is a condition that the motion began when θ was $= \alpha$. This gives

$$dt = -\sqrt{\frac{l}{g}}\;\frac{d\theta'}{\sqrt{(\sin^2\alpha' - \sin^2\theta')}}$$

α' and θ' being the halves of α and θ, and the negative sign being taken because θ' diminishes as t increases. The integration of this is facilitated by assuming $\sin\theta' = \sin\alpha' . \sin\phi$, which gives

$$\sqrt{(\sin^2\alpha' - \sin^2\theta')} = \sin\alpha'\cos\phi,$$

$$d\theta' = \frac{\sin\alpha'\cos\phi\,.\,d\phi}{\sqrt{(1 - \sin^2\alpha' . \sin^2\phi.)}}$$

$$dt = -\sqrt{\frac{l}{g}}\,.\,\frac{d\phi}{\sqrt{(1 - \sin^2\alpha' . \sin^2\phi)}}$$

$$= -\sqrt{y}\,.\left\{1 + \frac{1}{2}\,\mathrm{P}^2 + \frac{1\,.\,3}{2\,.\,4}\,\mathrm{P}^4 + \frac{1\,.\,3\,.\,5}{2\,.\,4\,.\,6}\,\mathrm{P}^6 + \,.\,.\right\}d\phi$$

where r stands for $\sin\alpha' \,.\, \sin\phi$. To find the time of a semi-vibration, this must be integrated from $\theta' = \alpha'$ to $\theta' = 0$, or from $\phi = \frac{1}{2}\pi$ to $\phi = 0$, that is, after change of sign, from $\phi = 0$ to $\phi = \frac{1}{2}\pi$. Now between these limits

$$\int \sin^{2n}\phi \,.\, d\phi = \frac{1\,.\,3\,.\,5\,\ldots\ldots\,\overline{2n-1}}{2\,.\,4\,.\,6\,\ldots\ldots\,2n} \cdot \frac{\pi}{2}$$

whence, changing the sign of the preceding and integrating each term by this formula, we find the time of a semi-vibration. Double this, to find the time of a vibration, which call T, and we have

$$T = \pi\sqrt{\frac{l}{g}} \cdot \left\{1 + \frac{1}{4}\sin^2\alpha' + \frac{1\,.\,9}{4\,.\,16}\,\underline{\sin^4\alpha'} + \frac{1\,.\,9\,.\,25}{4\,.\,16\,.\,36} \cdot \underline{\sin^6}\,\alpha' + \ldots\ldots \right\}$$

a very convergent series. If α' be small, we have, with an error of the second order only,

$$T = \pi\sqrt{\frac{l}{g}};$$

or the time of vibration of the same pendulum in different small arcs is very nearly independent of the lengths of the arcs; a result which might be obtained from the considerations given in the article Isochronism. To take in two terms of the series is very nearly equivalent to multiplying the preceding value of T by $1 + \frac{1}{16}\alpha^2$.

The number of vibrations in a mean solar day of the pendulum whose length is l, placed in a vacuum, is

$$\frac{86400\sqrt{g}}{\pi\sqrt{l}}\left\{1 - \frac{1}{16}\,\alpha^2\right\} \text{ very nearly.}$$

Oscillation, centre of.—Let a number of material points invariably connected together vibrate about a horizontal axis. It is required to find at what distance a single material point must be hung that it may vibrate in the same manner.

Let there be a number of material points, or infinitely small bodies, having the masses m, m', m'', &c., invariably connected with each other, and with an horizontal axis of rotation, their perpendicular distances from the axis being l, l', l'', &c. Let $M = m + m' +$, &c., be the sum of all the masses, and let k be the perpendicular distance of the centre of gravity of the whole from the axis. When the last-mentioned perpendicular distance makes an angle θ with the vertical, the moving force is Mg acting in the direction of gravity at the distance $k\sin\theta$, and acting with a moment of rotation $Mgk\sin\theta$. Let ϕ be the angular velocity at the time in question, which becomes $\phi + d\phi$ at the end of a new interval dt; then taking the mass m into consideration, we have $l\phi$ for its actual velocity, and $l\,d\phi$ for the increment in the time dt, whence $m\,l\,d\phi$ is the actual momentum gained, $m\,l\frac{d\phi}{dt}$ the moving force which would produce that momentum. This force acting at the distance l, and perpendicularly to that distance, would exert a moment of rotation $m\,l^2\frac{d\phi}{dt}$. Ascertain in the same way the moments of rotation of the other masses; then by the equivalence of the impressed and effective forces [Virtual Velocities] we must have—

$$m\,l^2\frac{d\phi}{dt} + m'l'^2\frac{d\phi}{dt} + \ldots \quad = Mgk\sin\theta.$$

But ϕ is $-\frac{d\theta}{dt}$, thus written since $\frac{d\theta}{dt}$ is negative; if then we denote $ml^2 + m'l'^2 + \ldots$ (which is the Moment of Inertia) by $\Sigma m l^2$, we readily deduce from the preceding

$$\frac{d^2\theta}{dt^2} + \frac{Mk}{\Sigma ml^2} \cdot g\sin\theta = 0.$$

The question of the motion of this system is now completely reduced to that of a simple pendulum; for if we compare the preceding equation with that of the motion of a simple pendulum, we find that the two would agree if the length (there called l) of the simple pendulum were $\frac{\Sigma ml^2}{Mk}$ or:—any rigid system which makes oscillations about an horizontal axis, oscillates in the same manner as a simple pendulum, the length of which is the moment of inertia of the system with respect to its axis divided by the product of the whole mass and the distance of the centre of gravity from the axis. If in the line k or its continuation, a distance equal to $\frac{\Sigma ml^2}{Mk}$ be set off from the axis, the moving extremity is called the centre of oscillation, as being that point in which the whole mass might be collected without any alteration of the law of oscillation.

Let G be the moment of inertia when the axis passes through the centre of gravity and is parallel to the given axis; then [Moment of Inertia] $\Sigma m l^2 = G + Mk^2$, whence the distance of the centre of oscillation from the axis is $\frac{G + Mk^2}{Mk}$, or $\frac{G}{Mk} + k$. Hence the centre of oscillation is always farther from the axis than the centre of gravity by $\frac{G}{Mk}$. Let this be called h: we have then

$$hk = \frac{G}{M}.$$

Now G and M are independent of the position of the axis, G depending only on the masses and manner in which the masses are distributed about the centre of gravity, and M on the amount of the masses. If then a new axis of suspension were taken, distant by h from the centre of gravity on the other side, that is, if a new axis of suspension were taken passing through the first centre of oscillation, and if h' were the distance of the new centre of oscillation from the centre of gravity, we should have

$$h'h = \frac{G}{M}, \text{ but } hk = \frac{G}{M}, \text{ whence } h' = k:$$

that is, the old axis of suspension contains the new centre of oscillation, if the new axis of suspension contains the old centre of oscillation. This is generally expressed thus: the centres of suspension and oscillation are convertible. When the body is a continuous mass, the preceding investigations apply, but the integral calculus must be employed to determine G.

OSCULATION, a term used instead of contact by foreign writers. [Contact; Tangent.]

OSCULUM PACIS. [Pax.]

OSI'RIS, one of the principal Egyptian deities, was the brother of Isis and the father of Orus [Isis; Orus], and is said by many writers to have been the first king of Egypt. His history is given in the first book of Diodorus, and in the treatise of Plutarch, 'On Isis and Osiris;' but it is probable that the genuine Egyptian traditions respecting this deity had been considerably corrupted at the time of these writers. According to their accounts however, Osiris was the first who reclaimed the Egyptians from a state of barbarism, and taught them agriculture and the various arts and sciences. After he had introduced civilisation among his own subjects, he resolved to visit the other nations of the world, and confer on them the same blessing. He accordingly committed the administration of his kingdom to Isis, and gave her Hermes to assist her in council and Hercules to command her troops. Having collected a large army himself, he visited in succession Ethiopia, Arabia, and India, and thence marched through central Asia into Europe, instructing the nations in agriculture and the arts and sciences. He left his son Macedon in Thrace and Macedonia, and committed the cultivation of the land of Attica to Triptolemus. After visiting all parts of the inhabited world, he returned to Egypt, where he was murdered soon after his arrival by his brother Typhon, who cut up his body into twenty-six parts, and divided it among the conspirators who assisted him in the murder of his brother. These parts were afterwards, with one exception, discovered by Isis, who enclosed each of them in a statue of wax, made to resemble Osiris, and distributed them through different parts of Egypt. This myth appears to allude to the fact mentioned by Herodotus, that Osiris was the origin of the mummy form. After leaving this world Typhon, or the evil principle, was overcome by his influence. For the various explanations of the myth of Osiris, see Wilkinson, 'Ancient Egyptians,' iv. 333, &c.

Both ancient and modern writers have differed considerably respecting the peculiar attributes and powers of this deity. He appears to have been the representative of the supreme beneficence. The worship of Osiris consequently was universal in Egypt—though, says Herodotus, it was not customary for all the Egyptians to worship the same god, every one paid adoration to Osiris and Isis. Wilkinson says that Osiris differed from most of the other Egyptian deities, inasmuch as they were regarded as human beings who were deified after death, whereas Osiris was a manifestation of deity in a human form; and this was "the profound secret revealed only to some of those who were initiated into the highest order of the mysteries." ('Ancient Egyptians,' iv. 317.) Many of the ancients believed that he represented the sun or the Nile; while his discovery of the vine and his expedition to India led others to identify him with Dionysus. (Herod., ii. 144.) Herodotus informs us (ii. 48) that the festival of Osiris was celebrated in almost the same manner as that of Dionysus. It appears however not improbable that the worship of Osiris was introduced into Egypt, in common with the arts and sciences, from the Ethiopian Meroe. We learn from Herodotus (ii. 29) that Zeus (Ammon) and Dionysus (Osiris) were the national deities of Meroe; and we are told by Diodorus (iii. 3) that Osiris led a colony from Ethiopia into Egypt.

Osiris was venerated under the form of the sacred bulls Apis and Mnevis (Diod. i. 21); and as it is usual in the Egyptian symbolical language to represent their deities with human forms and with the heads of the animals which were their representatives, we find statues of Osiris represented with the head or the horns of a bull, accompanied with the name Apis-Osiris (Wilkinson, iv. 347).

Osiris, in common with Isis, presided over the world below; his principal office as an Egyptian deity, was to judge the dead, and he is commonly represented on rolls of papyrus as sitting in judgment on departed spirits. His usual attributes are the high cap, the flail or whip, and the crosier; and he is clothed in white. Sometimes he is figured with a hawk's head. He is also frequently represented with an artificial beard. His titles are very numerous: Wilkinson notices some of the principal (iv. 320). By the Greeks he was identified with Dionysus. But Diodorus says that some have supposed him to be Pluto, Pan, and even Zeus. The mysteries of Osiris, with which were conjoined those of Isis, were practised with great secrecy and solemnity. It was from them that the Eleusinian mysteries were derived. (Diodorus, i. 29; Herodotus, ii.) The chief seats of his worship were Philæ and Abydos; at the former of which the great mysteries were celebrated.

OSMANOSMIC ACID. [Osmium.]

OSMIC ACID. [Osmium.]

OSMIUM (Os). From *οσμη, odour*, in allusion to the smell of osmic acid. This metal was discovered by Mr. Smithson Tennant in the year 1803, in the grains of native platinum [Platinum], along with another metal [Iridium]. This compound, called *osmide of iridium*, occurs in flat grains and hexagonal crystals. The primary form is a rhomboid. Cleavage, perpendicular to the axis. Hardness 4·5 to 5·1, exceeding that of native platinum. Colour iron-gray and pale steel-gray. Lustre metallic. Opaque. Specific gravity 19·5. Insoluble even in aqua regia; becomes black when fused with nitre, and when heated in a tube exhales a peculiar odour.

Berzelius analysed three varieties of osmide of iridium, from Siberia, with the annexed results.

Osmium	80	74·9	49·34
Iridium	20	25·1	46·77
Rhodium	..	..	3·15
Iron	..	..	0·74
Palladium	..	..	trace.
	100	100·0	100·00

The preparation and properties of osmium have lately been studied by MM. Deville and Debray. These chemists have obtained it in the pulverulent, crystallised, and compact forms, by the following processes. Osmide of iridium powdered, if necessary, by roasting with zinc, is mixed with five and a half times its weight of binoxide of barium and heated in a well covered crucible to the temperature of melting silver, for two hours. The resulting black mass is then broken up, distilled in a retort with eight parts of hydrochloric acid and one of nitric acid, the well cooled distillate redistilled, and the vapours condensed in dilute ammonia. The osmiate of ammonia solution thus formed is then saturated with sulphuretted hydrogen and boiled, and the sulphide of osmium reduced by heating for four or five hours, in a carbon crucible, to the temperature of melted nickel or melted rhodium.

Osmium thus obtained is *pulverulent*, but exhibits the metallic lustre with considerable brilliancy; has a blue colour brighter than that of zinc; a specific gravity of 21·3 or 21·4, and, at a temperature higher than that of melted zinc, is combustible. Heated to bright redness, with eight times its weight of tin, in a carbon crucible, and the melted mass allowed to cool slowly, it separates out in a *crystalline* form, and is isolated on dissolving out the tin with hydrochloric acid. Heated by the oxyhydrogen blowpipe, in a furnace made of lime, it does not fuse, but aggregates into a more or less compact mass, and at the heat of melted iridium is slowly dissipated in vapour.

Osmium combines with mercury; the amalgam is decomposed by heat the mercury volatilising, and the osmium remaining behind in such a fine state of division as to take fire on coming into contact with air; in this condition also it is soluble in nitric acid, but is not so after ignition. In classifying the elements, osmium is usually placed next to arsenic; its equivalent is 99·41.

Oxygen and *osmium* combine in five proportions, forming:—

1. Protoxide of Osmium	OsO
2. Sesquioxide of Osmium	Os_2O_3
3. Binoxide of Osmium	OsO_2
4. Teroxide of Osmium	OsO_3
5. Osmic acid	OsO_5

1. *Protoxide of osmium* (OsO).—When potash is added to a solution of chloride of osmium, the protoxide is precipitated in the state of hydrate (OsO, HO), and is of so dark a green colour as to appear nearly black. This hydrate dissolves slowly in acids, forming dark green coloured solutions, which do not yield crystals by evaporation, but leave green or greenish-brown translucent residues. When the hydrate is heated rather below redness, it loses water. It detonates when heated with certain combustible bodies.

2. *Sesquioxide of osmium* (Os_2O_3) has not been procured in a separate state, but is obtained in combination with ammonia when the binoxide is heated with excess of that alkali; nitrogen is evolved during the operation by the decomposition of a portion of the binoxide and of the ammonia.

3. *Binoxide of osmium* (OsO_2) is formed and precipitated by pouring a solution of carbonate of soda into a saturated solution of bichloride of osmium and potassium. The precipitation takes place gradually, and after separating, by means of hydrochloric acid, a little soda which it retains, it is obtained in a state of purity; it is of a black colour and insoluble in acids.

4. *Teroxide of osmium* (OsO_3), *osmious acid*, is prepared from the terchloride in the same way as the binoxide from the bichloride. Its existence, however, is not perfectly established. A crystalline compound with potash ($KO, OsO_3, 2HO$) appears to exist.

5. *Peroxide of osmium*, or *osmic acid* (OsO_4).—This is a very curious compound, differing remarkably from all the preceding substances. It is obtained whenever osmium is burnt in the air or in oxygen gas, or when the pulverulent metal is heated with hot nitric acid. It is white, very volatile, extremely fusible, soluble in water, and crystallises in colourless transparent flexible needles. It possesses an extremely disagreeable odour, somewhat resembling that of chlorine. It combines with alkalies, forming compounds which are called *osmiates*. When sulphurous acid is added to a solution of osmic acid, it is rendered yellow, orange, brown, green, and blue, dependent upon the extent to which the deoxidisement is carried on. It stains the skin, is acid and poisonous.

Osmium and *sulphur* form four sulphides. They are produced on passing sulphuretted hydrogen through the hydrochloric solutions of the oxides. They much resemble the latter in constitution.

Osmium and *chlorine* form four chlorides, namely, *protochloride of osmium* ($OsCl$), which sublimes in green needles on passing chlorine over osmium heated in a long tube; *sesquichloride of osmium* (Os_2Cl_3), known only in combination with chloride of ammonium; *bichloride of osmium* ($OsCl_2$), formed by excess of chlorine in the preparation of the protochloride, but crystallising farther from the source of heat, and is red instead of green; and *terchloride of osmium* ($OsCl_3$), also known only in combination with chloride of ammonium.

Osmium and *nitrogen* form *osmiamic acid* (Os_2NO_5), according to Gerhardt, or *osmanosmic acid* (OsN, OsO_4), according to Fritzsche and Struve. It separates as a yellow crystalline powder on adding caustic ammonia to a solution of osmic acid in potash.

The remaining compounds of osmium have not been satisfactorily studied. They are all characterised by giving fumes of osmic acid, when heated with carbonate of soda on platinum foil in the blowpipe flame, and the fumes are recognised by their odour. Osmic acid also imparts luminosity to the flame of alcohol.

OSMOSE. The phenomena of liquid diffusion [Diffusion] become more complicated when the two liquids are separated by means of a porous diaphragm, because in such case there is adhesion between the liquids and the material of the diaphragm: nevertheless the liquids will mingle together in opposition to gravity. For example, if a funnel, furnished with a long narrow stem, and a piece of moistened bladder tied over its mouth, be filled with spirit of wine or with syrup, and be placed in a shallow vessel of water, the liquid will in a few hours rise in the tube, and even overflow. In this case there is a greater adhesion between water and the membrane than between spirit and the membrane; hence the water in contact with the lower surface of the membrane rises into it by capillary attraction, and gains the upper surface where diffusion of the water through the spirit sets in, and is promoted by the adhesion existing between the two liquids. In this way the liquid within the funnel increases in bulk, and fills and even overflows the tube. This flowing in of the liquid was termed by Dutrochet *endosmosis*, from *ενδον* "inwards," and *ωσμος* "impulse." While this force is acting from without inwards, a small quantity of spirit is passing out into the water below, which process of flowing out is termed *exosmosis*. If two other liquids be selected the phenomena will be produced, provided one liquid adhere to the bladder more perfectly than the other, and the two liquids have a certain degree of adhesion for each other.

Graham ('Phil. Trans.,' 1854) has investigated the subject, which is one of great interest, physiologically as well as chemically. The instrument used in his experiments is termed an *osmometer*: it is formed of a bell-glass of five or six ounces, having a plate of perforated zinc over its open mouth, and outside this is securely tied a piece of fresh ox-bladder with the muscular coat removed; or else an artificial membrane of calico soaked in white of egg, and dipped in boiling water to coagulate it. A tube $\frac{1}{10}$th of the diameter of the mouth of the bell-glass, is fitted into an aperture at its top, and is graduated into millimetres, each degree being about $\frac{1}{25}$th of an inch. A rise or fall in the liquid in the tube, amounting to 100 millimetres, represents the entrance or removal of a stratum of liquid 1 millimetre thick over the surface of the membrane. The saline solution to be examined is placed in the jar, until it stands at a fixed mark in the tube. The jar is then placed on a tripod within a tall cylinder, into which distilled water is poured up to the level of the liquid in the tube, and this level is maintained during the experiment by adding or removing water from the outer jar. In this way it was found—1. That neutral organic substances, such as urea, gum arabic, sugar of milk, gelatine, and salicin, exert little or no osmotic action. 2. That strictly neutral salts, such as sulphate of magnesia, chloride of sodium, and chloride of barium, have no peculiar osmotic action, but follow nearly the same rate of diffusion as when no diaphragm is used. 3. That alkaline solutions, especially those of potash and soda, produce energetic osmotic results: dilute solutions containing not more than 2 per cent. of the salt, answered best; but the effect was observed when 1 part of the salt was contained in 1000 of water; and while a large bulk of water entered the osmometer, only a minute portion of the alkaline salt escaped into the water of the outer jar. Thus, with a solution of carbonate of potash (1 part salt to 1000 water) in the osmometer, the liquid rose in the stem 192 divisions in five hours, and for each grain of carbonate of potash that was diffused into the outer cylinder more than 550 grains of water entered the osmometer. When, however, a solution containing 1 per cent. of carbonate of potash was used, only 63 grains of water entered the osmometer for each grain of carbonate that passed into the outer cylinder. When the liquid rises in the osmometer it is termed *positive osmose.* 4. That dilute acids and solutions of acid salts produce a current in the opposite direction, so that the column falls in the stem; this is known as *negative osmose.* Osmose is remarkably shown in salts which admit of division into a basic salt and a free acid. Acetate of alumina, nitrate of lead, chloride of zinc, and the salts of the sesquioxides of chromium and iron are good examples. In such cases the acid diffuses outwards, and the inner surface of the membrane remains in a basic condition while the outer surface is acid—conditions which are highly favourable to rapid positive osmose. 5. That in all cases of osmotic actions (except where alcohol and cane-sugar are concerned) the material of the diaphragm is chemically acted on, and if the diaphragm be made of a material not capable of decomposition by the liquids, such as gypsum, unbaked clay, tanned leather, compressed charcoal, although sufficiently porous, there is little or no osmotic action. The most favourable cases are those in which the chemical action on the diaphragm is different on the two sides both in degree and kind, as when one surface is acid and the other alkaline. 6. That two salts, when mixed, often exert an osmotic action very different from what they exercise separately. Thus, sulphate of potash has a feeble positive osmose, but a very minute addition of carbonate of potash increases its osmotic force fivefold, and a minute trace of hydrochloric acid arrests it. Chloride of sodium also reduces osmotic action in other salts.

The osmotic force must be distinguished from Diffusion; for in the latter case, if a saline solution were in the interior reservoir, liquid salt particles would ooze through the membrane, and a certain quantity of water would flow back and take their place; but if this were a case of diffusion the water would not be more than five or six times the weight of the escaping salt, whereas the water entering the osmometer may exceed the weight of the escaping salt 100 times or more. Nor can osmose be identified with capillarity. [Capillary Attraction and Repulsion.] Many of the saline solutions which exhibit the greatest osmose are not distinguishable in capillary phenomena from pure water. The force of the osmotic current may also be measured in the following manner, devised by Liebig:—Close the open end of the short limb of a glass syphon by means of a piece of bladder; pour a little mercury into the bend of the tube, and fill the shorter limb with the saline liquid. Immerse the bend of the tube and the membrane in water, leaving the extremity of the longer limb open; and as the water enters the tube the mercury will rise in the longer limb, and when the column reaches a certain height the two liquids will intermingle without change of volume. The length of the column which has been raised above the level of the surface of the mercury is to be measured, and this, when compared with the lengths of the columns obtained with other liquids, will give a comparative measure of the osmotic force in each case. Thus it will be seen that chemical affinity (shown by the action on the diaphragm) is converted into motive power, capable of numerical expression. It seems most probable that in the animal system there is an arrangement by which motive power is obtained from the decomposition of the tissues. All parts of living structures are in a condition of incessant change, decomposition, and renewal. It may one day be demonstrated that the osmotic injection of fluids is the associating link between muscular movement and chemical decomposition.

The flow of liquids through capillary tubes presents phenomena closely connected with diffusion. They are well discussed in M. Poiseuille's memoire ('Annales de Chimie,' 3 serie, xxi). They are also stated in a briefer form in Professor Miller's 'Elements of Chemistry,' part i., 2nd edition, 1860, where the following remarks occur:—"Osmotic phenomena are constantly going on both in plants and in animals; for in their tissues liquids of very different natures, sometimes acid, still more often alkaline, are circulating through vessels necessarily constructed of flexible and porous materials, and in the economy both of the vegetable and of the animal creation such actions are of the highest importance to the due performance of the vital functions. In fact, we as yet know not how intimately the entire processes of absorption, nutrition, and secretion are connected with the operations of liquid diffusion and of endosmosis."

OSSEIN. A peculiar kind of gelatin found in bones, horns, &c. It is insoluble in cold water, dilute acids, alcohol, and ether; but gradually soluble in boiling water, forming a jelly on cooling.

OSSIFICATION is the formation of bone. This process occurs naturally in the formation of the skeleton of man and the higher animals. [Bone, Nat. Hist. Div.] It also occurs in the reproduction of new bone after the destruction or loss of old bones. [Fracture.] Ossification occurs as an unnatural or morbid process. It is observed in several tissues of the body. It is most frequent in the cartilages of the ribs, in which it almost constantly occurs in advancing years. In most persons bone begins to form in these parts after the fiftieth year; it sometimes commences between the ages of thirty and forty, but is often delayed to a much later period; and Harvey relates that in the body of Thomas Parr, who died in his 153rd year, the cartilages of the ribs were still flexible and soft. The change is generally earlier in men than in women, and it affects the cartilage of the first rib sooner than the rest.

Next to the cartilages of the ribs those of the windpipe are most liable to become osseous. Ossification of the cartilages of the ear, nose, and Eustachian tube is, on the contrary, extremely rare, and in the few cases in which it occurs it is not particularly connected with old age. The cartilages of the moveable joints never ossify.

The tendinous tissue is that which, next to the cartilaginous, is most subject to ossification. This change is not uncommon at the insertion of the tendons of muscles that are much exerted, and in the ligament of some fixed or scarcely moveable joints. Small pieces of bone are also not unfrequently formed in the dura mater; and these are one of the sources of incurable epilepsy. Bone is also sometimes formed in the fibrous coats of the spleen and liver.

Ossification occasionally takes place in the false membranes produced by acute inflammation of the pleura, and more rarely in those of the pericardium; and it is a common process in the adhesions which form between the heads of bones exposed by ulceration of their cartilages, producing the most fixed kind of anchylosis of the joints.

A few remarkable cases are recorded of ossification of the muscles. There is a skeleton in the museum of the College of Surgeons in London, in which it has taken place to such an extent that nearly all the bones must have been immovably fixed by the transformation of the tissues by which, in the healthy state, they are moved. In equally rare cases the crystalline lens, the vitreous humour, and some other parts, are found converted into bone.

In all these examples the material formed exactly resembles true bone in its minute structure and chemical composition. In other cases, as in ossification of the heart and arteries, the substance deposited is composed of carbonate and phosphate of lime, as bone is, but its particles have no definite arrangement. That which is called ossification of the heart is not an affection of the proper substance of that organ, but of its valves, in which earthy matter is sometimes deposited, so as to render them stiff and unyielding, and destroy the pliancy which is necessary for the performance of their functions. A deposition of earthy matter in any part of the substance of the heart itself is very rare. [Heart, Diseases of.]

The disease named ossification of the arteries consists in the deposition of plates or rings of hard earthy substance in their middle elastic coats. This deposition is preceded by that of a peculiar soft or opaque yellow substance, which becomes gradually hardened. The deposition of this yellow substance in the large arteries is so common that it is very rare to meet with the body of an adult in whom it has not taken place to a greater or less extent; and it not unfrequently commences in early childhood. The change to earthy matter does not commonly take place before the thirtieth year, and is very general after the sixtieth. The roughness and irregularity in the circulation which it produces in the large arteries and the ulceration of their lining membranes which often accompanies it, frequently produce serious symptoms. The same changes are frequent in the arteries of the legs, and the obstruction to the circulation which they produce generally gives rise, if life is sufficiently prolonged, to the affection called gangræna senilis. [Arteries, Diseases of.]

OSTRACISM, the name for a singular institution existing for some time among the Athenians. When any man became conspicuous by wealth or by power, from whatever source derived, and was in consequence thought likely to conceive plans of ambition dangerous to the public peace and the stability of the existing form of government, this institution enabled the Athenian people to send him for a time into exile, and thus rid themselves of the danger which they dreaded. It was done as follows:—When the occasion was thought to require it, a day was fixed at an ordinary meeting of the Athenian people, for the purpose of holding an *ostracism.* On that day a part of the market-place (ἀγορά) was railed in, ten different approaches being left to the part thus railed in. There was thus one approach for each of the ten Athenian tribes. By these approaches the citizens, distributed according to their tribes, entered the space within the rails, and there deposited, in urns provided for the purpose, their shells or bits of earthenware (*ὄστρακα, ostraca,* whence the name *ostracism*), marked with the name of the person whom they respectively thought it desirable to banish. The nine archons, together with the Proëdri and Prytanes, superintended, seeing that everything was done properly, and in the end counting the votes. First of all they counted the gross number, which it was necessary should be above six thousand, else there was no valid ostracism. (Heumann, 'De Ostracismo Atheniense.') If there were found to be six thousand votes, then they proceeded to count the numbers against different individuals; and the individual against whom there was the greatest number of votes was sentenced to ten years' banishment, or (changing the phrase) was *ostracised.* He was then obliged to leave Athens within ten days after the sentence, and unless a vote of the people recalled him before the expiration of that time, to stay in exile for ten years; a period subsequently reduced to five years. The goods of the ostracised person were not confiscated, neither was ostracism considered in the light of a punishment or accounted a disgrace. It passed for what it was,—a declaration of superior wealth, of superior influence, sometimes indeed of superior virtue, whose ascendancy the state dreaded.

It is well known that Aristides the Just was one of those on whom ostracism was inflicted. The story told by Plutarch of his writing down his own name for ostracism is also well known.

Ostracism was introduced into Athens by Cleisthenes after the expulsion of the Pisistratidæ (Ælian, 'Var. Hist.,' viii., c. 24); and Cleisthenes was the first victim. Themistocles, Cimon, Alcibiades, Thucydides, were all numbered among the ostracised.

As to the merits of such an institution as ostracism, there cannot be any great difference of opinion. That must be a bad form of polity which needs it, though under a bad form of polity it may be itself a good. The first object of the statesman is to construct a government proof against the wealth and power arising from the ordinary course of social development: if he fails in this, he must defend the government, even at the expense of partial evil. The Athenians took care to mitigate the severity of the banishment, so far as they could consistently with the object of it. "Though this institution," says Montesquieu, "may be so far a condemnation of popular governments, yet it is, on the other hand, well fitted to prove their mildness; and we should have perceived this, were it not that, exile being with us always a punishment, we have been unable to separate the idea of ostracism from that of punishment." ('Esprit des Lois,' book xxi., chap. 17.) Mr. Grote ('History of Greece') calls it "a wise precaution," as preventing the excesses of partisanship by showing decisively the sense of the majority of the community, and less likely to lead even the victorious party to any infringement of the constitution.

A similar institution is said to have prevailed in Argos, Miletus, and Megara. At Syracuse also it prevailed, and there bore the name *Petalism*, leaves (πέταλα) being used on the occasion of voting, instead of shells.

OSTROGOTHS, or Eastern Goths, a division of the great Gothic nation, were settled in Pannonia in the 5th century of our era, whence they extended their dominion over Noricum, Rhætia, and the Illyricum. [GOTHS.] About the year 482 or 483 A.D., their king Theodoric was serving as an auxiliary under the emperor Zeno, and distinguished himself in Syria. On his return to Constantinople, Theodoric, according to the statement of the historian Evagrius, fearing Zeno's jealousy of his success, retired into Pannonia in 487, where he collected an army, and in the following year marched into Italy, with all his tribe, men, women, and children, and, as appears, with the consent of Zeno himself, who wished to remove the Ostrogoths from his territories. He defeated Odoacer in various battles, took him prisoner, and some time after put him to death. Upon this event, Theodoric sent an ambassador to Anastasius, the emperor of Constantinople, who sent him in return the purple vest, and acknowledged him as king of Italy. It appears that both Theodoric and his predecessor Odoacer acknowledged, nominally at least, the supremacy of the Eastern emperor. For the rest of the history of the Ostrogoths see THEODORIC [in BIOG. DIV.], who established his dynasty over Italy, which is generally styled the reign of the Goths in that country.

OTHYL, COMPOUND OF. (See col. 28.)

OTHYL, HYDRIDE OF. (See col. 23.)

OUNCE. [POUND.]

OUTLAWRY. This term, which is derived from the Saxon *Utlagh* or *Uthlagh*, signifies an exclusion from the protection of the law. In English law it is a punishment consequent upon a flight from justice, or a contumacious neglect or refusal to appear and answer for a criminal transgression, in obedience to the process of a court of competent jurisdiction. By the laws of the Anglo-Saxons, continued after the Conquest, an outlaw, who was also called *laughlesman* (lawless man) and *frendlesman* (friendless man), lost his *liberam legem*, and had no protection from the frankpledge in the decennary in which he was sworn. A boy under twelve years of age, not being sworn to his law in the decennary, could not be outlawed; and for the same reason a woman who contumaciously refused to appear could not be outlawed, but was said to be *waived* (derelicta), and incurred the same penal consequences as an outlaw.

For centuries after the Conquest an outlaw was said "Gerere caput lupinum," and might be lawfully killed by any one who met him. It is stated in the 'Mirror' (cap. iv. sec. 4) to have been the custom for those who slew outlaws or wolves to "carry the heads to the chief place of the county or franchise, and there to receive a demi-mark from the county for each head, whether of an outlaw or a wolf." The 'Mirror' is a book of doubtful antiquity and authority, and this story of the reward for the heads of outlaws is probably fabulous, or at all events an exaggeration of the fact. Bracton (lib. iii., cap. 18), declares that an outlaw "might be killed by all, especially if he defended himself or ran away, so that it was difficult to take him; but that when once taken, his life and death were in the king's hands; and if any man then killed him, he must answer for it as in the case of any other homicide." That this practice and law prevailed in his time is further proved by another passage (c. 14), in which he says that a man who has been outlawed, but has become "inlagatus," or restored to his law by a pardon from the king, should take care always to "carry his pardon about with him wheresoever he may go, and have it ready in his hand to show, lest peradventure some person, not knowing that he has obtained the king's grace, should slay him as an outlaw." Fleta (lib. i., cap. 27), mentions the same law, and justifies it: "Utlagatus et waiviata capita gerunt lupina, quæ ab omnibus impunè poterunt amputari; merito enim sine lege perire debent qui secundum legem vivere recusant." Lord Coke says, "In the beginning of the reign of Edward III. it was resolved by the judges, for avoiding of inhumanity and effusion of Christian blood, that it should not be lawful for any man but the sheriff only (having lawful warrant therefore) to put to death any man outlawed, though it were for felony; and if he did, he should undergo such punishments and pains of death as if he had killed any other man; and so from thenceforth the law continued until this day." For this fact he refers to the 'Year Book,' 2 Ass. pl. 3. The 'Year Book' however, as cited, and another report of the same case in Fitzherbert's 'Abridgement,' tit. Corone, 148, contain no such resolution, and the case from which it is obvious that Lord Coke derived the above statement, is clearly an authority to show the continuance of the old practice. A man being arraigned for homicide objects to answer because the person with whose death he was charged had been outlawed for felony. The judges at first certainly appeared to think that it was not lawful for any one to kill an outlaw unless it were upon his resisting a bailiff who should attempt to arrest him. But after argument, they said they "must send to the chancery to inquire if the deceased had a charter of pardon, and search their own rolls to see if his outlawry has been reversed;" and they admitted the prisoner to bail in the mean time, telling him that if they found that there had been no pardon and no reversal of the outlawry, he would not be called upon to answer. This case therefore seems to show that Lord Coke prematurely claimed for the judges in the reign of Edward III. the merit of abolishing this barbarous practice; indeed so late as the reign of Philip and Mary, Staundforde, in his 'Pleas of the Crown,' mentions the above case, and speaks of the law upon this subject as doubtful. However, though the technical quality of homicide so committed may have been questionable, there is no doubt that the practice of killing outlaws like wild beasts had ceased long before Staundforde's time.

The consequences of outlawry are the forfeiture of goods and chattels universally. Where it takes place upon a prosecution for *treason or murder*, it amounts to a conviction and attainder of the offence charged, and therefore all the outlaw's real property, as well as his personalty, is forfeited. Where it takes place upon criminal prosecutions for other offences, or upon civil actions, the profits only of the defendant's lands are, during his life, forfeited to the crown. The outlaw, having neither the privilege nor protection of the law, is incapable of maintaining any action; at common law he cannot be a juror, as he is not "liber et legalis;" and he is expressly excluded from acting as such by stat. 6 Geo. IV., c. 50, sec. 3.

The consequences of outlawry being so highly penal, the law has at all times been careful that no person shall be outlawed without sufficient notice of the process of the court, and without satisfactory proof of his contumacy. He must be called or *exacted* in five successive county courts, or in five successive hustings, if in London; if he renders himself, the sheriff takes him. But if he does not appear at the fifth county-court or husting, judgment of outlawry is forthwith pronounced by the *coroners*, who are the judges for this purpose in the county-court, and by the recorder if the proceedings are in London (Co. Litt., 288 *b*; Dyer, 223 *a*, 317 *a*). Upon this return a writ of capias utlegatum may be issued into any county to arrest the defendant, and other process follows against his property. As an additional security that a man shall not be outlawed without notice of the process to which he is required to appear, the sheriff must make three proclamations of him in notorious places in the county a month before the outlawry shall take place.

An outlawry may be reversed by writ of error, in which the party may avail himself of errors either of law or fact; the slightest mistake in any part of the proceedings being sufficient to avoid the outlawry. It was formerly necessary to procure a pardon from the crown, by which the outlaw was restored to his law, and became "inlagatus." It has long been the usual course for the courts to reverse outlawries upon motion, justice being thus expedited and expense saved.

OUTWORKS, in fortification, is the term applied to the various works constructed outside the enceinte of a fortress. These may be either temporary, to take advantage of the ground and enfilade a besieger's works, or they may be permanent works established on heights and commanding ground which it is necessary to occupy.

OVAL, or as the name imports, egg-shaped, is the name given originally to such a form as the section of an egg presents, round, but not circular. In mathematics it has received some extension of meaning. Any curve, or isolated branch of a curve, which returns into itself, would be called an oval; perhaps even a figure of eight would receive the name.

The curve having for its equation

$$y=\sqrt{x(x-a)\ (x^2-b)}$$

(a and b being positive, and a less than b) has an oval extending from $x=0$ to $x=a$: but there is no curve whatever from $x=a$ to $x=b$, or from $x=-b$ to $x=0$. If a be small, the dimensions of the oval are small: and when $a=0$ the equation becomes

$$y=x\sqrt{(x^2-b^2)}$$

in which the oval has become a point (the origin), and is a *conjugate point* [CURVE], an isolated point which is not on any continuous branch.

Some conjugate points have none but imaginary values of $dy:dx$, some have one or more finite values. Thus when $y=x\sqrt{x^2-b^2}$, there is a conjugate point at the origin, and $dy:dx$ is then imaginary: but when $y=x^2\sqrt{(x^2-b^2)}$ there is also a conjugate point at the origin, but $dy:dx$ is 0. The meaning seems to be (as far as we can judge from a few instances) that when the oval during its diminution, has axes which preserve a finite ratio to one another, so that its tangents fall in all directions, the ultimate value of $dy:dx$ is imaginary. But when one of the axes diminishes without limit as compared with the other, so that, except near the ends of that axis, the tangents tend to assume one direction, there is an ultimate value of $dy:dx$ which defines that direction. If our surmise be correct, a double or triple value of $dy:dx$ at the conjugate point would indicate the evanescence of a star-shaped oval, or of one which tends to assume that form as it diminishes. But this, with other points relating to the singular values of algebraic functions, has yet to be fully considered.

OVALBUMEN. A name given to the albumen of the hen's egg to distinguish it from the albumen of blood (*seralbumen*) which differs somewhat from the former.

OVARIAN DROPSY. [WOMB, DISEASES OF.]

OVATION. [TRIUMPH.]

OVERSEER, an officer appointed by justices of counties or boroughs, for parishes under the 43 Eliz., 2, and for townships under the 13 & 14 Car. II., 12. They cannot be less than two nor more than four for one parish or township. Churchwardens are ex-officio overseers of the poor. The duties of a paid assistant-overseer are identical with those of an overseer, so far as they may be specified in the warrant of justices, appointing the former under the 59 Geo. III , 12, s. 7, on account of the amount of the population, the extent of the parish, or other difficulties, rendering the office of overseer onerous and troublesome. Before the passing of the Poor-Law Amendment Act, (4 & 5 Will. IV., c. 76) it was the business of an overseer as well to expend as to make out and collect the poor-rates. Where no select vestry existed, he was judge of the necessities of applicants for parochial relief, an appeal in case of refusal lying before magistrates in petty sessions. For an account of the abuses which arose from the trust the law formerly confided to overseers, see the article POOR-LAW, and the report of the commissioners for inquiring into the administration of the poor-law, published in 1834.

The 4 & 5 Will. IV., c. 76, commonly known as the Poor-Law Amendment Act, limited the authority of an overseer of the poor, by transferring to a board of guardians such portion of his duties as related to ascertaining fit objects for parochial relief, the amount of relief to be given, and the manner of giving it. With such services he has now little to do. His first business on entering upon his office is to obtain from his predecessors the parish books and documents and to collect outstanding arrears of poor rates, if any. If he have reason to believe that any demand for money will be made upon him by the guardians, he should forthwith make a poor rate, which must be signed by a majority of the parish officers, allowed by the justices and published. A poor rate is due from every person assessed, immediately after it is published, and if any person refuse to pay the rate, after a proper demand made upon him, the same may be enforced by distress and sale of the goods of the defaulter. If there should be no goods to distrain upon, the defaulter may be committed to prison for three months, unless the rate be sooner paid. The rate may be appealed against at the next special sessions, after it is made, on the ground of inequality or incorrectness; and if the overseers have a good defence, it will be their duty to defend the rate at the sessions. If they have no valid defence, they should at once consent to the rate being quashed or amended by the justices, as the case may require. If it should be quashed they should then proceed to make a fresh rate, avoiding the errors which led to the quashing of the former rate.

An overseer is only to give relief to the poor "in any case of sudden or urgent necessity;" and, as soon as he is able, is to report to the relieving-officer his having given such relief. The relief may not be given in money, but only in articles of absolute necessity. At the end of each half-year the overseer will receive a notice from the district auditor, to attend him in order that his accounts may be examined and audited. He should take with him to the audit all his parish books, letters, and papers, to any of which reference may possibly be made. He is to manage and collect the rents of parish property, and he has various duties cast upon him by statute and by the general consolidated order of the Poor-Law Board, in connection with the annual election of a guardian, or guardians, for his parish. Those duties will be found fully set out in Mr. Glen's collection of Poor-Law statutes and Poor-Law Board orders; and are much too voluminous to come within the limits of the present article.

With regard to registration, his business is as follows:—On the 20th of June in each year, he will affix on the church door a notice, directing fresh claimants for votes to make formal claim in writing to the overseer on or before the 20th of July. His next step is to make out for each parish an alphabetical list of the names of all persons already in the register, together with those of all claimants. This list must be completed by the last day of July, and affixed on the church or chapel, and, if there be no church or chapel, in some conspicuous situation, on the two first Sundays in August. He must give copies of this list for a reasonable payment, if required. On or before the 25th of August, objections to votes may be received. An alphabetical list of objections is to be posted, as before, on the two Sundays next preceding the 15th of September. When the revising barrister holds his court, it will be the duty of the overseer to attend. His expenses arising from his duties connected with registration are defrayed from the poor-rate. So far with regard to registration of county voters. Overseers of a parish situated in a borough, by the last day of July, without any claims being made, must make an alphabetical list of persons having a 10*l.* qualification in respect to premises situated in their parish. A similar list of freemen must be made where freemen are entitled to votes. These lists must be fixed as above. Claims from persons omitted and objections are received on or before the 25th of August, and lists of these claims, &c., are to be posted on the two Sundays next preceding the 15th of September. The forms according to which overseers are to frame their notices are to be found in the acts of parliament whence their obligations arise. The limits of this article do not admit of the duties of an overseer of the poor being further enlarged upon; the reader is therefore recommended to consult the publications of the learned gentleman before referred to, which are the standard works on the subject.

OVERTURE (*Ouverture*, Fr., *Sinfonia*, Ital.), a musical composition for a full instrumental band, introductory to an oratorio, opera, or ballet. An overture is a kind of musical prologue, and, as such, ought to be in good keeping with the piece which it ushers in; though in most instances but little attention has been paid to the character of this important feature of the melodrama. There are some exceptions, however, as in the fine overtures to 'Don Giovanni,' 'Der Freischütz,' and 'A Midsummer-Night's Dream,' all of which fully prepare the mind—in so far as inarticulate sounds can prepare it—for the romantic stories and supernatural agency of the following scenes.

The overture originated with Lully [LULLY, in BIOG. DIV.], whose compositions supplied many of the early Italian operas with an opening instrumental piece. And indeed Handel himself imitated to a certain extent the overtures of the French composer; though in this case, as in every other of the kind, he improved whatever he touched.

Some good observations on the position and office of the overture will be found in an Essay by M. Fétis, entitled 'La Musique mise à la portée de tout le monde.' The author characterises Mozart's overture to 'Zauberflöte,' as a "chef-d'œuvre inimitable, qui sera eternellement le modèle des overtures et le désespoir des compositeurs."

OWNERSHIP. [PROPERTY.]

OXALAMYLIC ACID. [OXALIC ACID.]

OXALATES. [OXALIC ACID.]

OXALHYDRIC ACID. [SACCHARIC ACID.]

OXALIC ACID ($HO, C_2O_3+2Aq.$) This acid was discovered by Scheele, in 1776. It occurs in several plants, as in the wood sorrel (*Oxalis acetosella*) hence the name *oxalic*, and in common sorrel (*Rumex acetosa*). In the juice of these plants, and in the roots of rhubarb, bistort, gentian, &c., it is combined with potash; in several kinds of lichens, it is found in union with lime. It occurs as a mineral compound in combination with oxide of iron, called *Humboldtite*. It is an ingredient also of several urinary calculi.

Oxalic acid may be obtained by several processes: first, by decomposing the natural superoxalate of potash, or salt of sorrel, by means of acetate of lead, sulphuric acid, &c.; but it is best obtained by heating organic matter, such as sugar, potato starch, or even sawdust, with nitric acid in a retort. Having been first obtained from sugar it received the name of *saccharine acid*. Indeed most organic compounds which contain much carbon and no nitrogen, may be converted into oxalic acid by the action of nitric acid; hydrate of potash, in some cases, produces similar results, and this process applied to sawdust now yields much of the oxalic acid used in commerce. When nitric acid acts upon sugar or starch or sawdust, it is decomposed, and yields nitric oxide gas in great quantity; the oxygen of the decomposed acid uniting with the carbon of the vegetable matter, converts it into oxalic acid: the crystals first obtained are to be dissolved in water and re-crystallised to render them perfectly pure.

Oxalic acid crystals are prismatic, colourless, and transparent; the primary form is a right rhombic prism. Their taste is extremely sour, and they are very poisonous. When dissolved in 200,000 times their weight of water, the solution reddens litmus paper. Exposed to a dry air, oxalic acid effloresces, losing water of crystallisation; it dissolves in 15 parts of water at 50°, and in 9 parts at 60°; at 212° it melts in its water of crystallisation; it is soluble also in alcohol, but less so than in water.

Oxalic acid is usually considered to be monobasic, but most of its properties are those of a member of the dibasic series.

No means have yet been discovered of forming oxalic acid by combining carbonic oxide and carbonic acid; but when oxalic acid is heated with sulphuric acid, it resolves into these substances entirely, and in the proportions stated, the water which it contains combining with the sulphuric acid.

Oxalic acid contains water that cannot be totally expelled by heat; the acid, unless combined with a base, always retaining one equivalent.

Oxalic acid is to a certain extent volatile, and Mr. Faraday has shown that sublimation takes place even at common temperatures; at 212° the volatilisation is much more considerable; and when deprived of two-thirds of its water of crystallisation, it sublimes rapidly and without decomposing; the sublimed acid is crystalline, and contains one equivalent of water.

When oxalic acid retaining the whole of its water of crystallisation is suddenly heated up to about 300°, it yields carbonic acid, carbonic oxide, formic acid, and water.

Oxalic acid forms compounds with bases, which are termed *oxalates*, and of these we shall describe some of the more important.

Oxalate of ammonia. [AMMONIUM, *oxalate of ammonia.*]

Binoxalate of ammonia may also be formed, but it is not of importance. When binoxalate of ammonia is heated it yields *oxamic acid* ($C_4H_3NO_6$).

Oxalate of potash ($KO, C_2O_3, Aq.$)—Oxalic acid forms three salts with potash: the *neutral oxalate* is obtained by saturating the acid with the alkali. It crystallises in flat rhombic crystals, which are so very soluble in water, that even when cold the latter takes up half its weight. When a solution of oxalic acid is added to this, precipitation of a less soluble supersalt occurs.

Binoxalate of potash ($KO, HO, 2C_2O_3 + 2Aq.$) may be prepared either by dissolving the requisite quantities of acid and alkali in water, or, as above mentioned, by adding oxalic acid to the neutral salt. It forms small rhombic crystals, which have a bitter taste and an acid reaction; they are soluble in about 10 times their weight of cold water. This salt, mixed with the quadroxalate, exists in *oxalis acetosella*, and they constitute the compound know by the name of the *salt of sorrel*, or *salt of lemons*, employed for removing ink-spots.

Quadroxalate of potash ($KO, 3HO, 4C_2O_3 + 4Aq.$) may be formed by digesting the binoxalate in hydrochloric acid, which taking half the potash, the remainder becomes quadroxalate; or by saturating carbonate of potash with oxalic acid, and then adding three times the weight of oxalic acid already used. The crystals are prismatic, and are as little soluble in water as those of the binoxalate.

The oxalates of potash are all converted by a red heat into carbonate of potash; their composition was first ascertained and pointed out by Dr. Wollaston as affording one of the most remarkable series of proofs of the doctrine of multiple proportions.

Oxalate and binoxalate of soda may be formed, but they are not employed.

Oxalate of lime ($CaO, C_2O_3, 2Aq.$) is a very insoluble compound, and hence oxalic acid and lime, with certain restrictions, are used as tests of each other's presence. Baryta and strontia also form insoluble compounds with oxalic acid. The remaining metallic oxalates of importance are noticed under the respective metals.

Oxalic ether, or *oxalate of ethyl* $\left(C_4O_6\left\{\begin{matrix}C_4H_5O\\C_4H_5O\end{matrix}\right.\right)$ is best obtained by allowing a slow stream of absolute alcohol to flow into a retort containing oxalic acid in a state of fusion, and from which the water has been mostly driven off. The distillate is washed with water, in which it is only slightly soluble, and finally dried over chloride of calcium. Its specific gravity is 1·0929; vapour density, 5·1; boiling point, 363·2° Fahr. It is miscible with alcohol or ether. Potash and soda decompose it, and ammonia converts it into *oxamide* Potassium transforms it into carbonic ether with evolution of carbonic oxide.

Amyloxalic acid, or *oxalamylic acid* $\left(C_4O_6\left\{\begin{matrix}C_{10}H_{11}O\\H\ O\end{matrix}\right.\right)$ is formed on treating amylic alcohol with excess of oxalic acid.

Tests for oxalic acid.—The best is the production of a white precipitate (oxalate of lime), with any soluble calcium salt, insoluble in acetic acid, but soluble in hydrochloric acid.

OXALIC ACID, the most highly oxygenated of all the vegetable acids, is also the most rapid and certainly fatal of any which are capable of being crystallised. As the crystals are not unlike those of the sulphate of magnesia, or Epsom salts, mistakes between the two are of very frequent occurrence. Being likewise much used in the arts, and commonly known by the name of *acid of sugar*, it is taken either accidentally, or under the supposition that it is akin to sugar, and therefore pleasant and innocent.

To prevent confusion of the crystals of this formidable acid with those of the sulphate of magnesia, it has been proposed that the former should be coloured while in the course of preparation, an expedient which has not been adopted. But on the other hand, the crystals of Epsom salts have been manufactured of a different shape by a peculiar process of crystallisation. The taste is very different, a solution of oxalic acid being intensely sour, while that of sulphate of magnesia is extremely bitter. Attention to this point, in previously tasting a small quantity, may prevent very serious casualties. Oxalic acid not only acts with violence, but produces nearly the same effects to whatever texture of the body it is applied. The concentrated acid, if taken in considerable dose, may cause death in from two to twenty minutes. "After death the stomach is found to contain black extravasated blood, exactly like blood acted on by oxalic acid out of the body; the inner coat of the stomach is of a cherry-red colour, with streaks of black granular warty extravasation; and in some places the surface of the coat is very brittle and the subjacent stratum gelatinised. Such are the effects of the concentrated acid. When considerably diluted the phenomena are totally different. When dissolved in twenty parts of water, oxalic acid, like the mineral acids in the same circumstances, ceases to corrode; but, unlike them, it continues a deadly poison, for it causes death by acting indirectly on the brain, spine, and heart. The symptoms then induced vary with the dose. When the quantity is large, the most prominent symptoms are those of palsy of the heart; when less, fits of violent tetanus; and when still less, the spasms are slight or altogether wanting, and death occurs under symptoms of pure narcotism, like those caused by opium." Very few persons have recovered when the quantity taken was considerable. (Christison, 'On Poisons.')

To counteract the very rapid effects of this poison, the most prompt treatment is necessary. Chalk, magnesia, or even the plaster of the room diffused through water, should be given without delay. The other alkalies are improper, as they form soluble salts with the acid, and oxalic acid is an example of a poison which acts through all its soluble chemical combinations. Emetics may be given, if vomiting has not spontaneously taken place; but it is highly inexpedient to give much warm water, as dilution only facilitates the absorption of the poison, and induces its remote but equally fatal effects.

Notwithstanding the formidable properties of this acid, the agreeable cooling effects it displays have led to its employment in the form of lozenges, or in a dilute solution as a refrigerant. Both in this country formerly, and still in France, it is used to quench thirst, and allay the heat of the stomach, which prevails towards the later stages of consumption. But for this purpose citric acid or lemonade is preferable, as well as safer.

Besides the immediate danger from an over-dose, there is yet a remote source of risk which requires notice. Oxalic acid exists in many vegetables, in combination with lime or potass, or free, as in the case of the cicer arietinum. Many of these plants are used in different parts of the world, as salads, on account of their refrigerating quality. Their frequent employment by persons disposed to calculous diseases is highly dangerous, as they give rise to the formation of the mulberry or oxalate of lime calculus, which is not only the most painful of all the stones found in the human kidneys or bladder, but also the most insidious, for, owing to the insolubility of this compound, no deposit or sediment is observed in the urine at an early period, so as to occasion a suspicion of what is taking place. (Majendie, 'On Gravel,' 2nd French edit.) [CICER.]

The now well-ascertained connection between the existence of the oxalic acid diathesis, rheumatism, indigestion, and other painful diseases, renders a popular knowledge of this point of much importance. Not only the free use of some of the vegetables alluded to, but saccharine fruits, sugar, and starch, especially potato starch, give rise to the formation of oxalic acid, and its attendant evils. Rhubarb (*stalks*, not *powder*), sorrels of different sorts, tomatoes, common barberry, should all be avoided by persons prone to rheumatism or stone in the bladder. Hard waters, containing lime, should be eschewed. The excessive use of sugar, either in the ordinary states, or in sweet preserves, is improper. Where any calculus of this sort is detected in the bladder. the employment of bicarbonate of potass in solution gives great relief, by coating the very angular stone with a smooth surface. Its use must not be too long persevered in. (See 'Prout on Stomach and Renal Diseases.')

OXALMETHYLOVINIDE ($C_{10}H_8O_8$). *Oxalate of ethyl and methyl.* An ethereal salt of oxalic acid containing both ethyl and methyl. Its constitution is similar to that of oxalic ether. [OXALIC ACID; *Oxalic Ether.*]

OXALOVINIC ACID. [ETHYL; *Ethyl-oxalic Acid*]

OXALURANILIDE. [URIC ACID.]

OXALURIC ACID. [URIC GROUP.]

OXALYL (C_2O_2). The hypothetical organic radical contained in oxalic acid, which is generally regarded as the hydrated oxide of oxalyl: $\left.\begin{matrix}C_2O_2\\H\end{matrix}\right\}O_2$ or $\left.\begin{matrix}(C_2O_2)_2\\H_2\end{matrix}\right\}O_4$.

OXAMELANILE ($C_{30}H_{11}N_3O_4$). *Melanoximide.* An unimportant organic compound, produced by the transformation of cyano-melaniline under the influence of acids.

OXAMETHANE ($C_8H_7NO_6$). Synonymous with oxamate of ethyl.

OXAMETHYLANE ($C_6H_5NO_6$). Synonymous with oxamate of methyl.

OXAMIC ACID. [OXALIC ACID.]

OXAMIDE ($C_4H_4N_2O_4$). A white pulverulent organic compound produced by the action of heat upon oxalate of ammonia. By the similar action of heat upon the oxalates of the artificial organic bases, a number of bodies analogous to oxamide are produced. The following may serve as examples:—

Dimethyloxamide	$C_8H_8N_2O_4$
Diethyloxamide	$C_{12}H_{12}N_2O_4$
Diamyloxamide	$C_{24}H_{24}N_2O_4$
Phenyloxamide or oxanilamide	$C_{16}H_8N_2O_4$
Diphenyloxamide or oxanilide	$C_{28}H_{12}N_2O_4$

OXAMYLANE ($C_{14}H_{13}NO_6$). Synonymous with oxamate of amyl.

OXANILAMIDE. [OXAMIDE.]

OXANILIC ACID ($C_{16}H_7NO_6$). *Phenyl-oxamic Acid.* An organic acid analogous to the oxamic acid, containing phenyl in the place of one equivalent of hydrogen.

OXANILIDE. [Oxamide.]

OXIDATION. The chemical process of uniting with oxygen; see Combustion; Eremacausis; Oxygen.

OXIDES. [Oxygen.]

OXYACANTHINE. An organic alkaloid of unknown composition, found along with berberine in the *Berberis vulgaris.*

OXYACIDS. [Salts.]

OXYBENZOIC ACID ($C_{14}H_6O_6$). An organic acid isomeric with salicylic acid. It is obtained by the prolonged action of nitrous acid upon benzamic acid. It is a colourless, crystallisable acid, forming salts which are termed *oxybenzoates.*

OXYCHLORIDES. Chemical compounds containing both chlorine and oxygen united with some other element or radical. Thus oxychloride of phosphorus PCl_3O_2.

OXYCOBALTIA. One of the ammoniacal compounds of cobalt. [Cobalt. *Ammoniacal compounds of cobalt.*]

OXYGEN (O), an elementary body, the properties of which are best known and most remarkable in its elastic or aëriform state, in which it is termed *oxygen gas.* The most important discovery of this substance was made by Dr. Priestley, on the 1st of August, 1774; and of his numerous contributions to chemical science, this is at once the most splendid and the most solid, and has rendered his name imperishable.

Dr. Priestley has stated, with his usual candour, that the discovery was also made, quite independently, though later, by Scheele, and he has refuted the unjust claim of Lavoisier to be also one of the discoverers of this element. To this gas Dr. Priestley gave the name of *dephlogisticated air*, Scheele called it *empyreal air*, and Condorcet *vital air*. Lavoisier gave it the name of *oxygen*, from the Greek words ὀξὺς, *acid*, and the root γεν, to *generate*, because he considered it as the sole cause of acidity; this appellation it still retains, although it is now well known that there are acids which do not contain it and alkalies which do.

Dr. Priestley first prepared this gaseous body by heating the binoxide of mercury, then called *mercurius præcipitatus per se*, in an air-jar, over mercury, by means of a lens, and he afterwards obtained it from other substances.

It is now prepared in various ways, according to the purposes to which it is intended to be applied. These ways we shall briefly state and explain, and also describe the production of the gas from the binoxide of mercury, first used by Dr. Priestley.

When mercury is heated, and at the same time exposed to atmospheric air, it is found that the volume of the air is diminished, and the weight of the mercury increased, and that it becomes, during the operation, a red crystalline body, which is the binoxide of mercury, formed by the metal combining with the oxygen of the air.

When this substance is subjected in a retort to a higher temperature than that required for its formation, the affinity between the metal and the oxygen is overcome; the former returns to its metallic state, and the latter to its gaseous form; and if added to the residual atmospheric air, its volume is restored.

If it be quite pure, and the operation be accurately performed, 216 grains (1 equivalent) of binoxide of mercury should be separated by the agency of heat into 200 grains, one equivalent of mercury, and 16 grains, two equivalents of oxygen, measuring 46·7 cubic inches.

By this process then oxygen gas is, though indirectly, obtained from atmospheric air: but there is a natural metallic oxide, the *binoxide of manganese*, which is found plentifully, and which also yields it by the mere application of heat, and the quantity of gas obtained is dependent upon the degree of heat employed; in this case, however, unlike that of the binoxide of mercury, the metal is not reduced. The equivalent of binoxide of manganese [Manganese] is 43·57, consisting of 27·57 of metal and 2 equivalents of oxygen = 16; and when 43·57 grains are heated to moderate redness in a coated glass retort, half an equivalent of oxygen, or 4 grains, measuring 11·67 cubic inches, are expelled, and there remains in the retort an equivalent of sesquioxide of manganese, composed of 27·57 metal and 12 oxygen = 39·57. But if the equivalent of binoxide be strongly heated in an iron retort, it is then converted into red oxide, consisting of one equivalent of metal, and one and one-third of oxygen, while two-thirds of an equivalent of oxygen are expelled, weighing 5·33 grains and measuring 15·56 cubic inches.

Another but less eligible method of obtaining oxygen from the binoxide of manganese, is to heat it with sulphuric acid in a retort; in this case an equivalent of the binoxide = 43·57, loses a whole equivalent of oxygen = 8 grains, or 23·35 cubic inches, and there remain in the retort protoxide of manganese combined with the sulphuric acid, forming protosulphate of manganese. It is to be observed that these statements of the quantities of oxygen procurable from a given quantity of the binoxide of manganese are made on the supposition of its being quite pure, which is hardly ever the case; the binoxide of commerce very commonly contains 20 per cent. of impurity.

Red oxide and binoxide of lead also, when heated, either with or without sulphuric acid, yield oxygen gas, but the quantity obtained is small, and the processes are on several accounts ineligible. When nitrate of potash also is heated to redness, it gives out a considerable quantity of oxygen gas, from the decomposition of the nitric acid; but as it comes over mixed at different periods of the operation with variable quantities of the nitrogen gas of the nitric acid, this is not a method usually resorted to.

The oxygen gas obtained from binoxide of manganese is sufficiently pure for all the usual purposes of experiments intended merely to illustrate the properties of the gas; but when the gas is required for chemical analysis or accurate investigations, it is then obtained from the salt formerly called oxymuriate of potash, but now chlorate of potash.

Chlorate of potash is composed of one equivalent of chloric acid 75·45, and one of potash 47 = 122·45; and when heated in a retort, is resolved into an equivalent of chloride of potassium 74·45, which remains in the retort, and 6 equivalents of oxygen, 5 from the acid and 1 from the potash = 48, which measure 140 cubic inches; so that there is scarcely any other substance which yields so much oxygen gas or of so great purity.

The evolution of the oxygen is greatly facilitated by mixing with the chlorate of potash about one-sixth of its weight either of binoxide of manganese or oxide of copper, and the process thus modified is now almost exclusively used for the preparation of oxygen gas.

Oxygen possesses great power of combination with other elementary bodies, there being only one (fluorine) with which it is not known to combine, either by direct union or indirect chemical action. The compounds to which it gives rise by combining with certain metals, and also indeed with some other bodies, may be classed under the three heads of oxides, acids, and alkalies. There are many bodies which, by a moderate degree of oxidation, become first oxides, and by an increased degree, acids; such substances are charcoal, phosphorus, chromium, &c.: but there is no instance of its forming with different proportions of the same element an acid and an alkali.

The properties of oxygen gas are, that it is devoid of colour, taste, or smell, and being transparent, it is also invisible. It possesses the mechanical properties of common air; it is capable of being respired, and a given volume of it will support life much longer than an equal bulk of common air; on this account the name of vital air was bestowed upon it. It is heavier than atmospheric air, 100 cubic inches at a medium temperature and pressure weighing 34·203 grains, whereas an equal volume of atmospheric air weighs 31·074 grains. It is but slightly soluble in water, requiring about 20 times its bulk for solution. Light has no effect upon this gas; by heat, like all gaseous bodies, it is merely expanded; and electricity is incapable of effecting any change in its properties. Oxygen gas has not been rendered either liquid or solid by the united agency of cold and pressure, and not having been divided into two or more kinds of matter, it is considered as elementary in its nature. Its equivalent, atomic or combining weight, is 8.

It will be proper here to notice the production of oxygen gas by the action of electricity, especially voltaic electricity, which, as is well known, possesses the power of evolving both oxygen and hydrogen from water. Oxygen gas is also evolved by the action of the sun's rays on the moistened leaves of trees, which by this agency decompose the carbonic acid diffused in the atmosphere from various sources, and by combining it with their carbon, flourish and increase in size. When compounds containing oxygen are decomposed by voltaic electricity, the oxygen is evolved in the gaseous state at the anode or positive pole.

The most remarkable property of oxygen gas, and that on account of which it was once called *Fire-air*, is the facility and splendour with which bodies, when previously ignited, burn in it. Substances which do not undergo combustion in the air, will readily do so, and with great brilliancy, in oxygen gas; iron for example burns very readily in it when previously made red-hot. The intensity of the light emitted by burning phosphorus in oxygen gas is such as to be scarcely tolerable.

In conclusion, we may remark, that until after the discovery of this gas nothing was or could be known respecting the nature of the air, of water, or of earth, all of which, formerly reckoned as elementary bodies, are now known to be compound, and to contain oxygen as one of their constituents. It has also thrown great and unexpected light on the nature of combustion and respiration.

The compounds which oxygen forms with metals and other elementary bodies, are treated of in the respective articles on those elements, whether they are oxides, acids, or alkalies. The importance of the oxygen of the air as affecting respiration, vegetation, combustion, and eremacausis, is fully enlarged upon under those words.

OXYGENATED WATER. [Hydrogen.]

OXYHYDROGEN BLOWPIPE. A jet of flame of very high temperature, produced by the combustion of mixed hydrogen and oxygen gases, as described under Drummond Light.

OXYLIZARIC ACID. Synonymous with *purpurin.* [Madder, *Colouring matters of.*]

OXYMURIATIC ACID. [Chlorine.]

OXYNAPHTHALIC ACID. [Naphthalic Group.]

OXYPHENIC ACID ($C_{12}H_6O_4$): *Binoxide of Phenyl; Pyrocatechin; Pyromorintannic Acid.* A colourless crystalline body, obtained by distilling catechu or morintannic acid. It is also contained in wood vinegar.

OXYPICRIC ACID. [Phenylic Group.]

OXYPORPHYRIC ACID. [Euxanthic Acid.]

OXYPROTEIN. [Protein.]

OXYPYROLIC ACID ($C_{14}H_{12}O_{10}$?). An organic acid, formed simultanoously with succinic acid when nitric acid acts upon sebacic acid.

OXYSYLVIC ACID. A resinous acid which has hitherto been only very imperfectly investigated.

OXYWATER. A name sometimes applied to binoxide of hydrogen. [HYDROGEN, *Binoxide of.*]

OYER AND TERMINER. These words in ancient law French denote a commission forming a court of criminal judicature, the distinguishing character of which is described by them. The substance of the commission, or *writ*, as it was anciently called, is an authority given by the crown to certain persons judicially to *hear and determine* (oyer et terminer) certain specified offences. The commissions of oyer and terminer are the most comprehensive of the several commissions which constitute the authority of the judges of assize on the circuits. On these occasions they are usually directed to the lord chancellor, several high officers of state, two judges of the courts of Westminster, the queen's counsel, the serjeants-at-law, and the associates; but (excepting on the northern circuit, where all the commissioners but one are of the *quorum*) the judges, queen's counsel, and serjeants are always of the *quorum*, so that the other commissioners cannot act without the presence of one of them. Justices of oyer and terminer have jurisdiction to inquire into the truth of all treasons, felonies, and misdemeanours committed within the several counties and places to which the commission extends, and also to *hear and determine* the same on certain days to be appointed by themselves. The issue of such a commission suspends all others, and hence magistrates cannot proceed under a commission of the peace at the same time. Besides these ordinary courts of oyer and terminer at the assizes, special commissions of oyer and terminer are sometimes issued where offences of a dangerous tendency have been committed in particular districts, and the public peace and security require immediate inquiry and punishment. So also special commissions have been sometimes issued where from particular circumstances the incompetency of the ordinary tribunals would occasion a failure of justice. A remarkable instance of this kind occurred when Mr. Dunning, afterwards Lord Ashburton, was recorder of Bristol and sole criminal judge under the charters of the city. A forgery of Mr. Dunning's name to a bill of exchange having been committed in Bristol, he refused to try a case in which he was a party interested, and it was therefore necessary to issue a special commission for the purpose of hearing and determining this single offence.

The Central Criminal Court is a court of oyer and terminer (and jail delivery) for the jurisdiction assigned to it by statute, comprising the metropolis and portions of the adjoining counties. The jurisdiction of the magistrates in quarter sessions is expressly preserved by the statute, for otherwise they could not hold courts at all.

OYSTER TRADE. The management of the oyster fishery presents many peculiar features. The best kind of oysters in this country are the small variety called *Natives;* they are found near the mouths of the rivers Colne, Blackwater, and Crouch, in Essex; the Swale and the Medway, in Kent; the Ouse, in Sussex; in Southampton Water; and at other places in all the three kingdoms. These artificial beds are usually supplied with the produce of the coast of Normandy, whence the spat or spawn is gathered. The spawn, when first cast, somewhat resembles in appearance a drop of fat; it is composed of an immense number of minute oysters, each of which becomes about a quarter of an inch long in three days, as large as a shilling in three months, as a half crown in six months, and as a crown in twelve months. They are stated to attain their highest degree of perfection when three years old. The oyster is found in the seas of most countries, but never at any great depth, and seldom far from the mouth of a river. The fishing for oysters is permitted from the 1st of August to the end of April.

The fishing, or, to use the more correct term, the dredging, is carried on to a large extent by small sailing- and row-boats—they usually dredge in company, as the oysters lie within comparatively small spaces. The dredge is a net on a wooden or iron frame, and is weighted according to the nature of the bed, varying from 12 to 18 pounds. It is thrown by one man, while another rows. The beds or banks are found in the British Channel; off the Isles of Wight and Jersey; on the coast of Wales; off the French coast. In Scotland they are found in the Frith of Forth; in Ireland, in Carlingford Bay, the oysters from which have a high character for excellence. France has also numerous artificial beds, but the fishermen also dredge in the Channel, where frequent disputes arise between them and the English fishermen respecting boundaries. The most esteemed natural beds in France are those off the coast of Brittany, at Dieppe, and Cancalle, near St. Malo.

So far as regards the London supply, the oysters are brought principally from the Essex coast and rivers; but the Milton, Feversham, and Burnham oysters are most highly esteemed. None are sent from the north of England; but broods are sent from thence to be fattened in the artificial beds. The sale at Billingsgate is enormous. At Southampton there is a wide margin of muddy shore at low water, on parts of which oyster-beds are formed. Oysters are brought from the Jersey fishery, laid down on those beds to fatten, turned and attended to every day, taken up when wanted, opened, placed in tin cans, and sent up to London by railway. These oysters are used for pickles and sauces, and not eaten in the ordinary way.

The oyster trade in England has been of considerable importance for centuries, and now ranks next to the herring-fishery. The dredging, the laying down spawn in the artificial beds, and attending to and gathering the oysters, and the packing for market, give employment to a large number of persons; while the rapid conveyance afforded by railways enable the inland towns to obtain oysters perfectly fresh and in excellent condition; and at Christmas the quantity transmitted in barrels as presents demands additional accommodation, not only from railways, but from every other means of inland transmission.

OZONE (from the Greek ὄζω, to smell) is the name given by Professor Schönbein of Basle to an odour evolved during the progress of certain electro-chemical decompositions. It is also produced by common electric sparks, and by the working of an ordinary electrical-machine in the air. This odour attracted no particular notice until M. Schönbein called the attention of the British Association to it in 1840, since which time it has undergone much examination, and various theories have been propounded as to its nature and composition.

Ozone is evolved at the anode, or positive pole of a galvanic battery, at the same time with oxygen, during the electrolisation of any of the following bodies: namely, water, dilute sulphuric acid, solutions of phosphoric and nitric acids, potash, and many oxysalts. Of these, dilute sulphuric acid mixed with chromic acid yields it in the greatest quantity. It may also be obtained from atmospheric air, by passing the electrodes through a closely-fitting cork into a jar filled with air, and frequently making and breaking contact. Under the influence of heat ozone disappears, and it cannot be obtained from heated solutions, or solutions of hydracids, chlorides, bromides, or iodides, the presence of which, even in small quantity, prevents its evolution from solutions otherwise yielding it abundantly. It may be developed by electrolising a solution of chloride of sodium with platinum electrodes, by placing the gas collected at the anode over ammonia and water to absorb the chlorine. Ozone can be preserved for a length of time with the oxygen collected with it in well-closed bottles. It possesses the property of bleaching litmus-paper and paper coloured with indigo or a solution of that substance. It is readily absorbed by mercury and the oxidisable metals, forming oxides with them; and when the solutions employed are heated, its affinity for metals is so greatly increased that it oxidises platinum and gold. Water absorbs it. The inspiration of ozone is very injurious, the effects being similar to those resulting from chlorine and bromine. A mouse is killed with it in five minutes; and M. Schönbein states that he was seriously affected by breathing an atmosphere charged with it.

The electrodes employed in these experiments have a great influence in respect to the evolution of ozone. With water or acid solutions they must be of platinum or gold; for when the more oxidisable metals are used it enters immediately into combination with them. It can be obtained from air when the positive electrode is copper, iron, silver, or platinum, and zinc negative, but not when these arrangements are reversed, or both electrodes are of zinc. On electrolising a solution of sulphuric acid the following results are obtained:—With platinum electrodes the odour is very powerful; but it is not produced when copper, zinc, or iron electrodes are employed. With boxwood charcoal, the gas given off from the positive pole has no smell; but when absorbed by lime-water it turns it milky, proving the gas to be carbonic acid. With gas charcoal, sulphuretted hydrogen is evolved at the negative pole and carbonic acid at the positive, but no odour of ozone is produced. With a solution of chloride of sodium, the odour is not perceptible until the gas obtained from platinum electrodes at the positive pole is placed over ammonia and water to absorb the chlorine. The residual gas emits the peculiar odour.

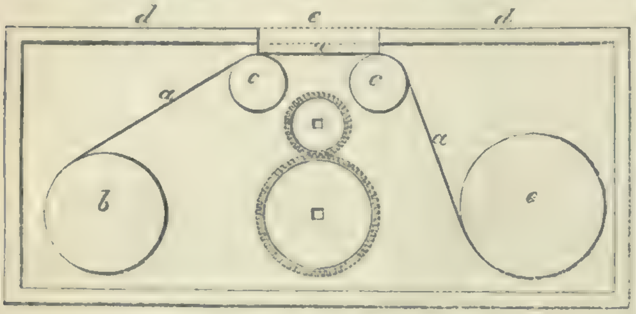
There exists much variance in the experimental results with this new substance, and not less in the opinions concerning its nature. Professor Schönbein and Dr. Andrews regard it as oxygen in an allotropic condition, whilst Dr. Williamson and M. Baumert consider it to be a teroxide of hydrogen. The latter chemist has even succeeded in analysing ozone, and thus quantitatively demonstrating its composition; nevertheless, Dr. Andrews calls in question the accuracy of these experiments, and adduces others in proof of his view of the composition of this substance.

Tests for Ozone.—Notwithstanding the remarkable characters of this body, no reliable test of its presence in minute quantity (in the air, for instance) is known. Paper imbued with starch and iodide of potassium is rendered blue by ozone, but the same effect is produced by acid gases; and this test, as used for the detection of ozone in the air, is utterly worthless. Paper soaked in solution of sulphate of manganese, which is turned brown, or impregnated with black sulphide of lead, which is bleached by ozone, are more reliable tests; but even these are open to so many sources of fallacy as to render their indications of little value. [HYDROGEN, *Teroxide of.*]

OZONOMETER, an instrument for measuring the quantity of ozone contained in the atmosphere. The only means of ascertaining the presence and quantity of this agent in the atmosphere, is founded upon the known action of ozone in decomposing iodide of potassium. If this salt be exposed to the action of an atmosphere containing ozone, the latter unites with the potassium, forming oxide of potassium or potash, whilst the iodine is set free. In order to render this test obvious, the iodide of potassium is mixed with starch, and the iodine, when it is set free, unites with the starch, the existence of which is immediately ascertained by its blue colour: it is right, however, to add that the sufficiency of the test is not unquestioned. [OZONE.]

Schönbein, who originally described ozone, proposed this test and made use of it, by saturating paper with a solution of iodide of potassium and starch. As the result of using this paper was to indicate the quantity of ozone in the atmosphere by the intensity of the blue colour produced on the test paper, it was necessary for comparison to use the same test paper; hence Schonbein undertook to supply this paper from his own laboratory, and pieces of paper for every day in the year are sold in boxes under the name "Schönbein's ozone test paper." In this country Mr. Moffatt has distinguished himself by his researches in atmospheric ozone, and he also prepares a paper for supplying those who wish to measure the presence of ozone in the atmosphere. With these papers a scale of colour is supplied, each shade of colour showing the action of the ozone on the iodide and starch being marked from 0 to 10 In using this paper a slip is taken and exposed in some place to which the air has access, and there it is left for twenty-four hours. At the end of this time the paper is compared with the scale, and according to the intensity of its colour it is marked from 0 to 10.

Although this method indicates the existence of ozone at some time within the twenty-four hours, it fails to indicate the exact time at which the ozone was present, and prevents also any accurate comparison with other meteorological phenomena, as heat, wind, moisture, &c. In order to render the registration of ozone more accurate, Dr. Lankester has invented an ozonometer, by which a strip of ozone paper 24 inches in length is exposed successively for an hour to the action of the atmosphere. In this way the ozone of each hour can be indicated, and the sum of its effect on the paper more easily ascertained. Dr. Lankester's instrument consists of a box (*fig.* 1): the iodised paper *a a a* is first carried round the wheel *b*, and passed on to the two cylinders *c c*. When the lid of the box, which is made of brass, *d d*, is down, it covers the whole box except a small space, *e a*, one inch in length and half an inch in width, which is cut in the lid, and through this the paper *a* is exposed to the action of the air. The strip, after this exposure, is carried from the cylinders *c c* to the wheel *e*, on which it is wound up. The machinery which moves the wheels is precisely similar to that of a clock, and the instrument is wound up in the same way. The following table will illustrate the method of registering the intensity of the ozone by this instrument:—



Section of Lankester's Ozonometer.

The results of ozonometric experiments show that ozone is seldom present in the atmosphere of great cities. It is generally present in air coming from the ocean, and in rural and mountainous districts, where the air is free from the contamination of animal and vegetable matter. On the sea-coast of Great Britain it appears to be more abundantly present than away from the sea. It has also been observed in larger quantities on the southern and eastern coasts of England when the wind blows from the south, or west, or south-west. As the wind veers from west to north, or from south to east, it diminishes.

P

P is the tenuis or thin letter of the labial series. For the various symbols employed to denote this letter see ALPHABET.

This letter is interchangeable with those which belong to the same organ, that is the lips, and with some others. Thus,

1. P is convertible with a *b*. The Latin, like the Welsh, was fond of the thin letters, in consequence of which there are very few words in that language which begin with *b*, while those commencing with *p* form a numerous class. It will often be found that the *p* in Latin words becomes a *b* in the related languages. Thus *apicula*, the diminutive of *apis*, a bee, is in French *abeille*; *septem* is in German *sieben*. The German language often confounds *b* and *p*, more particularly when the former is final. Perhaps, too, even in Latin, the written *b* was pronounced as a *p* in the prepositions *ab*, *sub*, *ob*, which correspond to the Greek απο, ὑπο, επι.

2. *P* with *m*, somewhat rare. Thus the Greek preposition μετα is in the Æolic dialect πεδα. Again, the Greek μολυβδος is essentially the same word with the Latin *plumbus*. Allied to this change is the insertion of a *p* between either *m* and *s* or *m* and *t*, as in the Latin *sumpsi*, *sumptus*, for *sumsi*, *sumtus*, and *temptare* for *tentare*.

3. *P* with *v*. This change is more particularly to be observed in the derivation of French from Latin. Thus, from *capillus*, hair, *episcopus*, a bishop, *decipere*, deceive, &c., *aperire*, open, *opera*, work, *lepus*, hare, *pauper*, poor, *piper*, pepper, *Aprilis*, April, the French have deduced their *cheveu*, *evêque*, *decevoir*, &c., *ouvrir*, *œuvre*, *lièvre*, *pauvre*, *poivre*, *Avril*.

4. *P* with *f*. Two or three examples are given under F. To these may be added *pro*, *for*; *pater*, *father*; *piscis*, *fish*; *pauci*, *few*; *lupus*, *wolf*. So the Greek πορφυρα, φαινολη, Φοινιξ, have the aspirate, while the Latin, as usual, prefers the tenuis in *purpura*, *pænula*, *Poenus*.

5. *P* with *pf*. The latter form is often preferred by the German, where our own tongue has the single letter. Thus the English words *pound*, *peach*, *pepper*, *pea*-cock, *penny*, *apple*, are written by the Germans *pfund*, *pfirsche*, *pfeffer*, *pfau*, *pfennig*, *apfel*.

6. *P* with *c*, *k*, or *q*. See C.

7. *P* with *t*, as ταως, in Latin *pavo*. The Greek interrogative words beginning with a π, as που, πῃ, ποτερος, &c., are related on the one hand to the Ionic forms κου, κῃ, κοτερος, and on the other to the demonstratives that commonly take a τ at the beginning. And in fact the latter are often used as relatives.

8. *P* with *pt*. The latter is common in Greek, as in τυπτω, οπτομαι, &c., which form their other tenses for the most part without a τ. So too at the beginning of words. Thus πτολις and πτολεμος coexist with πολις and πολεμος; and it seems probable that it was an unsuccessful attempt to pronounce the initial *pt* which led to the formation of the Latin words *populus*, a state, and *populari*, to devastate with war.

9. *Ps* with *sp*. This change it will be more convenient to consider under the letter S.

10. *Pi* before a vowel with *ch*. Thus *sapiam*, in Latin, becomes *sache* in French. The word *roche*, too, was probably formed from a barbarous Latin word *rupia*; and *Rutupium*, in the county of Kent, appears upon this principle to have changed its named to *Richborough*.

PACE (*Passus*), a measure of the Roman system, being in fact their unit of itinerary measure, to which the *mille passus*, or MILE, was referred. The word *passus* is connected with the root of *pandere*, to extend, and Paucton curiously enough derives it *à passis manibus*, from the length between the extended hands, instead of *à passis pedibus*. There is however reason to believe that the mille passus came into use from the practice of measuring distances in new countries from the number of paces marched by the soldiery, of which a rough reckoning was kept, but whether by actually counting the paces, or by the time of marching compared with the previously known number of paces in a given time, is not known. It is well known that with disciplined soldiers either method would give very good practical results. Vitruvius describes a machine to be fastened to the wheel of a chariot (an invention revived in our own day), by which its number of revolutions was registered; but this was probably a late invention.

The pace was not, as persons in general suppose, the step or the distance from heel to heel when the feet are at their utmost ordinary extension; this, which the French metrologists call *pas simple*, was the *gradus* or *gressus*. The passus, or *pas double* of the same writers, was two gradus, or the distance from the point which the heel leaves to that on which it is set down. Assuming the Roman foot at 11·62 English inches, the pace, which was five feet, must have been 58·1 inches or 4·84 English feet.

Here we might have stopped, if it had not been necessary to explain something relative to what it pleased the writers of the middle ages to call the *geometrical* pace, composed of five geometrical feet. What they meant by this measure is not easily understood, except by the supposition (which some of their writings confirm) that they imagined a fixed and universal measure of length to exist in nature, and to have been actually obtained. At the beginning of the 16th century the Roman mile, at least the mile of 5000 feet or 1000 paces, was generally used by writers [MILE], and itinerary measures were more often written about than verified. The stadium, or eighth part of this mile, had also been introduced (into books) from the Greek system, and it was the common opinion, derived from Ptolemy, that the degree of latitude was exactly 500 stadia, or 62½ miles. This made the pace, or the 125th part of the stadium, stand forward as a proper universal measure, being the 62500th part of that which all believed the degree of latitude to be. But though this may be a probable origin of the geometrical pace, it is certain that writers did not adhere uniformly to it, so that the later metrologists have formed different notions of its length. We shall give the accounts of several modern writers.

Dr. Bernard makes the geometrical pace (which he also calls the land-surveyor's pace) to be five English feet. Greaves supposes that a pace of upwards of 69 inches was once in use in England. Ozanam makes the geometrical pace to be the same as the Roman pace. Eysenschmidt does not mention the measure at all. Paucton (who has a theory about the derivation of measures from parts of the human body) makes it only 4½ Roman feet. Romé de L'Isle, who contends that Paucton has several times confounded the Greek Olympic foot with the Roman foot, makes it 4½ Olympic feet, that is, 4½ English feet very nearly. An old writer, Samson d'Abbeville, cited by Paucton, lays down the geometrical pace at 5 French feet, and nevertheless makes the Roman mile to contain a thousand such paces. The conclusion is, that the geometrical pace was an invention of the old writers, a needless addition to the confusion in which their accounts of ancient measures were already enveloped.

There is a pace mentioned in ecclesiastical writers called *passus ecclesiasticus*, or *dexter* (see Ducange, at the word Dextri), which Dr. Bernard, without stating any authority, makes of the same length as the English yard.

PACKFONG. [GERMAN SILVER.]

PACKING-PRESS. The hydraulic press invented by Mr. Bramah, besides being used to draw piles, trees, &c., from the ground, or to prove the strength of materials, is frequently employed to pack or compress bales of linen, cotton, and the like goods into small dimensions for the convenience of transport. A description of this machine has been given under HYDRAULIC PRESS; and it is intended here merely to notice the method employed by Mr. Barlow to determine the thickness which the cylinder should have in order that its strength may be in equilibrio with the strain to which it is subject from the pressure of the fluid within it.

Within any section of the cylinder made by a plane perpendicular to the axis, the tendency of the contiguous particles of metal to separate from one another in a direction perpendicular to a diameter passing through them, in consequence of the expansion produced by the pressure of the fluid, becomes continually less from the interior to the exterior circumference of the section, and is inversely proportional to the distances of the particles from the axis of the cylinder; and the cohesive power of the particles is, by the laws of elasticity, proportional to their separation, while the strain produced by the pressure of the fluid varies, at any part of the section, with the distance of that part from the axis. It follows that the resistance opposed at such part of a section to the momentum of the pressure is inversely proportional to the square of the distance from the axis.

Therefore r representing the radius of the interior surface of the cylinder, t the whole thickness, and x any variable distance from the interior surface towards the exterior, all in inches; then $\int \frac{r^2\, dx}{(r+x)^2}$, if multiplied by 2π, and also by the force of cohesion on a square inch of the metal, will express the resistance produced by an annulus which is one inch deep in a direction parallel to the axis. That integral, for the whole thickness t, is $\frac{rt}{r+t}$; therefore f (in pounds) denoting the force of cohesion, $\frac{2\pi rtf}{r+t}$ expresses the whole resistance.

If f' (in pounds) represent the force on a square inch of the interior surface, by which the pressure of the fluid tends to strain the cylinder, $2\pi rf'$ will denote the whole strain on the same annulus; therefore, equating the strength and strain, there is obtained

$$t=\frac{rf'}{f-f'}$$

This value of t expresses the required thickness.

PÆDO-BAPTISTS (those who baptise children, from *παῖς* and *βαπτίζω*), a term used by modern theological writers, not as the designation of any particular body of Christians, but for the sake of distinguishing all those, of whatever sect, who practise infant baptism, from the body who are called Baptists. [Baptists.]

PAGODA. [Chinese Architecture.]

PAINTER'S COLIC, called also Devonshire colic, and colic of Poitou, from its former frequency in those parts, is a peculiar and well-known variety of colic, to which lead-miners, painters, and others who use that metal are subject. The symptoms are, severe pain in the belly, with obstinate constipation and occasional vomiting, which is generally followed by partial palsy, and in violent cases by apoplexy. The palsy mostly affects the upper extremities, so that the arms hang powerless by the sides, the extensor muscles being the most impaired. Emaciation and paleness of the muscles affected are of very frequent occurrence.

"A first attack, taken under timely management, is for the most part easily made to terminate favourably. In such circumstances it rarely endures beyond eight days. But it is exceedingly apt to recur, especially if the patient return to a trade which exposes him again to the poison of lead. Sometimes the primary stage of colic is wanting, so that the wasting of the muscles and loss of power are the first symptoms." (Christison.) A peculiar livid line along the gums close to the teeth, is an invariable concomitant characteristic of lead-poisoning from the habitual exposure to it.

The principles to be observed in the treatment are, to remove the pain and constipation, and to obviate or lessen the remote effects. In first attacks it is not very difficult to effect the former object, but with every succeeding attack these symptoms are found more obstinate. Inflammation is rarely a primary symptom, but may ensue, as in other kinds of colic. Want of power in some portion of the bowel, by which it becomes distended, and excessive contraction of another portion, are the usual conditions.

By saline purgatives, such as sulphate of magnesia, sulphate of alumina and potass, or phosphate of soda in solution, followed shortly by a large dose of opium, the constipation may be removed in the milder cases. To counteract the occurrence of inflammation, calomel and opium are preferable means to bleeding, in a disease where debility is one of the usual consequences. The constipation has been known to last for a month. In such a case it was customary to give the patient three or four pounds of crude mercury, in the hope that by its mechanical properties it would force a passage. Nothing is more reprehensible, as it irritates the contracted part of the bowel, and distends yet further the enfeebled and dilated part. Most cases of constipation will yield to pills of aloes and sulphuric acid, in the proportion of one drop of strong sulphuric acid to four grains of powdered aloes. Two of these pills every four or two hours will speedily remove this state.

The paralysed arms must be supported by splints. It is however of little use to cure a first attack, if the sufferer be immediately the subject of a second, which he certainly will be without the greatest care. Should he be unable to change his employment, he must be very strict in the observance of the following rules: he should never eat without first thoroughly washing the hands and face; and never take his meals in the workshop. "Yet it is the common practice of the smelters of lead," says Dr. Percival, "and others also who live in the neighbourhood of smelting-mills, to broil mutton, beef, and pork steaks on the hot pigs of lead, by which the flesh acquires a peculiar agreeable flavour." When leaving work, a different suit of clothes should be put on, and when baths are attached to the manufactory, a complete immersion in these, after work, is advisable. The miners of Alston Moor derive great benefit from the saline mineral waters of Cartnell Holywell, to which they annually resort. Here, besides the chemical constitution of the waters being appropriate, an action on the bowels is caused, and it is observed that an open state of the bowels is always a great protection. On this account many masters keep a supply of castor oil on the premises, to which the workmen have free access. Fat and oily food is likewise a great safeguard. Sobriety is still more effective as a safeguard, for it is observed that among miners, potters, and all persons working among lead, drunkards suffer soonest and most severely. In all cases where the dust of the lead can be kept down by watering, this should be done, as it proves a very valuable means of exemption. Wherever it is practicable, other more innocent articles should be substituted for lead, in the various manufactures where it is now used. [Lead.]

(Christison *On Poisons;* and Thackrah *On the Effects of Arts, Trades, and Professions.*)

PAINTING is the art of representing objects by means of colour on a plane surface. In the present article it is intended, not to enter upon the question of the purpose or the limits of the art, nor to discuss its principles or practice, but merely to give a broad sketch of its history, leaving the details to be filled in by a reference to the names, in the Biographical Division of this work, of the principal painters mentioned in the course of the article.

As far as our knowledge extends the history of painting commences with Egypt, where it may be traced back to a very remote antiquity. Of the two arts, sculpture was probably the elder; and painting may at first have been chiefly exercised in connection with it: statues and rilievi being first coloured with more or less taste and skill, and then outlines and figures in sunk relief (intaglio rilevato) being carved on pillars and walls, and the enclosed space coloured to imitate the natural appearance of the objects. But during the 18th dynasty, or 1400 B.C., and downwards, the most flourishing period of the arts in Egypt, painting proper, according to the definition given at the commencement of this article, was commonly practised. Egyptian painting has been conveniently divided into three classes: mural painting; painting on mummy cases; and painting on papyrus; to which might be added the portraits on wooden panels, of which several have been found in mummy cases, and which also appear, from passages in Greek authors, to have been presented as votive offerings in the temples. The earlier painting was strictly hierarchic and symbolical; later it became somewhat freer, but always it was closely bound by conventional rules, and as much a mechanical as an intellectual art. The human form was depicted according to a definite canon, of which there is an example in a tablet in the British Museum at least 3000 years old. In all Egyptian paintings the human figure is drawn with less truth and freedom than figures of animals; but in neither is there any attempt at foreshortening. The subjects on the walls of tombs, which are most like pictures as the term is commonly understood, comprise chiefly religious or funeral ceremonies, rural occupations, fowling, banquets, and household employments. In these, little of what is called composition or grouping appears to have been attempted; the colours are bright, and unbroken by modification of tint, or light and shadow; and the artists were ignorant of perspective, the figures being placed one above another, and such objects as a rectangular fish-pond being drawn as on a ground plan, almost precisely as in the rude pictures of the ancient Mexicans. The colours used are the primitives, red, blue, and yellow; with green, black, brown, and gray. They have been shown by analysis to consist of metallic oxides, as well as of vegetable pigments. The vehicle employed with the colours was usually glue, but occasionally, though probably only at a comparatively late date, wax dissolved in naphtha was also used. The picture was sometimes covered with a varnish of glue, in order to preserve the colours from the dust or from atmospheric action, and occasionally a varnish of resin appears to have been employed for the same purpose.

From the state in which Belzoni found the great tomb of the kings of Thebes, and from an examination of various mural paintings, the method of working adopted by Egyptian painters has been ascertained with tolerable precision. After the wall was made quite smooth it was covered with an intonaco of fine lime and gypsum, which was suffered to dry, and then polished. Upon this the outline of the figures was carefully drawn, of sufficient strength to show through a thin coat of limewash which was spread over it; and upon this the colours, mixed with glue prepared from thick hides, were painted. For the paintings on mummy cases the wood was usually covered with cloth saturated with glue; on this cloth was spread a ground of gesso, and upon this the pigments, rendered opaque by an admixture of chalk, or simply mixed with glue, were laid. The portraits on tablets of cedar, sometimes found in mummy cases, are also covered with a coating of gesso, and in these portraits some approach is made to the modulation of surface by means of light and shade. The British Museum contains a great many examples of Egyptian paintings and painted hieroglyphics. Among the most interesting is a series of twelve fragments of frescoes (Nos. 169–180), painted as described above, which were brought from a tomb at Thebes, and which contain representations of the royal granaries; the taking of fowls, and of fish; foreigners bringing tribute; royal banquets and entertainments, with musicians, dancers, &c. In the First Egyptian Room at the British Museum (Case 39), are many of the implements used by Egyptian painters, including rectangular pallets, with grooves for the brushes and reed pens, and wells in which the colours were kept mixed for use; also colour boxes; mullers and slabs for grinding the colours; fragments of colours, and a brush made of the fibres of palm-leaves. (The great work of Rosellini, 'Monumenti dell' Egitto' (Tavoli Mon. Civili), contains numerous examples of Egyptian paintings: see also Wilkinson's 'Ancient Egyptians,' and 'Egyptian Antiquities,' vol. ii.)

Of Assyrian pictures, no instance has, we believe, been found. That they had "images of men portrayed on the walls" in gorgeous raiments and with bright colours we know; but these were no doubt the sculptured slabs of which Botta and Layard exhumed so many examples, and which from the traces of colour found on them, as well as from secondary evidence, we know to have been originally brilliantly painted. But that the Assyrians painted pictures even of the kind which the Egyptians painted we have no proof.

Painting in Greece.—The origin of painting, like that of most of the arts, was involved by the ancient Greeks in their legendary history. There can be little doubt that Painting like Sculpture was derived by the Greeks from Egypt. In their traditions respecting the inventors of drawing and colouring they may however have preserved some memorials of those who assisted in raising the art from its primitive rudeness and narrowness of scope. Homer, though he mentions garments elaborately embroidered or woven with figures, speaks of nothing nearer akin to painting than the colouring of the ships or the staining of ivory by a Carian woman. The origin of the art in its simplest form of the outline of a shadow, is ascribed to Corinth or Sicyon; but the story of its supposed inventor, as recorded by Pliny, is evidently deserving of little attention. Cleanthes of Corinth is said to have made the first outline; Ardices, of the same city, and Telephanes of Sicyon, to have introduced some lines within the figure; and Cleophantus to have coloured it with a single colour, and thus produced *monochromata*. Corinth was the great centre of the ceramic art, and these frequent references to Corinthian painters point with sufficient distinctness to the early connection between the potter's art and painting. The legend of Cleophantus, or Eucheir and Eugrammus, having accompanied Demaratus from Corinth to Italy (Olymp. 30, B.C. 657), probably points to the early connection of Greek and Italian art, or to the taste for the former which existed in Etruria and the neighbouring countries, as is sufficiently attested by the innumerable vases with Greek stories and Greek inscriptions now found in Italy. The grotesqueness and clumsiness of the figures on the earlier vases, and their progressive improvement, show how little ground there is for the notion that the proportions of the human figure in early Greek art were fixed by some type derived from Egypt or elsewhere, instead of gradually developing themselves as the culture of the race advanced

The very curious paintings on the walls of the Etruscan tombs should here be mentioned; and Pliny speaks of ancient works existing in his time in a temple at Ardea, as well as at Cære and Lanuvium.

Between the 50th and 80th Olympiad (from 580 to 460 B.C.) painting advanced considerably in Greece.

Historical pictures of very early events are recorded, one indeed by Bularchus, in the reign of Candaules, who died Ol. 16. 1, B.C. 716. Cimon of Cleonæ invented *catagrapha*, that is, figures seen obliquely from above or below, and thus applied the rules of perspective. The peculiarities of drawing of this early period are best learned from the study of the ancient vases; the forms and protuberance of the muscles are exaggerated, and the positions strained and whimsical.

Polygnotus of Thasos, who probably settled at Athens about Ol. 79. 2 (B.C. 463), was the first painter of great excellence, and the founder of what may be called the Athenian school. Aristotle ('Poet.,' vi. calls him *ἀγαθὸς ἠθογράφος*, "successful in his expression of character;" and speaks of him as painting men better than they are. The characteristic of his style was elevation and largeness of design, with purity of form and force of expression. Pliny speaks of him as having abandoned the old stiffness, and having given movement to the features. His transparent drapery is also mentioned. Pausanias (x., 25-31) describes his pictures in the Lesche at Delphi—the Capture of Troy, the Departure of the Greeks, and Descent of Ulysses to the Shades. In the Pœcile at Athens his works stood by the side of the Battle of Marathon by Panænus, the nephew or brother of Phidias, and of the Combat between the Athenians and the Amazons by Micon. This latter artist, together with Onatas of Ægina and Dionysius of Colophon, were the most celebrated contemporaries of Polygnotus.

The principles of light and shade were investigated by Apollodorus of Athens about the 94 Ol. (B.C. 404). To the school of Athens succeeded what may be termed that of Ionia, in which illusion seems to have been more aimed at. This we may infer from the well-known story of the grapes of Zeuxis and the linen cloth of Parrhasius. Zeuxis, with whom begins the second epoch of the more advanced art, was of Heraclea, and flourished about Ol. 94. (B.C. 404). His excellence seems to have been equally conspicuous in female beauty (as the Helen of Crotona), and the sublimity of Zeus and his attendant gods; whilst in technical skill he surpassed all his predecessors.

Parrhasius was of Ephesus, and he is no less celebrated for the roundness and relief of his figures than for their exquisite form and expression. His contemporary Timanthes overcame him in one of those contests between painters which were not unfrequent in Greece, and which are said to have been first instituted at Delphi in the time of Panænus. Among the ancient paintings from Pompeii is one of the same subject (the sacrifice of Iphigenia) as that of Timanthes, mentioned in Pliny, and in which the grief of the father is represented in the same way by the concealment of the face.

Another school arose at Sicyon, in which the most celebrated names were—Euphranor of Corinth (Ol. 104-110, B.C. 364-340), Pausias of Sicyon (Ol. 103, B.C. 368), Aristeides of Thebes (Ol. 102-112, B.C. 372-332), and Pamphilus of Amphipolis (Ol. 97-107, B.C. 392-352). The first of these, a sculptor as well as a painter, was laborious and consistently excellent in all that he undertook. Aristeides was remarkable for his expression of passion; Pausias practised encaustic painting with great success, having acquired the art from Pamphilus. Pausias was noted for his children and lighter subjects, and first decorated roofs and arches with figures. Pamphilus succeeded in establishing a knowledge of the rudiments of drawing as part of a liberal education. He was moreover the teacher of Apelles, who united the softness and colouring of Ionia with the science of the Sicyonian school. His excellence in female beauty was attested by the Aphrodite Anadyomene at Cos; his power in sublime subjects and his technical skill, by the Alexander wielding the Thunder at Ephesus. The liberality of Apelles first brought into notice a rival of his fame, Protogenes of Rhodes, or rather of Caunus in Caria. This artist excelled in a laborious study of nature, and Apelles declared that his own superiority over Protogenes consisted in his knowing when to leave off. They both executed numerous portraits, and Apelles was honoured with the exclusive privilege of painting Alexander the Great. Nicomachus probably preceded Apelles; he seems to have rivalled Luca Giordano in quickness of execution. Nicias of Athens, Theon of Samos, and Melanthius were contemporaries of Alexander. The first of the three was excellent in light and shade, and painted battles and historical subjects on a large scale.

From the death of Alexander, and as a consequence partly of the political disturbances which followed, the decline of painting was continuous. Painters indeed met with ample encouragement, but they worked for private rather than public enjoyment, and their attention was directed mainly to a lower class of art,—to that which could be produced rapidly for the glorification of kings and rulers or the gratification of the affluent. Instead of representations of the gods, and of the great events of epic verse or Hellenic history, works of the class we now call *genre*, low and domestic subjects (rhypography), and even pornography (obscene pictures), were eagerly sought. These last became more general as the art fell lower, and painters sought popularity by novelty of style and familiarity of subject, or gain by making their art the creature of luxury and sensuality; but even Parrhasius was noted for pictures of a libidinous character. Vase-painting gradually died out in this period; but, on the other hand, mosaic was introduced, and acquired great popularity, and Greek musivarii were in much request for the preparation of mosaics for Rome. Landscape-painting was likewise introduced late, and never flourished among the Greeks, though the art was cultivated by Greek painters for the gratification of their Roman employers.

Some time before the spoliation of Greece, Greek painters had migrated to Rome and found employment there. But as the plunder of the Grecian cities by the Roman generals went on, the passion for works of art among the Romans seemed to increase; and as the love of art, or the power of rewarding its professors, declined in Greece, Grecian artists betook themselves in constantly increasing numbers to the Roman capital, so that about the end of the republic Rome was spoken of as full of them. Many migrated also to Egypt and Asia, and elsewhere, until such Grecian painters as were left were to be sought anywhere rather than in their native country.

Instead of tracing further the decay of the art, it may be well to speak briefly of the kinds of painting practised and the materials employed whilst Greek painting was in its maturity. The earliest occupation of the painter in Greece, as in Egypt, seems to have been in colouring sculpture; and from the gaudy daubing of the primitive wooden figures of the gods, down to the refined tinting of the most exquisite statues of the greatest of the Greek sculptors, this was always regarded as a branch of the painter's art. Praxiteles himself, according to the well-known story, when asked which of all his statues he preferred, replied, "That in which Nicias had a hand"—Nicias being one of the most eminent painters of his time. What this *circumlitio*, as Pliny terms the statue-painting of Nicias, really was, will be considered under another head. [POLYCHROMY.] Another of the branches of the art for which the painters were always famous—that, namely, of vase-painting—will also be noticed more conveniently elsewhere.

The pictures ordinarily painted by the Greeks up to an advanced stage of the art, appear to have been almost exclusively easel pictures executed in tempera. They were painted chiefly on wooden panels, which had probably been prepared with a gesso ground; but paintings were also executed on stone, plaster, parchment, and, though not till a late period, on canvas. Glue or size, white of eggs, and gum were the vehicles commonly used in mixing and applying the colours. Wax was also used, boiled with mastich or mixed with a mineral alkali, so as to be employed as a water-colour medium. The application of wax by means of fire, or encaustic painting, was of later introduction; for though practised by Pausias, who is said to have learned the method from Pamphilus, it was not generally adopted till about the time of Alexander. [ENCAUSTIC PAINTING.] Fresco-painting was also of late introduction, but in the later stages of the art was, either alone or in conjunction with encaustic, much employed in paintings on walls and ceilings, and generally in works of a decorative character. Vitruvius says that the Greeks attained such skill in the preparation of fresco walls, that, in his time, people were accustomed to cut slabs from them, which could be packed up and carried to any distance. The finer fresco-paintings, according to Vitruvius and Pliny, were, when finished, covered with an encaustic varnish, which heightened and preserved the colours. Oil as a vehicle appears to have been unknown.

The four colours which were the basis of the colouring of the Greeks down to the time of Apelles were—1, white, Melian earth, or, more rarely, cerussa, white lead; 2, red, rubrica from Cappadocia, called sinopis; 3, yellow, sil, *ὤχρα*, from the Attic silver-mines; 4, blacks (probably including blues), atramenta, *μέλαν*, from burnt plants or ivory. These were the "*colores austeri*," to which were afterwards added the brighter and more expensive colours, "floridi," which were usually furnished to the painter by his employer; but the palette appears always to have been restricted to a comparatively few well-chosen and carefully-prepared colours. This restriction to a few colours was one of the things which satisfied Sir Joshua Reynolds—an indisputable authority in a question of colour—of the superiority of the Greeks as colourists. Another, was their use of atramentum. "What disposes me," he wrote (Note xxxvii. to Du Fresnoy), "to think higher of their colouring than any remains of ancient painting will warrant, is the account which Pliny gives of the mode of operation used by Apelles; that over his finished picture he spread a transparent liquid like ink, of which the effect was to give brilliancy, and at the same time to lower the too great glare of the colour: 'Quod absoluta opera atramento illinebat ita tenui, ut id ipsum repercussu claritates colorum excitaret;—et cum ratione magnâ, ne colorum claritas oculorum aciem offenderet.' This passage," he adds, "though it may possibly perplex the critics, is a true and an artist-like description of the effect of glazing or scumbling, such as was practised by Titian and the rest of the Venetian painters. This custom, or mode of operation, implies at least a true taste of that in which the excellence of colouring consists, which does not proceed from fine colours, but true colours,—from breaking down these fine colours, which would appear too raw, to a deep-toned brightness. Perhaps the manner in which Correggio practised the art of glazing was still more like that of Apelles, which was only perceptible to those who looked close at the picture, '*ad manum intuenti demum appareret*;' whereas in Titian, and still more in Bassan and others, his imitators, it was apparent on the slightest inspection."

Greek painting at its best, there cannot be much doubt, was only a little, if at all, inferior to the sculpture of the same period. The men who saw and appreciated the one admired equally the other. The paintings, equally with the statues, were praised for their grandeur of thought and expression, for their nobleness of design, and accuracy of imitation. Foreshortening and perspective, essential qualities in a picture, were understood and practised. So also were the laws of light and shade, though that disposition of light and shadow in masses, which modern writers call *chiaroscuro*, was probably unknown. Colour, as we have seen, was studied in its subtlest refinements. Whether, as Sir Joshua Reynolds expressed his assurance, "if what has happened in the case of sculpture, had likewise happened in regard to their paintings, and we had the good fortune to possess what the ancients themselves esteemed their master-pieces, we should find their figures as correctly drawn as the 'Laocoon,' and probably coloured like Titian," we cannot venture to say. We have none of their master-pieces; but the works brought to light since Reynolds wrote, though at best only such as were executed in the decline of art for decorating the provincial residences of affluent foreign patrons, suffice fully to justify his sanguine anticipations. The finest ancient picture yet discovered is that known as 'The Battle of Issus,' found at Pompeii in 1831, and now in the Museo Borbonico at Naples. It displays great skill in design, knowledge of foreshortening and perspective, and immense vigour of expression, though the execution is inferior to the conception. This is a mosaic, but was probably a copy in imitation of some celebrated painting of an earlier date, as the chief extant remains of Græco-Roman sculpture are known to be copies of famous old statues. Another mosaic of admirable design is that of the Choragus engraved under MOSAIC. The finest extant painting of Græco-Roman date is that known as the 'Abdobrandini Marriage,' found originally on the Esquiline Mount, and now in the Vatican—a fresco-painting executed with great freedom, and excellent both in composition and colour. Equally remarkable in their way are the paintings of 'Achilles Discovered by Ulysses,' found in the House of Castor and Pollux at Pompeii (Zahn, ii., pl. 23); an 'Achilles in a Quadriga,' painted in monochrome; and a 'Dirce attached to the Bull,' found in the House of the Grand-Duke at Pompeii in 1833, and, like the preceding, engraved in Zahn. Many others might be mentioned which, if regarded as they ought to be, as late and feeble imitations, would attest sufficiently the high character of Greek painting when in its more flourishing condition. (See engravings in Müller, 'Denkmaler der Alten Kunst;' D'Agincourt, 'Hist. de l'Art par ses Monumens;' Mazois, 'Pompèi,' tom. iv.; the 'Mus. Borbonico;' and Zahn, 'Die Schönsten Ornamente und merkwürdigsten Gemälde aus Pompeii, Herculaneum, und Stabiae.')

Painting in Rome.—The Romans had no independent school of painting. We have spoken of the early connection of Greece with Italy and with Magna-Græcia, and the later migrations of Greek painters into Rome. It was by these mainly, if not exclusively, that the pictures painted in Rome and the provinces were executed, and of which examples remain in the frescoes and mosaics exhumed at Rome, Pompeii, and elsewhere. Pliny, however, speaks of certain Romans who cultivated painting long before Greek pictures were brought to Rome. C. Fabius Pictor is said to have derived his name from decorating the temple of Health (A.U.C. 450, B.C. 304). The poet Pacuvius (B.C. 219-140) was an artist. The victory of L. Scipio over Antiochus (B.C. 190) was recorded by a picture in the Capitol, as that of M. Valerius Messala over Hiero had been by an historical painting in the Curia Hostilia (B.C. 264). The first foreign picture publicly exhibited at Rome was after the sack of Corinth by Mummius (B.C. 146), an event which brought many of the finest works of art to the conquering city, however little the victors were qualified to appreciate their real worth. At a later period we hear of Arellius, Amulius, Accius, Priscus, and Ludius, of whom the last, in the time of Augustus, painted landscapes, garden scenes, and buildings on the walls of rooms, such as we see in the ruins of Pompeii or the remains of the palace of Nero. Cæsar purchased the 'Ajax' and the 'Medea' of Timomachus for 80 talents, and at his time a school of some eminence existed at Cyzicus. The forced bloom of art which characterises the age of Hadrian implied a momentary revival of painting, and Action (of whom Lucian speaks so highly) must probably be reckoned as his contemporary.

When Pliny wrote (about A.D. 75), painting was already an expiring art (*artis morientis*); the most splendid colours, he says were used, but nothing worth looking at was produced. Mural painting was chiefly practised, the painting being executed in a light rapid manner, and the subjects such as would surprise the spectator by some trick of art. Grotesques and fantastic architectural and landscape designs formed the decorations of apartments; or gay and brilliantly coloured mythological subjects mingled with grotesque borders and garlands of flowers on roofs and walls. The best pictures were those which aimed at the reproduction of the more celebrated works of earlier artists. We have the names of many painters of this age of decrepitude, but they are names only; the art was felt to be so fallen that the artists themselves were despised, and painting came at length to be the occupation of slaves and men of slavish minds. The last embers of native power were extinguished amidst the turmoils of civil dissensions, and the inroads of foreign barbarians.

For further information on the painting of the ancients, see Müller, 'Handbuch der Archäologie der Kunst;' Bottiger, 'Ideen zur Archäologie der Malerei;' Raoul-Rochette, 'Recherches sur l'Emploi de la Peinture;' and 'Peintures Antiques;' Junius, 'de Picturâ Veterum;' and Sillig's 'Catalogus Artificum;' Thiersch, 'Ueber die Epochen der bildenden Kunst unter den Griechen;' and Mr. Wornum's article, 'Pictura,' in Smith's 'Dictionary of Greek and Roman Antiquities,' with the authorities there cited.

Mediæval painting.—From the ashes of this extinct ancient art arose a new form, which our zealous modern mediævalists have distinguished with the name of Christian art. But as it was chiefly Christian inasmuch as it was the art of the priest and the cloister, it might with equal justice have been designated Monastic, or Ecclesiastical Art, if it had been intended to mark its origin or application; while from its being nearly coincident in duration with the period known as the middle ages, its date is more specifically indicated by the older phrase, Mediæval Art, and its source, as far as painting is concerned, by that of Romanesque or Byzantine. As, however, the term Christian Art has found pretty general acceptance, it may without inconvenience be employed indifferently with either of the others.

In the first centuries, however, Christianity was too uniformly oppressed to require the blandishments of art; and the Judaic notions of a large proportion of its professors would probably have prevented them from calling in the assistance of painting for the decoration of their places of worship, or for recording the events and miracles of their faith, even had they been at liberty to do so. The earliest examples of art applied to Christian purposes occur in the catacombs of Rome [CATACOMBS], where, on opening those vast subterraneous vaults in the early part of the 17th century, the sides and roofs were seen to be almost covered with paintings and inscriptions; and numerous sarcophagi bore similar examples of the sculptor's chisel. The effects of air and damp, and the smoke of numberless torches have combined to obliterate the paintings left *in situ*, but a large proportion of them will be found engraved as well as described in the works of Aringhi, Bosio, Bottari, and Bunsen, on Subterranean Rome, in D'Agincourt's 'Hist. de l'Art,' and Maitland's 'Church in the Catacombs;' while as many as were removable of the painting themselves, and carefully executed copies of others, have been collected and placed in the Vatican and in the palace of St. John Lateran at Rome. As might well be supposed from their place, no less than their age, these works are extremely rude and inartistic; and at times they exhibit a rather incongruous adaptation of heathen symbols and personages; but on the other hand, some excellent critics discover in them much grandeur of arrangement, and a "peculiar solemnity and dignity of style." (Kugler, 'Handbook of Painting: Italy.')

From the removal of the seat of empire to Constantinople, Rome ceased to be even nominally the centre of the arts, though that there were undoubtedly native painters in Rome, as well as in other parts of Italy, down to the revival of painting in the 13th century, is certain, from the remains still extant in many cities of Italy; from the illuminations in manuscripts [MINIATURE]; from the Mosaics [MOSAICS]; from the painted series of popes in the Basilica of St. Paolo, commenced in the 5th century by order of St. Leo, and from other evidence. For above two centuries Byzantine art differed in no essential respect from that of Rome. It was not till about the reign of Justinian that Byzantine art arrived at its full development; but thenceforward, Byzantium remained, till the great revival of painting in Italy in the 13th century, the grand central school which supplied artists, works of art, and the laws by which they were judged, to all parts of Europe. But art itself was now at almost its lowest ebb. The works produced were chiefly for churches or religious purposes. All traces of the traditions of the ancient schools seem to have been lost, though some desire to imitate ancient forms was retained. Something of the oriental love of gold and bright colours appears to have been engrafted on the western modes of working. The figures were ill-drawn, rigid in character, ungainly in position, long and meagre in their proportions, and devoid of all reality. The colours, though bright, were raw and crude, and commonly painted on a gold background. Enormous mosaics or frescoes of the St. Saviour, and figures of the saints, of the most strictly conventional type, were placed in all the churches. Individuality of style was entirely ignored. The same characteristics occur in Byzantine paintings, mosaics, and miniatures wherever found. And the same characteristics have distinguished the school down to the present day: for in Greece and Russia, and wherever in fact the Greek church exists, religious pictures of precisely the same type have continued to be manufactured. M. Didron (‘Manuel d'Iconographie,’ p. ix. &c.), on visiting the monastery of Mount Athos, now the principal manufactory for pictures for the Greek churches throughout the world, saw painters engaged in the execution of pictures according to a strict and singularly minute code of laws, ‘Ἑρμηνεία τῆς Ζωγραφικῆς’ (‘Guide for Painting’), a copy of which he with some difficulty procured, and of which translations have been published in French by M. Durand, and in German by Dr. Schäfer (‘Das Handbuch der Malerei vom Berge Athos). To such mechanical perfection had the painters, whom M. Didron saw at work, attained—each man taking his own part of the picture—that he actually witnessed the Monk Joasph and five assistants paint in fresco entirely from memory, without cartoons, tracings, or any other mechanical aid, a picture of Christ and the Eleven Apostles, all the size of life, in the space of an hour! This swiftness and certainty of execution are the result of the training and experience of centuries directed upon unchanged repetitions; but we have here only an exaggeration of mediæval Byzantine art with all its soulless traditional design and absence of thought, imagination, and individuality. The art of Byzantium is best seen in MINIATURES and MOSAICS, to which headings we refer the reader for further information.

Revival of Painting in Italy.—The Ostrogoth dominion was not unfavourable to art; at least there is a studied affectation of classical knowledge in Cassiodorus, and the mutilators of ancient statues are denounced as criminals. The Lombards could have brought no art with them, and were unlikely to appreciate what they found. The most remarkable monument of their time is the large MS. of the Bible from Mont Amiata, still preserved in the Laurentian Library at Florence; but others scarcely less beautiful are not uncommon. [MINIATURE.] The union of the Church with the Frank Empire gave the popes greater leisure and means, and Rome became once more a capital.

It is probable that the conquest of Constantinople by the Latins in 1204 supplied to the Italians some of that technical skill which the wild conflicts of their own parties at home had contributed to obliterate. Numerous Greek artists settled in the cities of Italy, and a semi-Byzantine style is visible in the painting as well as in the architecture of Venice, Pisa, and Siena.

But native painters of remarkable talent arose, first perhaps in the last named city, who soon cast off the trammels of Byzantine tradition, and painting once more rose to the dignity of a fine art, assuming a position such as it could only have previously held when the arts of ancient Greece were in their most flourishing state. We shall be able to trace the history of painting in Italy most conveniently by noticing in succession the principal Italian schools of painting. (The term school of painting is explained under BOLOGNESE SCHOOL OF PAINTING.)

Tuscan School of Painting.—This is frequently called the *Florentine School*, and is divided into several epochs, the first of which is termed the old Florentine; but the school of Florence was not the school of Tuscany until after the time of Michel Angelo. In the earliest period of painting in Tuscany the principal painters were of Pisa and Siena, and there is characteristically no essential difference between their works and those of the early painters of Umbria of the same period. Sienese critics have discovered a distinct school in the works of the old masters of Siena, but it would be difficult to show any other distinction than a mere difference of local origin.

Some artists of Siena and Florence, of the early part of the 13th century, are the oldest painters of Tuscany that are known. There were painters in Pisa before this time, in the 11th century, but they were Greeks from Constantinople: and there are paintings extant in Tuscany which are said to be of the same period, but they are probably the production of Greek artists. In the church della Trinità at Florence there is a picture of Christ painted upon canvas, and glued upon a wooden cross, which is probably of the 10th century; it was done before 1003: and in the church of San Miniato al Monte near Florence there is a Greek painting of San Miniato Martire, of the 11th century. (‘Etruria Pittrice.’)

The first considerable efforts towards the revival of painting were made by the Tuscans, and the Tuscan painters throughout have done much towards its improvement and perfection in later periods. The following masters are among the most celebrated in the history of painting, both for their works and for the great changes they effected in the prevailing styles of their respective periods: Giotto di Bondone of Vespignano (b. 1276, d. 1336); Tommaso Guidi, of San Giovanni, called Masaccio (b. 1401 or 1402, d. 1443); Lionardi, of Vinci (b. 1452, d. 1519); Michel Angelo Buonaroti, of Castell' Caprese, in the diocese of Arezzo (b. 1474, d. 1563); Ludovico Cardi, of Cigoli (b. 1559, d. 1613); and Pietro Barrettini, of Cortona (b. 1596, d. 1669). All these painters, through the striking characteristics of their respective styles, made epochs in the history of painting in Tuscany.

The oldest Tuscan artists whose names are known are Niccola and Giunta of Pisa. [PISANO, in BIOG. DIV.] Niccola Pisano, or of Pisa, was a sculptor, and the first restorer of design from the excessive rigidity of the Byzantine forms; he endeavoured to imitate the style of a bas-relief upon an ancient sarcophagus at Pisa: he lived at the beginning of the 13th century. Giunta Pisano is the earliest Tuscan painter to whom extant works have been assigned: he is said to have learnt painting of some Greeks who were at Pisa about the year 1210. In 1230 he was employed in the church degli Angeli at Assisi: there are a crucifixion and some other figures painted upon a wooden cross, the colours of which are mixed in some medium not affected by water. The drawing is careful, but very dry, and the fingers are extremely long—faults, as Lanzi has observed, not of the men, but of the times. The expression in the heads, however, is good, the draperies are well arranged and the colouring, though brown, is laid on with a strong impasto. Some frescoes by Giunta are in the upper church of San Francesco at Assisi.

Contemporary with Giunta of Pisa, were Guido of Siena and Buonaventura Berlinghieri of Lucca. The former was illuminator and painter: a Madonna in the Malevolti chapel in the church of San Domenico at Siena, engraved in Lastri's ‘Etruria Pittrice,’ has very great merit for its period. Siena had many other painters about this time, and they were even constituted as a civil body in 1250. Ugolino of Siena, says Vasari, painted pictures and chapels in every part of Italy; he died at an advanced age in 1339. Buonaventura Berlinghieri of Lucca painted in 1236; there was also a Diodato of Lucca, who was living in 1288.

A very superior painter to those already mentioned, and one who added also much to the practical technic of painting, was Margaritone of Arezzo, an older painter than Cimabue. At the church of Santa Croce, at Florence, there is a crucifixion by Margaritone, which is placed near one by Cimabue; and although Margaritone's is less finished in execution than Cimabue's, the difference is not so great that the title of painter should be denied to the former if given to the latter. The portrait or picture of San Francesco di Assisi in the church of Sargiano, near Arezzo, dressed in the habit of a monk, with all the faults of the time, has a grand expression, and is a very remarkable production; it is marked Margarit' de Aretio *pingebat:* an inscription which probably indicates a Greek source of instruction, directly or indirectly.

The earliest painter in Florence was apparently Maestro Bartolomeo, who painted in 1236. An Annunciation, which he painted in the church de' Servi, has been attributed to Cavallini, the scholar of Giotto. Another predecessor of Cimabue was Andrea Tafi, born in 1213; he was the scholar of Apollonius, a Greek, whom he assisted in some mosaics in San Giovanni, at Florence. Vasari terms Tafi the first restorer of mosaic in Tuscany: he was also a painter.

A painter of somewhat more merit and much more fame than any of the preceding, was Giovanni Cimabue, born at Florence in 1240, through the partiality of Vasari, or his neglect of research, commonly called the father of modern painting. He was architect and painter; he greatly improved the proportions of the human figure in design; inspired his figures with more life than his predecessors; and excelled them in grace of execution and in richness of colouring: his works are, notwithstanding, strictly of the Byzantine style. Cimabue is said by some to have learned painting of Giunta Pisano, whom he assisted in his frescoes at Assisi, in 1253, in his thirteenth year; Vasari says that he learned of some Greeks who were employed to decorate the church of Santa Maria Novella at Florence. One of his earliest and most remarkable pictures is the Colossal Madonna, now in the Academy at Florence, formerly in the church of Santa Trinità; but his greatest works are those in the upper church of San Francesco at Assisi. Cimabue excelled chiefly in male heads, to which he has sometimes given a truth and grandeur of expression that have never been much surpassed. Contemporary with Cimabue, but somewhat younger, was Ducio di Buoninsegna of Siena, famous in his time: he painted great works in the cathedral of that place, which are in part still extant: also a remarkable altar-piece for the same church, which is still preserved there; it was painted in 1308 and 1311, and when completed was carried in procession to the cathedral. It was painted on both sides, but is now cut into two. One side, the former front, is a Madonna and infant Christ, surrounded by angels; on the other side, or former back, there is a series of small pictures illustrating the history of the Passion, all containing many figures, executed with surprising industry, skill, and judgment, when compared with the majority of the works of his contemporaries.

Gaddo Gaddi of Florence, born in 1239, was also one of the most distingushed artists of this period. He was celebrated for his works in mosaic, of which there are still specimens in the cathedrals of Florence and of Pisa. He worked also at Rome, but the great mosaics of St. John Lateran and in Santa Maria Maggiore are the work of Mino da Turrita, an earlier master, and the most celebrated of his time. The mosaics of the tribune of San Giovanni at Florence were executed by Turrita, who finished them in 1225.

That of discovering and cultivating the abilities of Giotto was not one of the least services of Cimabue. [GIOTTO, in BIOG. DIV.] Giotto surpassed all his predecessors, and he added as much to the art of his master Cimabue as Cimabue had added to that of the Greeks. In the mature works of Giotto there are no traces of the Byzantine style: they made an epoch in painting; and from his time Florence dates its preponderance in the history of Tuscan art. If Cimabue, says Lanzi, may be termed the Michel Angelo of his age, Giotto may be termed its Raffaelle. Great as was the fame of Cimabue, says Dante, it was rendered obscure by that of Giotto. Dante and Giotto were friends, and the great poet celebrated the painter in some well known lines ('Purgatorio,' xi. 32).

Giotto was painter in history, miniature, portrait, and in mosaic; also a sculptor and an architect: the celebrated Campanile of Florence is his work. He painted in many cities of Italy, but his chief works are those in the lower and upper churches of San Francesco at Assisi. In these paintings there are heads worthy in expression of the greatest masters that have succeeded him; yet, notwithstanding his great merits, his design is extremely hard and Gothic, especially in his large figures: he paid also little attention to perspective or to chiaroscuro; and although he brought painting far from its infancy, he still left it upon the whole as far from its maturity.

The scholars and imitators of Giotto were very numerous: the principal of them were Stefano Fiorentino, Tommaso di Stefano, called Giottino, and Taddeo Gaddi, the son of Gaddo Gaddi. These painters worked in the same style as Giotto, sometimes inferior and sometimes superior in execution. Stefano was called the ape of nature, "Scimia della Natura." Taddeo Gaddi, says Vasari, excelled Giotto in colouring and in tone: his principal works were painted in the church of Santa Croce; and in the chapel Degli Spagnuoli, in the church of Santa Maria Novella. The pictures of the three saints seated, in this chapel, are magnificent in the character of the heads and in the style of the draperies: they represent San Dionysio Areopagita, San Pietro Lombardo, and San Severino Boezio: they are engraved in Lastri's 'Etruria Pittrice.' Contemporary with Giotto was Buonamico di Cristofano, called Buffalmacco, the scholar of Andrea Tafi; and Bernardo and Andrea Orcagna, who painted together a heaven and a hell in the Struzzi chapel in the church of Santa Maria Novella; and in the Campo Santo at Pisa, Andrea painted a Last Judgment, and Bernardo a Hell. In the church of Santa Croce also Andrea painted similar scenes: amongst the blessed he placed his friends, and amongst the damned his enemies. The best preserved works of Buffalmacco are at the Campo Santo at Pisa.

Two celebrated scholars of Andrea Orcagna were Bernardo Nello of Pisa and Francesco Traini of Florence: of the latter there is a celebrated picture of Thomas Aquinas at Santa Caterina at Pisa.

Contemporary also with Giotto was the famous Simone Memmi di Martino of Siena, celebrated by Petrarch in two of his sonnets for a portrait of Laura. Simone was born about 1284, and after distinguishing himself by many works in various cities in Italy, he went to Avignon, where he died in 1344. He excelled in composition and in invention. Vasari speaks very highly of his great works in the chapel Degli Spaguoli, in the church of Santa Maria Novella at Florence, which was painted in 1332. Christ going to Calvary, which is one of the paintings of this chapel, is a work of great merit in expression, in composition, and in design. (Lastri, 'Etruria Pittrice.') There is in the Ambrosian Library at Milan, a MS. of Virgil with the commentary of Servius, which belonged to Petrarch; and on the frontispiece is a miniature of Virgil writing, with various characteristic accessories, by Memmi: it is supposed to have been painted for Petrarch, and that the poet wrote the following lines attached to it:—

"Mantua Virgilium qui talia carmina finxit;
Sena tulit Simonem digito qui talia pinxit."

Shortly after the death of Giotto, in 1336, painters commenced to be extremely numerous in Tuscany. In the year 1349 the painters of Florence formed themselves into a society under the name of Compagnia di San Luca (Company of St. Luke). This society was not however composed exclusively of painters: it contained various artists in metal and in wood, in whose business ornamental design was in any way concerned. A similar institution, but on a greater and more permanent plan, was established at Siena in 1355.

Other distinguished painters of this period were—at Siena, Lippo Memmi, Cecco di Martino, Ambrogio Lorenzetti, and Bernardo or Berna da Siena. At Florence were Giovanni and Angelo Gaddi, the sons of Taddeo Gaddi. Angelo Gaddi was an excellent colourist; but he was content to imitate the works of Giotto and of his father. His scholar Cennino Cennini was also a good colourist. The following also are deserving of mention: Starnina, Dello Fiorentino, Jacopo di Casentino, Spinello Aretino and his son Pari Spinelli, Lorenzo di Bicci and his son Neri, also Giovanni di Niccolo of Pisa, who all painted more or less in the style of Giotto, as did likewise all the artists of Tuscany, until a better taste was spread by the works of Masaccio.

In the 15th century, when the Medici established themselves as the rulers of Florence, and that city gradually extended its power over the neighbouring territories, and became the capital of Tuscany in matters of art as well as of state, the arts were in a manner rendered dependent upon the caprices or tastes of its princes; and as the Florentine artists, through extended patronage, gradually evinced more activity, and acquired as a body a greater importance, those of Siena and Pisa proportionably declined in both respects. The improvements made in painting at this period were very great, and one of the most essential was the commencement of a proper application of perspective: the chief promoters of this science were Pietro della Francesca and Paolo Uccello; the latter comparatively neglected every other department of painting for the study of perspective. There is in the first cloister of Santa Maria Novella a picture of the Drunkenness of Noah, by Uccello, in which he has displayed his ability in this respect: Noah is violently and well foreshortened. Another department of painting which had been neglected by the school of Giotto was chiaroscuro. This was first attempted with success by Masolino da Paincale, who executed some excellent works, for the period, in the chapel of San Pietro in the church del Carmine. Masolino is also not less distinguished for having been the master of the celebrated Masaccio, who, if any individual is entitled to this distinction, can alone be styled the father of modern painting.

That many of the painters however who preceded Masaccio had great ability, even for any period, is certain; and it is also certain that they had recourse to the study of nature—a fact which proves that the mere study of nature, without the knowledge of what to select for imitation, will not lead to the production of fine forms. And although beautiful forms have been produced by the earlier painters, it is the accident of the model, and not the result of choice; for we sometimes find the finest parts associated with others so inferior, that from their juxtaposition the whole has an appearance of deformity, which arises both from the inequality in individual models, and from the painter's occasionally trusting his own knowledge and occasionally having recourse to the model. This imperfection could only be avoided by the adoption of a standard of form, which should preserve a unity of style in every degree—a standard which, experience has shown us, it would require centuries to attain simply by the study of nature, because of the infinite varieties of form met with in individuals. This standard however already existed in the antique, and it required only the master-mind to appropriate it; and to have been the first to do this efficiently constitutes the great merit of Tommaso Guidi, commonly called Masaccio, on account of the slovenliness of his personal appearance. Masaccio introduced a style of composition and design which until the appearance of Da Vinci and Michel Angelo experienced no material change. Da Vinci and Fra Bartolomeo enlarged upon Masaccio's style. Michel Angelo invented a style of his own, and he outlived it. The style of Masaccio, however, expanded to its utmost, still lived in the works of Raffaelle and the principal painters of the Roman school. Yet the great improvement in design which was accomplished in the works of Masaccio was not entirely his own merit; for Ghiberti and Donatello had made great advancement in sculpture; and Gentile da Fabriano and Vittore Pisanello, with whom Masaccio became acquainted in Rome, had made great improvements upon the Giottesque school in painting. Masaccio's greatest works are in the Brancacci chapel in the church of Santa Maria del Carmine at Florence: they have been engraved by Lasinio and others. Masaccio died before the completion of these works, in 1443, in his forty-first or forty-second year, not without suspicion of having been poisoned. Many of his works have perished. His most able contemporaries and followers were Fra Giovanni da Fiesole, Benozzo Gozzoli, and Fra Filippo Lippi, the best painter of his time; he completed the works of Masaccio in the Brancacci chapel: he died in 1469. There are in his works much of that mellowness of colouring and harmony of light and shade which characterise the works of Fra Bartolomeo and Leonardo da Vinci. In the gallery of the Academy at Florence there are some beautiful specimens of the works of Lippi.

Other painters of great ability of this period, both in oil and in fresco, were Andrea del Castagno, called the infamous; Sandro Botticelli, Filippino Lippi, Raffaellino del Garbo, Domenico del Ghirlandajo, Cosimo Roselli, Piero di Cosimo, Antonio Pollaiuoli, the first Italian painter who studied the dead subject for the purposes of design; Andrea Verocchio, and Luca Signorelli of Cortona. There were also many others of merit of this school at about the end of the 15th century, but they followed only in the steps of others.

The works of Lionardo da Vinci, and the painters who imitated or adopted the chief characteristics of his style, constituted another epoch in the history of painting; but their influence was not confined to Florence or to Tuscany; it was greater in Milan and in Lombardy than in Florence. The fulness however and vigour of design which distinguish the works of Fra Bartolomeo, and even Michel Angelo, characterise in an equal though somewhat different degree also the works of Da Vinci, and are combined with an exquisite finish and harmony of tone which are peculiar to himself. Lionardo was born at Vinci in 1452, and learnt painting of Andrea Verocchio, who, upon seeing the superiority of his scholar, forsook that art for statuary. Lionardo was painter, sculptor, architect, engineer, mathematician, writer, musician, and poet; he is however chiefly known as a painter. Historians have divided his career into four periods; he painted at first in the manner of Verocchio, and his pictures of this time are lighter in style of design, and have less strength of chiaroscuro, than his later works. His second period was that spent at Milan in the service of the Duke Sforza, when he painted his Last Supper. The third was his great Florentine period, from 1500 to 1512, when he executed the famous cartoons of Santa Anna, and of the Battle of Niccolo Piccinino, called the Battle of the Standard; and his own portrait in oils, which is in the gallery at Florence—a work which for painting cannot be surpassed. In the fourth period he was comparatively inactive. In

1512 he returned to Milan; in 1514 (Vasari says 1513) he visited Rome; and in 1516 he went with Francis I. to France, where he died, at Fontainebleau in 1519, aged 67. [VINCI, in BIOG. DIV.]

When Da Vinci returned in 1500 to Florence, the only painter there of extraordinary ability was Fra Bartolomeo di San Marco, or Baccio della Porta, commonly called Il Frate, then in his twenty-ninth year. Michel Angelo was at that time in his twenty-sixth year only, and had done nothing in painting, having confined himself up to that time nearly exclusively to sculpture; which rendered the more remarkable his great success in 1506, in the so-called cartoon of Pisa, executed by order of the gonfaloniere Pietro Soderini, for one end of the council-hall of the old palace of the Signory, for the other end of which Da Vinci made his cartoon of the Battle of the Standard, in which a group of horsemen were contending for some colours, with various accessories.

The good effects of the munificence of Lorenzo de' Medici and his encouragement of the arts did not completely show themselves until after the second restoration of the Medici in 1512. Lorenzo established an academy in his garden near the church of San Marco, and formed a splendid museum of ancient and modern works of art: it was the nursery of all the great artists of Florence of the early part of the 16th century. Some singular scenes were enacted by Savonarola during his short triumph over the general order of things. In 1497, at the time of the Carnival, instead of the usual bonfire in the market-place, Savonarola had a large scaffolding prepared, and upon this he piled many of the most excellent works of the Florentine artists, both in painting and sculpture, including the busts and portraits of several beautiful Florentine females, with many foreign tapestries, condemned on account of their nakedness; and they were all burnt amidst the rejoicings of the populace. In 1498, the following year, he repeated the scene on a much greater scale: on this pile was burnt an illuminated copy of Petrarch. Fra Bartolomeo, Lorenzo di Credi, and other distinguished painters, took part in this fanatical destruction.

Fra Bartolomeo imitated, or rather painted in a very similar style to, Lionardo da Vinci. Several of his works are in many respects admirable, and in composition, in expression, in the cast of draperies, and in design, bear the strongest resemblance to the works of Raffaelle: the great figure of St. Mark, in the Pitti palace, combines with the style of Raffaelle much of the grandeur of the prophets and sibyls of Michel Angelo in the Sistine chapel. Bartolomeo was the true master of Raffaelle: these two great painters contracted a friendship for each other in 1504, when Raffaelle was in Florence and only twenty-one years of age. Bartolomeo died in 1517, three years before Raffaelle. Mariotto Albertinelli followed the style of Bartolomeo, and painted many excellent pictures.

Andrea Vannucchi, called del Sarto from the trade of his father (a tailor), was also one of the most distinguished of all the Florentine painters. He was the scholar of Piero di Cosimo, and had great ability of execution, but he wanted invention. His style in colouring and in chiaroscuro is similar to that of Fra Bartolomeo, but from the study of the cartoon of Pisa he had acquired much of the style of Michel Angelo in design. His easel pictures are very numerous. He died in 1530.

Michel-Angelo Buonaroti, painter, sculptor, and architect, the scholar of Domenico Ghirlandajo, revolutionised painting not only in Tuscany, but in Italy, yet although his style can scarcely be said to have anything in common with that of any of his predecessors, he was anticipated in some of the greatest beauties of composition and design by Da Vinci and by Raffaelle. The chief characteristics of his works are severe grandeur of design and an occasional sublimity of invention: the frescoes of the vault of the Sistine chapel, painted in 1512, are in these respects unrivalled by any other works. The cartoon of Pisa, however, was by some contemporary critics considered to be a superior work in design: it represented many soldiers of Pisa suddenly called to arms when bathing in the Arno, and was a very superior work to the rival cartoon of Lionardo da Vinci. Benvenuto Cellini calls these cartoons the school of the world, so long as they were exhibited to the public: Vasari speaks to the same effect. They were both lost a few years after they were made, in a manner never accounted for. Michel Angelo's was cut in pieces. There is an old print of Lionardo's by Edelinck, made from a bad drawing; and Marcantonio and Agostino Veneziano both engraved parts of Michel Angelo's. The style of Michel Angelo has its faults, independent of an excessive muscular development: he had but one standard of form for man, woman, and child, of every age and every degree; his women are female men, and his children diminutive giants. His great works are his single figures, but his paintings are as statuesque as his statues, and express a similar character: his Moses, his Lorenzo de' Medici, in sculpture; his Daniel, and his Jeremiah or Isaiah, in painting. His Last Judgment, a vast work, but the production of his old age, has the faults of his other works without their grandeur or sublimity; it was finished in 1541, in his 67th year. Michel Angelo made many drawings, but he painted scarcely anything in oil. Though the great works of Michel Angelo were executed at Rome, they influenced chiefly the Florentine school; and the painters of Florence, unlike those of Rome, not being held in restraint in their imitation of Michel Angelo by any veneration for the works of Raffaelle, the imitation was the more palpable, and it was an imitation of *manner* only, not of *style*. The anatomical school is the best designation for the Florentine imitators of Michel Angelo. Francesco Granacci and Daniel Ricciarelli of Volterra, were the least mannered of his scholars. The latter painted with great care, and his Descent from the Cross, in the church of Trinità de' Monti, is reckoned one of the finest pictures in Rome. Another celebrated follower of Michel Angelo was Giorgio Vasari; he is better known however for his lives of the painters, sculptors, and architects, than for his paintings. He executed an immense number of works, but beyond a general correctness of drawing they have nothing to recommend them. Other followers and imitators of his style were Sebastiano del Piombo, Marcello Venusti, Federigo Zuccaro, Francesco Rossi de' Salviati, Jacopo del Conte, Angelo Bronzino, and Allessandro Allori. Painters of this period who were not carried away with the host of imitators were Franciabigio, Jacopo da Pontormo, and Domenico Puligo, scholars of Andrea del Sarto; besides some others of less note: also Il Rosso, or Maitre Roux, as he is called by the French.

At the end of the 16th century a new style was introduced by Ludovico Cardi, commonly called Cigoli, which combined careful drawing with brilliant colouring. Santi di Titi preceded him in his indifference towards the anatomical school, and he was greatly assisted in establishing his own style by Gregorio Pagani and Domenico da Passignano. This school was founded upon the style of Baroccio and that of Coreggio, and had much in common with the eclectic school of the Caracci. Its ascendency was promoted by the works of the Venetian Ligozzi at Florence, and by the school of Francesco Vanni at Sièna. These painters were followed by younger artists, by Giovanni Biliverti, Fabrizio Boschi, Christofano Allori, Jacopo da Empoli, Giovanni Battista Vanni; also Matteo Roselli and his scholars Giovanni Manozzi da San Giovanni, Baldassare Franceschini, called Il Volterrano, and Francesco Boschi, an excellent portrait-painter; likewise by Francesco Turini and his scholar Simone Pignone; and Lorenzo Lippi, like his friend Salvator Rosa, poet and painter.

Also in a somewhat similar taste of colouring and design, though in a very different style of execution, painted Carlo Dolci; his elaborate finish however is the principal merit of his works; his colouring is often green, yet some of his female heads are executed in exquisite taste. He died in 1686.

In about the middle of the 17th century another change took place in the style of the Florentine painters, as well as in that of the Roman, through the extensive and attractive works of Pietro Berrettini da Cortona, in Florence and in Rome. Cortona was invited to Florence about the year 1637, and was occupied for several following years over his great allegorical frescoes in the Pitti Palace; he left them however unfinished: they were completed by Ciro Ferri, his most distinguished follower. In Florence the style of Cortona attained completely the ascendency, and prevailed the whole of the 17th century and the greater part of the 18th. Cortona paid little attention to expression; his object was to produce a grand effect on the whole: his style was decorative, and his works will not bear inspection in the parts. He is the head of those artists called machinisti by the Italians. His principal followers in Florence were the three Dandini and their scholars, Antonio Domenico Gabbiani and others, and his scholar Benedetto Luti; also Salvi Castellucci, Giacinto and Ludovico Gimignani, Lazzaro Baldi, Allessandro Gherrardini, and Sebastiano Galeotti. Two of the most distinguished Florentine artists of the end of the 18th century were Gio Battista Cipriani and the landscape-painter Francesco Zuccherelli, who both spent some time in this country: also Tommaso Gherardini, who died in 1797, and Pietro Pedroni, who died in 1803, are reckoned among the best painters of their period.

Venetian School.—The historians of Venetian art date the commencement of modern painting in Venice from the 11th century, or about 1070, when the Doge Selvo invited some Greek mosaic-workers to Venice to adorn the church of St. Mark; and in the 13th century, after the taking of Constantinople by the Venetians, in 1204, not only works of art, but artists also, are said to have been plentiful in Venice, Venetians as well as Greeks; only two however of the former can now be named, Giovanni da Venezia and Martinello da Murano. On an old wooden sarcophagus of the Beata Giuliana, in the monastery of San Biagio alla Giudecca, there is a painting of about the year 1262; but the painter's name is not known: it is in a rough style, but Lanzi is of opinion that it is not Greek.

It was not until after the time of Giotto, who executed some works in Padua and Verona in the beginning of the 14th century, that the painters of the Venetian states began to make themselves known by their works. The oldest known works at Padua are by painters of the school of Giotto. The extensive paintings in the church of San Giovanni Battista at Padua are attributed to Giusto Padovano, a scholar of Giotto and a Florentine by birth, though naturalised at Padua. Guariento of Padua was also a follower of Giotto, and was celebrated about 1360: some of his works are still remaining. There are also some works still extant of two celebrated Veronese painters of the same time: of Alticherio da Zevio, near Verona, in the old church of San Giorgio, illustrating the life of St. James; and others of the life of St. John by Sebeto of Verona, in the same church, much in the style of Giotto, especially the former. To these may be added a Jacopo of Verona, who painted some frescoes in San Michel at Padua; and a Gio. Miretto of Padua, who executed some works in the great hall of that place. There were however some painters about this time in Venice and Treviso who painted in what may be termed a national style; and among these may be included the miniature-painters, who were numerous at this time. Among these Zanetti mentions a Maestro Paolo, whose name he found recorded in an ancient parchment with the date of 1346. He is the earliest of the Venetian painters whose time and name are known: there is in the church of St. Mark a picture, or ancona, as it is called, by him and his two sons, divided into several compartments, illustrating the history of our Saviour, with the following inscription:—"Magister Paulus cum Jacobo et Johanne filiis fecit hoc opus." Lanzi says his style reminds us much of the Greek specimens of art. There is another painting by him in the sacristy of the Padri Conventuali at Vicenza, inscribed as follows:—"1333, Paulus de Venetiis pinxit hoc opus." One of the earliest Venetian painters also was a Lorenzo of Venice, who according to Zanetti, was paid 300 gold ducats for an altarpiece, formerly in the church of Sant' Antonio di Castello, now in the Academy, on which is his name and the date 1358. There is likewise in the house of the Ercolani family at Bologna a picture inscribed "Manu Laurentii de Venetiis, 1368:" he was also most probably the painter of the fresco of Daniel in the Lion's Den, in the church of Mezzaratta, near Bologna, marked Laurentius, P.: it was painted about 1370. Another Venetian painter of this time was Niccolo Semitecolo: his name is inscribed as follows upon a painting in the Chapter Library of Padua:—"Nicoleto Semitecolo da Veniexia impense, 1367." This work is a good specimen of the school: it represents the Trinity with the Virgin, and some stories of St. Sebastian: the nude is tolerably well expressed, and the design is bold; but it bears no resemblance to the school of Giotto: it is inferior in design, yet equal in colouring. There are also two pictures by this master in the Academy at Venice. The celebrated Antonio Veneziano mentioned by Vasari executed some works in Venice about this time, but it is disputed whether he was a Venetian or a Florentine. There are a few other old painters of merit of this period whose names are known: Simon da Cusighe, Niccolo Friulano, and Pecino and Pietro de Nova.

In the 15th century a very different style prevailed; and although the artists of this period still designed with great stiffness and in the Gothic taste, they produced many admirably coloured pictures as regards the brilliancy and composition of colour, but in the local colours and reflexes they were yet deficient. The leaders of the improved style were some painters of the small island of Murano, and it has the glory of having been the nursery of the greatest painters of Venice. Titian studied at Murano. The first painters of this place were Quirico, Bernardino, and Andrea da Murano; but its great ornaments were the Vivarini. The oldest of this family is Luigi Vivarini the elder, by whom there is an excellent picture in its style of John the Baptist in the Venetian academy. The next in order of time of this family were Giovanni and Antonio Vivarini, according to Ridolfi and Zanetti, who lived about 1440. That there was a Giovanni Vivarini however is doubted by Lanzi. The only authority for mentioning him is the following inscription upon an altarpiece in San Pantaleone:—"Zuane e Antonio da Muran pense, 1444." But this Zuane is, according to Lanzi, the German known as Joannes de Alemania and Johan Alamanus, which is evident from the two following inscriptions:—"Joannes de Alemania et Antonius de Muriano pinxit," on a picture now in the Academy, formerly in the Scuola della Carità; and "Antonio de Muran e Zuhan Alamanus pinxit," on a painting at Padua. The remaining artists of this family were Bartolomeo, the brother of Antonio, and Luigi Vivarini the younger. In the Sala delle Antiche Pitture, in the Venetian Academy, there are several pictures by these masters: they differ little in style from the works of the Bellini. Bartolomeo was the first of the Venetians who painted in oil: his first oil picture is dated 1473; it is in the church of SS. Giovanni e Paolo. In the Scuola di San Girolamo there is an excellent picture of that saint with the lion, by Luigi Vivarini the younger. The principal contemporaries and rivals of the Vivarini in Venice were Jacopo Nerito of Padua and Nasocchio di Bassano the elder, both scholars of Gentile da Fabriano, who was employed in Venice in the beginning of the 15th century; also Jacopo Bellini, Francesco and his son Jacobello del Fiore, and a Morazone: also a Donato, and Carlo Crivelli, scholars of Jacobello. Jacobello attained great celebrity: there are works by him in different parts of the Venetian territory, bearing dates from 1401 to 1432. Donato was superior to his master in style. There was likewise a Vittorio Crivelli, who lived about the end of the 15th century.

Besides the painters already mentioned, there were others of equal merit in other parts of the state, in Bergamo and Brescia. In the former place a Commenduno; in the latter Brandolin Testorino and Ottaviano Brandino; also a Vincenzio Civerchino at Crema; Stefano da Zevio or Sebeto, a painter of great ability, and a Vincenzio di Stefano, his son, at Verona: the latter was the master of Liberale, who became the best painter of Verona of his time. At Verona, also in the latter part of the 15th century, was Vittore Pisanello, who executed many celebrated works in Venice and in Rome, but they have all perished; there are however yet a few of his works at Verona. From the accounts of Pisanello's works, they appear to have been of a very superior description, especially in design. He surpassed all his contemporaries in painting horses and other animals; he was also one of the most famous medalists of his time. Jacopo Tintorello and Marcello Figolino of Vicenza were likewise distinguished artists of this period; the latter painted in an original manner, and if the period assigned to him by Ridolfi be correct, 1450, he had a better knowledge of light and shade and perspective, and a greater delicacy of execution, than perhaps any of his contemporaries. The greatest master however of this period was Francesco Squarcione of Padua, who formed there the greatest school of painters ever brought together by one man: he had 137 scholars, and his museum of drawings and antiques was the richest known at that period. He had himself travelled over the whole of Italy and visited many parts of Greece for the express purpose of making a collection of drawings of the best remains of ancient art. He lived in great affluence, and divided many of his commissions among his scholars. The celebrated illustrated book of anthems in the church of the Misericordia, commonly ascribed to Mantegna, is now by competent judges considered one of the commissions of Squarcione executed by his numerous scholars. There is only one work at Padua known to have been done by Squarcione, painted for the Lazara family in 1452: it is excellent in colouring, in expression, and in perspective. Mantegna, Marco Zoppo, and Jacopo Bellini were scholars of Squarcione.

Trevigi also had its distinguished painters at this time: the following are mentioned by historians: Antonio, Liberale da Campo, and Giorgio da Trevigi: San Vito also had its Andrea Bellunello, who, as his countrymen thought, rivalled both Zeuxis and Apelles. Contemporary with him was Domenico di Tolmezzo.

Towards the end of the 15th century, about 1470, a great change took place in the Venetian method of colouring: the old methods of painting in distemper (*à tempera*), and with gums, &c, (*à guazzo*), were laid aside for what is now generally called oil-painting. This method was introduced into Venice by Antonello da Messina, who had learnt it in Flanders of John van Eyck. Roger of Bruges, likewise a scholar of Van Eyck, is said also to have visited Venice. The first Venetians who distinguished themselves in the new method were the Vivarini and the Bellini. Giovanni Bellini acquired the reputation of the most distinguished painter of his time in Venice: he painted from 1464 until 1516, and executed many works of various degrees of merit, highly finished, brilliantly coloured, but perhaps always in a dry manner; his figures however are frequently well drawn, and his expression was often excellent. Unlike most painters, he improved as he grew old, and condescended to borrow beauties from much younger masters: he endeavoured in his later works to imitate the design and colouring of Giorgione, his own pupil. His elder brother, Gentile Bellini, though very inferior to him, also acquired a great name. He was sent by the Venetian government to Constantinople to paint the portrait of Mahomet II. and other works. The Sultan had sent to Venice for a painter. The school of the Bellini, more particularly of Giovanni, was numerous and celebrated; but as, with the exception of Giorgione and Titian, their scholars painted in a style nearly identical with their masters, it will be sufficient here to mention the names of the principal: Bellin Bellini, Girolamo Mocetto, Nicolo Moretto, Marco Marziale, Giambattista Cima, Giovanni Martini, and Martino da Udine, or Pellegrino di San Daniello. There were others who painted in different styles and belong to other schools. Giovanni Bellini had two distinguished rivals, and perhaps superiors, in Vittore Carpuccio of Venice and Marco Basaiti of the Friuli: some of the works of the latter are the finest specimens of what may be termed the Gothic style that have ever been produced.

The painters of the Venetian states at the end of the 15th century, contemporary with the school of Bellini, were very numerous, and many of them painters of great merit, though more or less followers of the old style. The best were Carlos Cima, Vittore Beliiniano, and Jacopo Montagnana: others, who approached nearer to the new style, were Vincenzio Catena, Cordeglinghi, Francesco Bissolo, and Girolamo di Santa Croce.

As the school of Squarcione at Padua was opposed to that of the Bellini at Venice, and its numerous followers adopted a style distinct from that of the Venetian painters, which prevailed elsewhere throughout the state, it is unnecessary to mention them here: the best of them painted in the style of Mantegna, who established a distinct school at Mantua. Francesco da Ponte, a native of Vicenza, and the two Montagna and Bonconsigli, likewise of Vicenza, though born so near to Padua, were followers of the school of the Bellini. Francesco da Ponte was the founder of the Bassanese school: Bonconsigli, called Marescalco, was the best of all the painters of Vicenza of this period. In the Oratorio de' Turchini there is a Madonna on a throne surrounded by four saints by him, which is by some reckoned the finest picture in Vicenza. At Verona, at this time, the beginning of the 16th century, were Domenico Morone and his son Francesco, and also Girolamo da' Libri, who may be reckoned among the best masters of the old school; Girolamo da' Libri was the most celebrated miniature-painter of his time in Italy. Brescia at this period had also its distinguished painters, as Fioravante Ferramola and Paolo Zoppo; and Andrea Previtali, a scholar of Giovanni Bellini, acquired a great reputation at Bergamo. The art of inlaying with stained woods of different colours was practised with much skill at this time: the following artists are mentioned by Lanzi as having attained great distinction for this species of art:—Fra Giovanni da Verona, Fra Vincenzo dalle Vacche, Fra Raffaello da Brescia, Fra Damiano da Bergamo, Gian Francesco Capodiferro, and Bartolomeo da Pola.

Whilst the artists of the neighbouring cities of Venice were with more or less success contentedly following the dry manner of Bellini, it was completely exploded at Venice itself by two of his own scholars, Giorgio Barbarelli di Castelfranco, commonly called Giorgione, and Tiziano Vecellio da Cadore, or Titian. The former was born in 1477, and died in 1511; the latter, born in 1480, died in 1576. Giorgione introduced completely a new style of art: he discarded everything conventional, and worked upon the principle that the exact imitation of the effect of nature as a whole was the true object of a painter, whatever might be the nature or purpose of his representation: the difficulties of execution involved in the carrying out this principle, though a material one, are immense; the greatest of them, however, local colour and tone, are those which the painters of Venice appear to have most fully mastered. Mind has ever been less an object of study with the Venetian artists of this and the following periods, than the mere pictorial representation, which appears generally to have been the end of all their works: they painted for the picture's sake only, not for the lesson or moral that the picture might convey, a style properly designated the ornamental. Giorgione was the first to imitate the textures of stuffs: he painted all his draperies from the actual stuff represented, and painted draperies of many different substances. Before his time all draperies were made of the same material, and differed only in their colours or patterns. He is said to have been first led to the study of tone in light and shade from seeing the works of Lionardo da Vinci. His drawing was good, and his handling bold yet careful. Whether Giorgione, if he had lived longer, would have executed great works, in which every part and object would have been as perfectly executed as some of his single figures and their costumes, must remain a matter of opinion. This excellence was accomplished by Titian, and with a boldness of execution in his best works (in his earliest he finished highly) which far surpasses that of Giorgione; on which account, though originally an imitator of the style of Giorgione, he is deservedly accounted his superior, and is universally considered the founder of the great Venetian school of painting. Titian was in nothing ideal, but true in almost everything that he painted, if not in detail, at least in general effect. His scrupulous imitation of the effect of every object necessarily excluded the ideal from his works; and if his drawing is not the most chaste in style or correct in proportion, it is at least natural, and it is not so inferior that his other excellences do not compensate for its inferiority: in composition he was generally simple, but sometimes grand. In colour, local and absolute, he is allowed to have surpassed all other painters; in landscape, few have surpassed him; in portrait, few have equalled him. His principal masterpieces are considered—a St. Peter Martyr, in the church of Santi Giovanni e Paolo, and the Assumption of the Virgin, in the Academy at Venice; and the Martyrdom of San Lorenzo, at the Escurial in Spain, or at the church of the Jesuits at Venice: his numerous portraits, and Venuses, as they are called, are well known. [TITIAN, in BIOG. DIV.] The scholars of these two great painters were numerous. The following celebrated masters were among the scholars of Giorgione: Sebastiano del Piombo, Giovanni da Udine, Francesco Torbido, called Il Moro, Pietro Luzzo, called Larotto (and by Vasari, Morto da Feltro), and Lorenzo Luzzi. The scholars and imitators of Titian were likewise numerous, but the painters who might be strictly termed his scholars are very few. He is said to have instructed his brother Francesco Vecellio, who was an excellent painter, but Titian, through jealousy, according to report, persuaded him to turn merchant: his own son Orazio Vecellio was likewise a good painter, and there were still four other painters of this family: Marco Vecellio, the nephew of Titian; Tiziano Vecellio, the son of Marco, called Tizianello to distinguish him from Titian; also a Fabrizio and a Cesare Vecellio. Of his scholars, the principal were—Paris Bordone, a painter of the greatest ability; he was only a short time the scholar of Titian, and ultimately adopted a style of his own, though varying in nothing essential from that of Giorgione or Titian.

Two of Titian's most celebrated followers were Girolamo di Tiziano and Bonifazio of Verona, though called Veneziano by Vasari and others. To enumerate the followers of Titian, or Giorgione, or those who imitated the characteristics of their styles, would be to enumerate nearly all the painters of Venice of this period, besides many of those of the neighbouring cities. There are however yet a few names to be mentioned of painters contemporary with the two great leaders of this school, who, though they did not paint in their style, yet executed works which, in point of style of design, brilliancy of colour, and composition, are little inferior to theirs:—Lorenzo Lotto, Jacopo Palma the elder, Giovanni Cariani, and Girolamo da Trevigi, an excellent portrait-painter, who was killed in the service of Henry VIII. of England, at Boulogne in 1544. One of the most distinguished contemporaries of Titian also, and his chief rival in Venice, was Gian Antonio Licinio (born 1484, died 1540), commonly called Pordenone, from the place of his birth in the Friuli. He painted much in the style of Giorgione, but with still greater force of light and shade; and he was also one of the best of the Venetian fresco-painters. There were many in Venice who considered that Pordenone surpassed Titian: Zanetti, in speaking of these two rivals, says, in the style of Pordenone there is as much manner as nature, in that of Titian nature predominates. Pordenone formed a numerous school: Pomponio Amalteo was the most distinguished of his scholars, who himself also had many scholars, of whom Sebastiano Seccante was a distinguished painter. The following imitators of the style of Titian are all deserving of mention:—Andrea Schiavone di Sebenico, called Medula; Ludovico Fiumicelli, of Trevigi; Francesco Dominici, also of Trevigi; Gio. Battista Ponchino, of Castelfranco; Damiano Maza and Domenico Campagnola, of Padua; Giambattista Maganza, in Vicenza; Alessandro Bonvicino, called Il Moretto di Brescia (a painter of superior powers—he formed several good scholars); and Romanino Savoldo Gambara and Pietro Rosa, of Brescia—the first was the master of Girolamo Muziano, who afterwards distinguished himself at Rome; the second was known at Venice as Girolamo Bresciano. There were also many other painters of merit, of the school of Titian, in various other cities of the Venetian state; but the limits of this article will not admit of them all being enumerated by name.

It remains yet to mention three of the greatest ornaments of the golden age of Venetian painting, as this period is called—Jacopo Robusti, called Tintoretto; Jacopo da Ponte, called Bassano; and Paolo Cagliari, called Veronese. Tintoretto (born 1512, died 1494), so named from the trade of his father, a dyer, is generally called the pupil of Titian, but he remained only twelve days with him, and this at a time when he was very young. [TINTORETTO, in BIOG. DIV.] He professed to colour like Titian, and to draw like Michel Angelo; his practice however did not accord with his profession, for compared with Titian, he was cold in colouring, and extremely heavy in light and shade; he was fond of violent contrasts and great masses of light and shade; in design, though muscular, he was often lean and incorrect; and in his compositions he was fond of many figures, generally thrown together without arrangement. He was however extremely unequal in his works, some of which are amongst the finest productions of the Venetian school; his masterpiece is generally considered the Miracolo dello Schiavo, in the Academy at Venice: he put his name to this picture and to the two following—the Crucifixion, at San Rocco, and the Marriage at Cana, in the Church of Santa Maria della Salute. Many of Tintoretto's greatest pictures are merely dead-coloured, and that in a most careless manner: he was extraordinarily rapid in his execution,—he acquired the name of Il Furioso in consequence: Sebastian del Piombo said that Tintoretto could do as much in two days as he could do in two years. Bassano (born 1510, died 1592) commenced as an historical painter in the grand style, and as an imitator of Titian; but after he left Venice he changed it for an original style of his own in the characteristic style of the Dutch painters, and he was the first to introduce the taste for such works into Italy. He painted landscapes, animals, domestic scenes, kitchens, &c., and the various utensils for drinking, &c., particularly of brass. In the church of Santa Maria Maggiore at Venice is a Sacrifice of Noah, in which he introduced all the birds and animals that he had drawn elsewhere: his greatest excellence was his colouring. He brought up four sons as painters, but they were inferior to their father. Paolo Veronese (born 1528, died 1588), though in his principles of colouring identical with the other great masters of Venice, from the splendour of his great compositions may be said to have formed a new style of his own. He was fond of crowds of people, arrayed with all the pomp and splendour that the imagination and colour could accomplish, filling his backgrounds with piles of the richest architecture. He was however, as Algarotti says, careless in design, and in costume extremely licentious; but his fancy was noble, his invention inexhaustible, and even his faults are pleasing: one can scarcely look at his magnificent pictures without longing to be a party in the scene. One of his grandest compositions is the Marriage at Cana, in the Louvre—a vast composition, more than 20 feet high, and upwards of 30 wide: it contains about 150 heads, many of which are portraits of the most illustrious and distinguished persons of his time. Another of his chief works, 'the Family of Darius,' is in the National Gallery. Paolo Veronese was the real master of Rubens. Verona had at this time three other painters little inferior to Paolo himself: Battista d'Angelo, called Del Moro, scholar and son-in-law of Torbido; Domenico Ricci, called Brusasorci; and Paolo Farinato, called degli Uberti.

Of the assistants and scholars of Paolo the most distinguished were his brother Benedetto Cagliari, who generally painted his architecture for him; his son Carlo Cagliari, called Carletto, who died young; Gabriele Cagliari, likewise his son; and Battista Zelotti, the most distinguished of all his followers.

After the time of the great masters just spoken of, in the 17th century the Venetian school of painting declined as much and as rapidly as the Florentine did after the time of Michel Angelo. Many of the Venetians of this period, mistaking apparently brilliancy for art, cultivated little besides colour, and many of their pictures are mere compositions of silks, satins, and other stuffs. There were however several good painters during this period of decline. Jacopo Palma the younger (born 1544, died about 1628) holds a middle place between the great painters of the last period and the mannerists of this. Lanzi calls him the last of the good age and the first of the bad. He painted somewhat between the styles of Tintoretto and Paul Veronese; had many defects and many beauties, and produced many bad and several admirable pictures. Marco

Boschini, painter and engraver, was a scholar of Palma; he is known for an esteemed work on painting, principally on the style and works of the Venetian painters of his own and former times, entitled "La Carta del Navegar Pittoresco." The following painters were the principal contemporaries of Palma, who painted somewhat in his style: — Leonardo Corona, Andrea Vicentino, Santo Peranda, Antonio Vassilacchi, called L'Aliense: Pietro Malombra, and Girolamo Pilotto. Giuseppe Porta, called Salviati, Matteo Ponzone, the scholar of Peranda and Pietro Damini scholar of Gio. Battista Novelli, were likewise three of the best painters of this time.

In 1630 and 1631 many painters were carried off by the plague, which visited Venice in those years; and traces of the excellences of the great masters were after that time still more rare in the works of the surviving painters of Venice. In the middle of the 17th century the style of M. A. Caravaggio and the Naturalisti began to prevail there, and several foreigners supplanted the Venetian painters in public estimation in Venice itself. The followers of Caravaggio in Venice were on account of their dark shadows, called by the Venetian painters the Tenebrosi: the pictures of the masters of this school are dark from two causes—from their style of colouring and from their practice of painting upon dark grounds, upon which the middle tints never stand. The pictures painted on such grounds darken after a time, and high lights and deep shadows are all that appear. Of these Naturalisti and Tenebrosi, Pietro Ricchi of Lucca, called Il Lucchese, was one of the best; others were Carlo Saraceni, Francesco Rusca, Stefano Pauluzzi, Matteo da' Pitocchi, and Bastiano Mazzoni. Of strangers distinguished in other styles the following were the most successful:—Antonio Triva of Reggio, a scholar of Guercino; Bernardo Strozza, his scholar Langetti, and Niccolo Cassana, of Genoa; Antonio Bavarense, of Bavaria; and Federigo Cervelli, of Milan, the master of Sebastiano Ricci. The painters of this period who still followed the style of the great leader of the Venetian school were Giovanni Contarino and his scholar Tiberio Tinelli, celebrated portrait painters; also Girolamo Forabosco, Pietro Bellotti, and Carlo Ridolfi, well known for his Lives of the Venetian painters, 'Le Maraviglie dell' Arte, ovvero le Vite degli illustri Pittori Veneti e dello Stato,' 2 vols. 4to., Venice, 1648, which is one of the best of the Italian works of this kind. Ridolfi was a native of Verona, where, of all the cities of the Venetian state, what is more properly the Venetian style still prevailed with least deterioration. Dario Varotari, the father of Alessandro, called Padovanino, Alessandro Turchi, called L'Orbetto, and Pasquale Ottini, all amongst the best painters of their time, were natives of Verona.

Padovanino (born at Padua, 1590, died 1650) went young to Venice to study the works of Titian, and became the most distinguished painter of this school of the 17th century, and is one of the best of Titian's imitators: his masterpiece is the Marriage at Cana, in the Academy at Venice. Scaligero, his principal scholar, also acquired reputation.

Another great painter of Padua of this time was Pietro Liberi, sometimes called Libertino, from the character of his naked Venuses, of which he painted many. At Vicenza the beauties of this school were still preserved to a considerable degree by Alessandro Maganza, an imitator of Paul Veronese and Zelotti; Francesco Maffei, scholar of Peranda; Giulio Carpioni, scholar of Padovanino; and Bartolomeo Cittadella, the scholar of Carpioni.

At the end of the 17th century no particular style prevailed in Venice, and all the various classes of painting had their votaries: landscape, architecture, battle, and marine painters were alike numerous. Zanetti states that there were as many styles as painters in Venice at the end of the 17th century. In historical painting however the works of the Bolognese painters as in almost every other city at that time, were likewise in Venice the chief objects of attraction. Still, says Lanzi, the old masters were not on this account underrated, but were spoken of as the ancients of a golden age, whose customs were to be praised, but not imitated. The colouring of the painters of this period in Venice was more brilliant than that of the great masters, but what they gained in brilliancy they lost in truth: in drawing, however, and in costume some of these painters had the advantage of their predecessors, but in these respects the Venetians were never very distinguished. Of these painters the following may be mentioned: Andrea Celesti, who painted sometimes in the style of Caravaggio, but more generally in the style of Paul Veronese than of any other master; and Antonio Zanchi of Este, better known for the number than esteemed for the merit of his works, painted likewise sometimes in the style of Caravaggio and sometimes in that of Tintoretto. In the Scuola di San Rocco there is a celebrated picture by him of the Plague of Venice in 1630, and opposite to it in that place there is a picture of the Liberation from the Plague, by his scholar Pietro Negri. Francesco Trevisani was also one of his scholars, but he settled early in Rome. To these may be added the names of Antonio Molinari, Antonio Belluci, Giovanni Segala, Gio. Antonio Fumiani, and Niccolo Bambini. The last was the scholar of Carlo Maratta in Rome, and many of his pictures are painted entirely in the Roman style. But a more distinguished painter and a better draughtsman than any of these was Gregorio Lazzarini, who painted in the style of the best Bolognese and Roman painters of the period, though he never left Venice. Antonio Pellegrini acquired a name in various countries of Europe. Jacopo Amigoni also attained great celebrity, less in Venice, however, than in England, in Germany, and in Spain; his pictures are extremely bright and brilliant. Other distinguished painters of this age entitled to be mentioned were Giambattista Pittoni and Giambattista Piazetta: the former was celebrated for his powerful effects of light and shade in the manner of Guercino, but through a bad method of colouring, his pictures in a short time lost all their beauty in this respect; his execution was rapid and careless. He was a good caricaturist, and he was remarkably popular in his time. One of the scholars of Piazetta, Giambattista Tiepolo, was the last of the Venetians who acquired a great name. He was one of the best painters of the 18th century, and acquired a great reputation in Italy, in Germany, and in Spain, where he died at Madrid about 1770. He excelled chiefly in fresco, and he painted more in the style of Paul Veronese than that of Piazetta. [TIEPOLO, in BIOG. DIV.] He had a distinguished scholar in Fabio Canale. Although Tiepolo may be termed the last of the great Venetian painters, there were still several perhaps of equal ability in the state. Before mentioning these however, we have yet to notice one of the greatest painters of the 18th century, who, though not a Venetian, was first educated at Venice by Cervelli, Sebastiano Ricci, or Rizzi, born at Cividal di Belluno in 1660, and died in 1734. He travelled over Italy, and visited Germany, England, and Flanders, and earned the reputation of a great painter wherever he went. He had a great facility in imitating the styles of other masters: he painted in fresco and in oil. His colouring was rich and agreeable, though he occasionally introduced too much azure in his draperies. His composition and design were graceful; in design he was better than the Venetians: his handling was free and yet not careless. His nephew Marco Ricci was a distinguished landscape painter. Ricci had several scholars: the most distinguished were Gaspero Daziani and Francesco Fontebasso.

It remains now only to mention the distinguished painters of the Venetian state, in the 18th century, not already noticed. Antonio Zifrondi of Bergamo, a painter of remarkable facility of execution; and of the same place, Fra Vittore Ghirlandi and Bartolomeo Nazzari, were both excellent portrait painters. In Brescia, Avogadro Bresciano was distinguished for rich colour, elegant composition, and good drawing; likewise Andrea Toresani, but he practised more in Venice and Milan than in Brescia: he was distinguished for landscapes and marine pieces, which he embellished with figures and animals painted in excellent taste. Simone Brentana, though a native of Venice, was domiciliated at Verona, and painted many excellent works there. Of Verona also was Antonio Balestra, who studied at Venice, at Bologna, and at Rome with Carlo Maratta: he painted less in the Venetian taste than in the Bolognese and Roman; he drew well, composed with judgment, and executed many excellent works: Gio. Battista Mariotti, Giuseppe Nogari, and Pietro Longhi, Venetians, were his scholars. The first was a good imitator of his style; the second excelled as a portrait painter, but painted also some historical pieces; the third was distinguished for masks, conversations, and landscapes. Carlo Salis of Verona, and Cavalcabo of Roveredo, both painters of great merit, were likewise the scholars of Balestra; and also another Veronese painter, one of the best of the 18th century, Il Conte Pietro Rotari: he excelled in every department of painting except colouring, yet in this respect he was harmonious; his colouring was ashy and melancholy; he died at St. Petersburg in 1762, painter to the empress Catherine II. of Russia. The last of the distinguished painters of Verona was Gio. Bettino Cignaroli, likewise instructed by Balestra: he drew also in the style of Maratta; his masterpiece is perhaps the Flight into Egypt, at St. Antonio Abate at Parma: he died in 1770. The emperor Joseph II. is reported to have said, that he had beheld two very rare things in Verona—the amphitheatre, and the first painter of Europe.

Santo Prunati of Verona, contemporary with Balestra at Verona, was also a good painter; and there was a Pietro Uberti at Venice, an excellent portrait painter. A very distinguished painter also of this period at Venice, though of a different class, was Antonio Canaletto, known throughout Europe for his views in Venice, and other cities in and out of Italy.

Roman School. That style of art which was eventually formed, or prevailed, at Rome during the golden age of painting, in the beginning of the 16th century, is termed the Roman school, whether it was practised by subjects of the papal government, natives of the city of Rome, or strangers resident there. The simple fact however, of having practised the art of painting in Rome, does not constitute a disciple of that school. The works of Raffaelle exhibit this style in its full development or most perfect form, and he is accordingly the head or representative of the Roman school.

In retracing the progress of the Roman school, we must go back to that original school of Italian painting, which flourished in the 14th century in various cities of the Roman states, within the limits of ancient Umbria,—in Gubbio, Fabriano, Maselica, Borgo S. Sepolcro, Urbino, Assisi, and other places,—and thence termed the Umbrian school.

Oderigi of Gubbio, one of the old practitioners of missal-painting, an art which was never quite extinct in Italy, seems to be the most ancient painter of this school whose period is ascertained with any degree of certainty; he died about A.D. 1300. Oderigi appears to have been an active reviver of painting, and he was a man of reputation in his day. He is mentioned honourably by Dante, who terms him "L'onor d' Agobbio, e l'onor di quell' arte."

There is mention also of three other ancient painters of Gubbio: Cecco and Puccio, who were employed in 1321 in painting the dome of Orvieto; and Guido Palmerucci, who was employed about 1324, in the town-hall of his native city.

A still more important name in the early history of the Roman school is that of Pietro Cavallini, who is said to have received instruction from Giotto while at Rome. A Crucifixion by this master, still extant at Assisi, is a remarkable production. The return of the papal government from Avignon to Rome gave a new impulse to the arts; the most skilful artists were sought throughout Italy to decorate the temples and palaces of the luxurious pontiffs of Rome. Of these the principal were Ottaviano Martis, and Gentile da Fabriano, a master of much greater merits. Fabriano was surnamed Magister Magistrorum, and practised his art in many parts of Italy. In 1417 we find him engaged at Orvieto; he resided afterwards at Venice, where he obtained the rank of patrician, and was the master of Giacopo Bellini, whose sons were the founders of the Venetian school. His style, which by Michel Angelo was pronounced to be, like his name, "Gentile," somewhat resembled that of Fra Angelico da Fiesole, though it was much inferior to it.

Piero della Francesca, or Piero Borghese, advanced the art still further; he was reckoned one of the best geometricians of his time, and was the first Italian who had any knowledge of the principles of perspective. He introduced immense improvements in the management of draperies, and also greatly enlarged the manner of treating the naked figure. Bramante studied the works of Piero, who was fond of introducing architectural backgrounds in his pictures, which he executed in tolerable perspective. Additional improvements were made by Bartolomeo Corradini of Urbino, called Fra Carnevale, who gave great character to his heads, and was the first to introduce portraits into historical compositions, in which practice he was afterwards followed by Raffaelle, who paid great attention to the works of this painter at the commencement of his career.

Niccolo Alunno of Foligno and Benedetto Bonfigli complete the list of the considerable artists of this school previous to and contemporary with Pietro Perugino, the master of Raffaelle, and Giovanni Sanzio of Urbino, his father. Although, through the united efforts of the above masters, painting had attained to many high and pleasing qualities, true taste in design may be said to have totally failed them. They had not yet discovered what was beautiful and what was not, or what belonged to the individual and what to the class. Their art was not truly imitative, nor does it seem that an appearance of reality was an object with these painters; they seem to have considered that their end was sufficiently accomplished in an intelligible indication of whatever they represented. The deficiency of this school could only be supplied through the study of the antique, and to supply it in a great degree was a distinction which fell to the lot of Masaccio, who must be looked upon as the leader of the great painters of the 15th century, or the Quatrocentisti, as the Italians have termed them, among whose works we first perceive any distinctive characteristics of style.

It cannot be denied that Perugino owed his great superiority over his predecessors to his visit to Florence, where, whether he became the pupil of Verocchio or not, which is a matter of dispute, he was at least enabled to study the noble works of Masaccio. His taste was however still dry and mean, his design was meagre and feeble, though often correct, his draperies were stiff and in a little manner, yet his colouring was sometimes exceedingly rich, and for graceful delicacy of attitude and motion, and a softness and simplicity of expression, he surpassed all his contemporaries. But there is a symmetrical repetition and similarity in the disposition of his figures, which betray a total absence of anything like vigour or truth of composition, and which place him at an immeasurable distance from his great scholar. No pupils ever imitated their master so closely as, with the exception of Raffaelle, did those of Perugino; and many of their works are reputed works of their master. His most celebrated scholars were, Bernardino Pinturicchio; Andrew Luigi of Assisi, called L'Ingegno on account of his great abilities, who became blind when still young; Domenico and his son Orazio di Paris Alfani; Eusebio da S. Giorgio; Giannicola da Perugia; Lo Spagna; Berto di Giovanni; Sinibaldo da Perugia; Adone Doni of Assisi; and Palmerini of Urbino. The works of all these masters were more or less conspicuous for symmetrical composition and a profuse application of gold.

We now arrive at the pride of Perugino and the glory of the Roman School, Raffaello Sanzio d'Urbino, the first of painters; for moral force in allegory and history, unrivalled; for fidelity in portrait, unsurpassed; who has never been approached in propriety of invention, composition, or expression; who is almost without a rival in design; and in sublimity and grandeur, inferior to Michel Angelo alone, whose prophets and sibyls in the Capella Sistina are in these respects unquestionably the triumphs of modern art.

It must not be supposed that Raffaelle attained these great qualities intuitively: they were the result of long and intense application; and in the works of no artist is the progress of improvement so apparent as in those of Raffaelle. He painted in three styles: his first was that of Perugino. His second was an enlargement of that style in the taste of Fra Bartolomeo, and is termed his Florentine; but this change or improvement in style was not effected through an acquaintance with that great painter alone, but also through the impression made upon Raffaelle's mind by the works of Masaccio, of Lionardo da Vinci, and also of Michel Angelo, at Florence. His third style, which is the subject we have now more particularly to consider, was peculiarly his own; although those magnificent works the Prophets and Sibyls of Michel Angelo were the principal causes of its ultimate fulness and grandeur. This third style, which is the proper style of Raffaelle, constitutes the Roman school in its full development, which is the least defective of all the schools of painting.

There is a degree to which the powers of imitation may be combined with those of the imagination, which, when regulated by a just refinement of feeling or taste, constitutes the perfection of painting, and this degree, though not attained, was in the aggregate approximated more nearly by Raffaelle than by any other painter. He never designed a figure which he did not inspire with appropriate sentiment; the affections of mankind were the sphere of his genius; from the calculating sage to the thoughtless infant, his works are the history of the human heart, and deservedly has he been entitled the "painter of the passions." The elements of his style are nowhere more apparent than in the Cartoons at Hampton Court. To particularise amidst so much excellence, and to single out the works in which Raffaelle has been most eminently successful, is rather a delicate task; yet perhaps the following examples may be instanced as being more decidedly conspicuous for those particular qualities which characterise his style:—for grandeur of design, the Heliodorus; for sublimity of character and conception, the Madonna di San Sisto; for composition and expression, the Cartoons; and perhaps for invention and general technical excellence, the Transfiguration, his last performance. [RAFFAELLE, in BIOG. DIV.]

The style of Raffaelle has seldom been found congenial to their taste by the lovers of colour, and certainly those who consider the perfection of painting to consist in splendid colouring must not look for it in the works of the Roman school, but in those of Paul Veronese or of Rubens. Many critics have regretted that Raffaelle did not colour like Titian; but colour was to Raffaelle a *means*, and not an *end*, as it was with the majority of the Venetian painters; and its effect is to dazzle and to obscure, rather than to enhance the essential qualities of the grand style. For as the painted face of a player harmonises with the accompanying spectacle and the tone of light around, and would as certainly be ridiculous if exposed to the light of day, so the Venetian colouring, which is in such perfect harmony with the subjects of that school and their general treatment, would as certainly be in discordance with those qualities which characterise the style of Raffaelle. Even Ludovico Caracci, the founder of the Eclectic school of Bologna, discovered that Venetian colouring was inapplicable to the subjects which he chose for his own pencil. And Raffaelle would not have been the great painter that he proved himself to be, had he chosen any other than the sombre colour for which he is so conspicuous, and which, so far from being a defect in his style, is indeed an additional evidence of his profound genius. These remarks do not refer to the carnations particularly, which should always harmonise with the draperies, but to the composition of colours generally, to their choice and intensity, and also to the stuffs and materials of which the draperies are composed. Raffaelle rarely if ever painted silks or satins; most of the Venetians seldom painted anything else.

Raffaelle had many scholars and many imitators; of the former, the principal were Giulio Romano, Gianfrancesco Penni (with Giulio, Raffaelle's principal heir), and Perino del Vaga: these painters completed, from Raffaelle's designs, the great works in the Vatican, which he had left unfinished.

Giulio Pippi, called Giulio Romano, certainly the most eminent of all Raffaelle's scholars and imitators, was conspicuous for the correct and powerful design of his master, but in other respects he never approached him. Although he had great powers of invention, an unpleasing expression and an evident absence of sentiment prevail throughout his works. He is also heavy both in design and colouring; but his particular employment under Raffaelle, that of dead-colouring and preparing his works in oil, may have greatly contributed to this effect. Giulio left Rome during the pontificate of Clement VII., shortly after the completion of the Constantine series in the Vatican, and, at the invitation of Federigo Gonzaga, repaired to Mantua, where he founded a school and painted his famous works, the Fall of the Giants, and the Loves of Cupid and Psyche. [GIULIO ROMANO, in BIOG. DIV.]

Gianfrancesco Penni, with little less vigour than Giulio, was conspicuous for more of the grace of his master. Pierino Buonaccorsi, called Perino del Vaga, displayed nearly equal powers. Other pupils and assistants of Raffaelle in the stanze and the loggie of the Vatican, were—Giovanni da Udine; Polidoro Caldara da Caravaggio, celebrated for his imitations of ancient bassi rilievi; Pellegrino da Modena; Bartolomeo Ramenghi, called Il Bagnacavallo; Vincenzio di S. Gimignano; Timoteo della Vite; Raffaellino del Colle; Benvenuto Tisi, called Il Garofolo; and many others too numerous to mention here.

The accession of Adrian VI. to the papal chair had for a time paralysed the arts, but they were shortly inspired with new vigour by his successor Clement VII., Guilian de' Medici, who continued the works that had been interrupted by Adrian. But a more serious interruption succeeded in the sack of Rome, in 1527, by the soldiers of

Bourbon. The vast school of painters formed by Raffaelle was totally dispersed: it spread however the elements of his style all over Italy, although scarcely a single beauty of the original was to any extent preserved in the copies.

In the pontificate of Paul III., the arts commenced again to revive in Rome. Michel Angelo executed his great work of the Last Judgment, the labour of eight years, by the orders of this pontiff: it was completed in 1541. The effect however of this work was for a time fatal to painting; hosts of copyists and mannerists arose, who, possessed with a mania for representing the naked figure, and sacrificing everything to anatomical display, imagined the perfection of design to consist in violent action and muscular protuberance; and in imitating the manner, they imagined they had acquired the *art* of Michel Angelo.

This great painter, who in the time of Julius II. had himself been chiefly instrumental in raising painting nearer to perfection than it has ever attained in modern times, lived also to see it degenerate, greatly through his own influence, into a mere handicraft in the time of Pius IV., when a reference to nature was considered as an acknowlegment of a want of genius.

The most distinguished mannerists of this school and period, whose style was a species of compound of those of Raffaelle and Michel Angelo, without the correctness or purity of the former, and with only the manner of the latter, were Taddeo and Federigo Zuccari. The former died young. The latter executed vast works at Florence, which were, however, remarkable for their vastness alone; and he has left specimens of his pencil in the principal cities of Italy. He succeeded Girolamo Muziano as president of the Academy of St. Luke at Rome, which had been lately founded by Gregory XIII. at the instance of Muziano. Gregory was elected in 1572.

The following exceptions should be mentioned, as being distinguished for their greater propriety of style, from the general host of mannerists:—Girolamo Siciolante of Sermoneta, Marcello Venusti, and Livio Agresti, all scholars of Perino del Vaga; also Scipione Pulzone, called Gaetano, the scholar of Giacopo del Conte, both excellent in portrait.

Guiseppe Cesari d' Arpino succeeded Federigo Zuccaro in public estimation at Rome; but though without a rival in that city until the appearance of Michel Angelo Amerighi, Il Caravaggio, he cannot be said to belong to the Roman school. The heavy and vulgar nature of Caravaggio's style was in direct opposition to the ideal mannerism of Cesari's. They both had their partisans, who were termed respectively naturalisti and idealisti; the latter prevailed. Annibale Caracci also endeavoured in vain to reform taste in Rome: the works of this great master in the Palazzo Farnese had little or no effect upon the style of the Roman painters of the period, and Cesari left a numerous school of imitators. But these noble works, certainly inferior only to those of Michel Angelo and Raffaelle in Rome, eventually had their effect, and painting was again restored to something approaching its former splendour; and what the painters of Bologna had borrowed from the Romans in the pontificate of Clement VII., the pupils of the Caracci returned with interest in that of Urban VIII.

A better style was adopted by Federigo Baroccio of Urbino, which might boast of a nearer approach to the correctness of form of the great founder of the Roman school; but his colouring was generally artificial, and very different from that of Raffaelle. Its tone is unpleasant, a cold violet hue prevails throughout, and there is a striking deficiency of yellow in his carnations, which in the lights are pink, in the shadows gray. Baroccio had several imitators, but his influence upon the general character of Roman art was inconsiderable. The Eclectic school of Bologna seems to have had the principal share in reforming the art in Rome. During the pontificates of Paul V., Gregory XV., and Urban VIII., the celebrated pupils of the Caracci, Domenichino, Guido, Guercino, and Lanfranco, were much employed by those pontiffs; and the example of these great masters, but more especially of Domenichino, produced many good painters, of whom we may mention the following:—Antonio Ricci (called Barbalunga), Camassei, Giovanni Carbone, Francesco Cozza, Pietro del Po, Canini, Giambatista Passeri, and Luigi Scaramuccia, and there were many others of considerable merit. The school of the Caracci seems to have had a more immediate influence upon portrait-painting, truth or fidelity of representation being indispensably requisite to constitute excellence in portraiture. The excessive mannerism of the painters of the period had so generally incapacitated them for executing anything excellent in that department, that it began to be nearly a distinct profession, and the following masters distinguished themselves as excellent portrait-painters, though they did not confine themselves quite exclusively to portraits:—Antonio di Monti, Pietro Fachetti, Antonio Scalvati, Grammatica, Ottavio Leoni, and Baldassare Alloisi, called Galanino.

Upon the imitators of Domenichino followed the bold style of Lanfranco, whose most successful scholar was Giacinto Brandi; and contemporary with Lanfranco flourished Albano in Rome. Pier Francesco Mola was an imitator of his style.

From the studio of Albano came Andrea Sacchi, a painter who drew well and coloured admirably, who never bestowed labour upon a trifle, and who was better versed in the theory of art than any of his contemporaries or immediate predecessors. There is a grandeur about his style, and a truth and breadth in his execution, which distinguish him as one of the noblest disciples of the Roman school, second only to Giulio Romano in invention, and in all other respects inferior to its great founder alone. Raffaello was his model of perfection; but he was no servile imitator: he could appreciate also the beauties of Titian and of Correggio; and he had recourse to the same sources through which his great model attained to excellence—nature and the antique, but he availed himself only so far of the antique as it served to regulate his study of nature.

No inconsiderable ornament also of the arts of Rome of this period was Nicholas Poussin, for though a Frenchman by birth, he was essentially a Roman painter. He formed his style from Raffaelle and the antique. He attended also the academies of Domenichino and of Sacchi, being a great admirer of the works of those masters. His style was however very peculiar, and had no influence upon the arts in Rome; his works have too much the appearance of painted bassirilievi.

Pietro Berrettini, called also Pietro da Cortona, set himself up as the rival of Sacchi in Rome; and if the number of imitators is a criterion of the degree of excellence, Pietro da Cortona was certainly superior to Sacchi. The art of Sacchi was not so easily imitated. The style of Cortona was rich and attractive, but superficial and incorrect, and he takes the lead in that class of painters termed machinists by the Italians.

The scholars of these two masters formed two rival factions of art, which divided Rome: that of Sacchi was headed by Carlo Maratta, supported by Ludovico Garzi; that of Cortona by Ciro Ferri, supported by Romanelli. Bernini, who, during the pontificates of Urban VIII. and Innocent X., in matters of art was all-powerful in Rome, opposed, as was to be expected, that party which was conspicuous for good taste; and for a time the machinists prevailed. But the school of Cortona was predominant only in fresco, for in oil Maratta was unrivalled. In 1689, however, Ciro died, and Maratta stood alone; and upon the accession of Innocent XII., in 1691, he was appointed inspector of the stanze of the Vatican, and in 1702, by the orders of Clement XI., he restored the works of Raffaelle in those apartments, which had considerably suffered through time and neglect. He had restored previously the frescoes of Annibale Caracci in the Palazzo Farnese. He died in 1713. His style was generally considerably less vigorous than that of Sacchi, and both his colouring and his composition were occasionally artificial; his drawing was also sometimes incorrect; and his taste was upon the whole very inferior to his master's, though his style has been termed more graceful.

Maratta formed a most numerous school, but its chief characteristics were the studied composition and affected grace which are the blemishes of his own style.

Maratta has been termed the last of the Romans, and perhaps he may be safely termed the last of the Romans who has merited the name of a great painter; for neither Pompeo Batoni nor Mengs can be said to dispute that claim with him, though both are deservedly celebrated names. The former gave too much importance to high finish; the latter was too blindly devoted to the antique. Batoni painted excellent portraits, and Mengs drew correctly, but he was so eager after the ideal that he lost nature in the search of it; in this respect Batoni has greatly the advantage over Mengs. They were both eminently academic, and for mere technical excellence have not often been equalled; but there is a palpable absence of the "mens divinior" and moral sentiment in their works, which are more than ordinarily conspicuous for that insipidity and monotony so generally attendant upon the fastidious preciseness of academic art.

The Bolognese School divides with the schools of Tuscany, Rome, and Venice, the honour of having assisted in bringing about the great revival of painting in Italy in the 13th century. But unlike them its advance was slow; it had no great painter to share in the glory of that brilliant epoch, the beginning of the 16th century, when the greatest masters of Italian painting flourished contemporaneously. Its culminating point was reached much later, and then hardly as the result of original genius. The school of Bologna is chiefly remembered as an eclectic school. Its heads, the Caracci, sought to achieve the highest excellence by imitating and combining the peculiar excellencies of the great masters of other schools: and in the opinion of their contemporaries they succeeded. Not only by their countrymen, but by the painters of other schools their principles were adopted; and their influence thus extending throughout Italy, and coinciding with the tendencies of the age, served to repress what little originality remained and to produce everywhere a uniformity of academic mediocrity. This school is therefore historically one of the most important in modern art, but we need not speak further of it here, having already treated of it under BOLOGNESE SCHOOL OF PAINTING.

Of other Italian schools our notice must necessarily be very brief. Chief of these are the *Schools of Lombardy*, which however are so broken up and subdivided, almost every city claiming a school of its own, that even if our space permitted, it would be tedious to retrace so often the same ground as would be necessary in speaking of them however cursorily. Lanzi has given the history at length of no less than five Lombard schools; those namely of Mantua, Modena, Parma, Cremona, and Milan. Of these the most famous, as having produced Correggio and so imparted a distinct character to Lombard painting, is that of Parma. But Andrea Mantegna, a native of Padua (born

1431, died 1506) must be considered as the true founder of Lombard painting, he having settled in Mantua and established there the school whence proceeded many of the chief painters who have adorned the schools of Lombardy. Mantegna's most famous paintings are his 'Virgin and Saints,' and 'Victory,' both in Mantua, but what Vasari and his contemporaries regarded as his masterpiece, the series of designs in water-colours, entitled 'The Triumph of Julius Cæsar,' is now in Hampton Court Palace. The great influence of Lionardo da Vinci on the schools of Lombardy has been already noticed in speaking of the Tuscan school.

Antonio Allegri, or, from his birth-place, Correggio (b. 1494, d. 1534), may have been instructed in the school of Mantegna, though after the death of Andrea, but he probably learnt more from the works of Lionardo da Vinci in Milan, and from the practice of that master's scholars; and he appears to have studied the paintings of Giorgione and Titian. Nothing in the history of art seems so *premature* as the style of Correggio. His early pictures at Dresden show the same colouring which he afterwards carried to such perfection. His feeling for grace, tenderness, and delicacy of expression led him sometimes to the verge of sentimentalism; but nothing can be purer or more refined in feeling than some of his best works. Of colour and chiaroscuro his mastery was perfect. No other artist ever played with light and shadow as he was wont to do. His half tones and his reflected lights produce the effect of illusion. He knew his power, and delighted in displaying it in the conquest of difficulties from which other masters shrank. The finest works of Correggio are the frescoes in the cathedral of Parma, and in the convent of St. Paul, in that city, the Notte and other pictures at Dresden. In the National Gallery are some very fine easel pictures by him, especially the 'Ecce Homo,' 'Venus instructing Cupid,' and the 'Vierge au Panier.' [Correggio, in Biog. Div.] The tendency to affectation visible in Correggio was a dangerous legacy to the school of Parma, and its evil consequences are especially visible in the works of Francesco Mazzola, or Il Parmigiano (b. 1503, d. 1540), to whom however it is impossible to deny great power and great feeling for beauty. [Parmigiano, in Biog. Div.] But the influence of Correggio was not lasting in the schools of Lombardy. Like those of the rest of Italy they became imbued with the principles of the Caracci, and the later painters of Lombardy are feebly eclectic or coldly academic.

Of the *Neapolitan school* the earliest painter was Tommaso de' Stefani, a contemporary of Cimabue; and it can trace the succession down to the present day; but among them are very few great names. Of the 15th century the chief is Antonio Solario, called Lo Zingaro, a scholar of Lippo Dalmasio of Bologna, but who also studied under Gentile da Fabriano at Rome, and indeed in most of the cities of Italy, and whose numerous scholars formed what is called the school of Zingaro. His most celebrated work was a fresco in the choir of S. Severino, which represented in several compartments the principal events in the life of S. Benedict, and which, according to Lanzi, contained an incredible variety of figures. Antonello da Messina is also claimed by the Neapolitans; but from having practised his art at Venice until his death is usually placed among Venetian painters. Andrea Sabbatini da Salerno, whose style was formed on that of the Roman painters, and especially of Perugino and Raffaelle, is the greatest name of the 16th century. Of the 17th century the great masters are Giuseppe Ribera, called Lo Spagnoletto (b. 1592, d. 1656)—claimed by the Neapolitans from having practised in Naples, though a Spaniard by birth, and Salvator Rosa (b. 1615, d. 1673). Both of these painters owed much of their daring exaggeration and coarseness of style to the example of Caravaggio, the founder of the so-called 'Naturalisti.' The Spaniard had considerable native vigour, and he shrank from the representation of no scene however horrible. His best pictures are in Naples, and among them are a 'Martyrdom of S. Januarius,' in the Royal Chapel, and a S. Jerome in the church of the Trinity. Several of his pictures are in Spain, and among them are 'Ixion on the Wheel,' in the palace of the Buon Retiro, at Madrid. Salvator Rosa possessed more varied powers; but he was a man of irregular life, and something of his character is reflected in his works. His landscapes (often wild scenes in the Apennines) and his battle-pieces are the most prized of his productions, and are superior to his historical pictures.

Salvator had many followers, but, as in the other schools, the Neapolitan painters fell in due course under the influence of the dominant eclecticism, and ceased to have any distinctive character. The last Neapolitan painter who requires mention is Luca Giordano, called from his swiftness of execution Fa Presto (b. 1632, d. 1705). He was a man of great ability, but his facility of invention and execution, and the readiness with which he could imitate different styles, led him to a slightness of manner which was fatal to greatness. Lanzi gives particulars of numerous later painters, some of whom are highly praised by Neapolitan writers.

(Among the authorities on the Schools of Painting in Italy may be cited Vasari, 'Vite de' Pittori;' Baldinucci, 'Notizie de' Professori del Disegno;' Della Vale, 'Lettere Senesi;' Bellory 'Vite de' Pittori;' Zanetti, 'Della Pittura Veneziana;' Domenici, 'Vite dei Pittori Napolitani;' Lanzi, 'Storia Pittorica della Italia;' Fiorillo, 'Geschichte der Malerey;' Speth, 'Kunst in Italien;' Rumohr, 'Italienische Forschungen;' Kugler 'Handbook of Painting in Italy,' edited by Sir C. L. Eastlake, and Wornum, 'Epochs of Painting.' The rise and progress of Italian pictorial design may be traced in the plates of D'Agincourt's 'Hist. de l'Art pas les Monumens' (Peinture); but still better in Ramboux's splendid series of 300 folio plates of outline tracings from the original frescoes of Italy from 1200 to 1600.)

Northern School: Germany.—Painting in Germany can be traced back to the time of Charlemagne, but few examples are extant of painters' works of a date prior to the 15th century. Charlemagne was a munificent patron of art. The dome of the cathedral erected by him at Aix-la-Chapelle he caused to be covered with mosaics representing Christ enthroned, with the four-and-twenty elders worshipping. The walls of his palaces glittered with representations of his own victorious, and other famous fields of battle; his oratories with sacred subjects, or legends of the saints; and miniatori exerted their best skill in illuminating manuscripts for his service. Of the paintings and mosaics no vestiges remain; but illuminated manuscripts of the period show that a considerable amount of imitative skill was reached, and in the scrolls and arabesque ornamentations not a little fancy, though the human face and form are as meagre and uncouth as in wholly Byzantine work. The Byzantine influence is, however, still more evident in German work of the 10th and 11th centuries, a consequence perhaps of the marriage of Otho II. (978–983) with the Greek princess Theophania having given the German artists access to the technical skill of the Byzantines. From the middle of the 12th and in the beginning of the 13th centuries, visible signs of new life in art began to show themselves. Ecclesiastical art took a wider scope; more artistic individuality was displayed; the drawing of the figure was improved, and expression was studied. The miniature painters especially made a marked advance, and many excellent examples of their work remain. In the 'Parcival' of Wolfram von Eschenbach, who lived early in the 13th century, the painters of Cologne and Maestricht are especially mentioned; and the series of compartments on the ceiling of the former monastery of Brauweiler, near Cologne, of about 1200, representing the 'Triumph of Faith,' and the figures of the Apostles, one of which bears the date 1224, in the church of St. Ursula, in Cologne, are, with those of scriptural subjects on the wooden roof of St. Michael's Church, Hildisheim, of the beginning of the 13th century, probably the oldest German pictures extant. But a more important work is the extensive series of paintings on the choir and transept of Brunswick cathedral, which appear to be of about the middle of the 13th century; and the paintings of saints recently discovered in restoring the transept of Bamberg Cathedral. (Kugler and Waagen.) A school of very able artists seems to have existed at this time in Bohemia; but towards the close of the 14th century the German painters recovered the lead, those of the school of Cologne being the most distinguished. Meister Wilhelm is spoken of by a contemporary chronicler, in 1380, as the best master of his day. Pictures attributed to him are to be seen in St. Castor, at Coblenz; some remarkably fine ones, formerly in the church of Sta. Clara, and now in the Cathedral of Cologne; in Cologne Museum; and in the Berlin Museum. The great altar-piece, formerly in the chapel of the town-hall, now in the cathedral of Cologne, is supposed to have been painted by Stephan Lothener, or as he was called, Meister Stephan, who died in 1451. The richness of the colouring, and the dignity and beauty of the Virgin, are most remarkable. Next to the schools of Cologne and Bohemia at this time ranks that of Nürnberg. A branch of the Cologne school appears about this time in Westphalia. Of this school the chief was a painter known as the Meister von Liesborn, whose great work was a large altar-piece in several compartments, painted for the second convent in Liesborn, but which was cut in pieces at the suspension of the convent by Napoleon in 1807; several of the pieces are lost; some are now, with other pictures of the master, in the National Gallery.

In the first half of the 15th century the German school departed little from the style it had previously followed, notwithstanding the great change introduced by the brothers Van Eyck into the practice of the painters of the Netherlands, with whom the German painters had always been closely associated. Traces of the influence of the technical improvements of the Van Eycks are indeed seen in the great work of Stephan Lothener: but the influence becomes much more palpable in the succeeding generation of painters, after the return of Martin Schongauer, and other Germans, from Brussels, where they had acquired, in the studio of Rogier Van der Weyden, the elder, a full initiation into the method of painting in oil as improved by the Van Eycks. It was, however, in the technics rather than in style that the influence of the Netherland masters was apparent. The old German nobleness of spirit was retained, but divested of some of the uncouthness of guise with which it had been disfigured; and its highest examples show great depth of thought and force of imagination, combined with singular faculty of invention and manipulative dexterity. The principal German painter of this period was Martin Schongauer, or, as he is commonly termed, Martin Schön (b. about 1420, d. 1488), and who was equally famous as a painter and an engraver. Genuine pictures by him are very scarce, those bearing his name being mostly old copies of his engravings. His most important painting is one of the Virgin in the church of St. Martin at Colmar. A small picture of the 'Death of the Virgin,' formerly in the collection of the King of Holland, an early work of Schongauer's, is in the National Gallery. Schongauer's pictures exhibit great knowledge of effect and a rich warm tone of colour. His fertility and vigour of imagination, and devotional feeling, are at least equally evident in his engravings; one of the most famous of these, 'St Anthony tormented by Demons,' is said by Vasari to have been copied by Michel Angelo. Other noted but inferior German painters of this time were, Frederick Herlen (d. 1491), Thomas Burgkmair; the elder Holbein; Bartholomew Zeitblom, in whom the style of Schongauer is seen sometimes carried to the verge of caricature, but sometimes raised to even a higher degree of earnest religious feeling; and Michael Wohlgemuth, of Nürnberg (b. 1434, d. 1539), a painter next to Schongauer in originality and power, though very unequal in his works, and the master of Albert Dürer.

The representative artist of the German school of the 16th century is Albert Durer (b. at Nürnberg 1471, d. 1528): one of the great artists of modern times. In feeling for ideal beauty, Dürer is far inferior to his great Italian contemporaries; in colour he yields both to the Italian and Flemish painters. But in originality of conception, fertility of imagination, invention, dramatic power, depth of thought, force of expression, and accuracy of drawing, he ranks with the highest. He might, in painting, almost be called the founder of the romantic, as opposed to the classic school. Sometimes his exuberant, almost inexhaustible, fancy runs into grotesqueness, and his designs are too often overloaded with fantastic and insignificant details. In grace and refinement he is very deficient. But there is often a subtlety as well as boldness of thought, which is very impressive when his meaning is fully understood; and these qualities are even more evident in his engravings and woodcuts than in his paintings—as, for example, in the marvellous designs of 'Death and the Knight' and 'Melancholia.' The British Museum has a very rich collection of Durer's engravings.

The earliest undoubted pictures of Dürer's are his portraits of his master, Wohlgemuth, and his own portrait in the Florence Gallery; among his latest and assuredly his finest works are the 'Apostles,' now in the Munich Collection. In 1506, Dürer visited Venice, but the Venetian school does not seem to have exercised a permanent influence over him, though a 'Virgin and Child,' with numerous kneeling figures, painted whilst there for the German Company, and some of the pictures painted shortly after his return to Germany, show that he appreciated the splendour of Venetian colour. [DÜRER, ALBERT, in BIOG. DIV.]

Dürer formed a large school of imitators, many of whose works in the various European collections are attributed to their great master. Among the principal of his Nürnberg disciples are Hans von Kulmbach, or Hans Wagner (d. 1540), several of whose pictures are in the churches of Nurnberg, while others are in the Munich and other German galleries; Hans Schäufflein (d. 1540), an artist of considerable imitative skill; Henry Aldegraver; Bartel Beham (b. 1496, d. 1540); Albert Altdorfer, so called from the place of his birth (b. 1488, d. 1538), the best and most original of all Dürer's scholars: his chief work, 'The Victory of Alexander over Darius,' is in the Munich gallery; and George Pencz (b. 1500, d. 1550), who went to Italy and studied under Raffaelle, and, while retaining something of the very different manners of both his teachers, displayed enough of his own to secure a place among the original painters of his country.

Saxony about this time produced, in Louis Cranach (b. 1472, d. 1553), a painter of great and various original talent, but more realistic in tendency than Dürer. Cranach was court painter to the three electors, Frederic the Wise, John the Steadfast, and Frederic the Magnanimous. He accompanied the first to the Holy Land in 1493, and shared the prison of the last after the battle of Mühlberg in 1547. At a later period he was burgomaster of Wittenberg, and a friend of Luther, whose marriage with Catharine von Bora he contributed to bring about. One of his most celebrated pictures, the 'Crucifixion,' an altar-piece at Weimar, contains portraits of Luther, Melancthon, and Cranach himself. His pictures are well-coloured, but fanciful, and the features of his females most singular. Lucas Cranach, the son, was also a painter, but without much originality; several of his pictures are in the churches of Wittenberg. Matthew Grunewald (d. at Aschaffenburg after 1530) was, after Dürer, one of the best and most original German painters of the first half of the 16th century; another was Hans Burgkmair, chief of the Augsburg school (b. 1473, d. 1559), and famous for pictures of knightly pageants as well as for ecclesiastical subjects: his pictures are very numerous.

Hans Holbein, the younger (b. at Augsburg 1498, d. 1554), divides with Albert Durer the rank of chief of the old German school; but, with invention scarcely if at all inferior to the great Nürnberg master, Holbein had less of the mediæval ecclesiastical spirit, and a less exuberant fancy. He is the type of old German realism: and, as in the case of Durer, his characteristic genius in design is more fully and powerfully developed in his engravings and woodcuts than in his paintings. He had less subtlety of thought, but a purer sense of physical beauty than Dürer; was even a more prolific designer, and was possessed of much greater versatility; so that he could paint with equal readiness in oil, fresco, and distemper, and acquired celebrity alike as a painter of historical and religious subjects, portraits and miniatures; while his woodcuts, especially the series so rich in subject and ingenious in treatment entitled the 'Dance of Death,' were beyond parallel popular among his countrymen. His best paintings in Germany are in the cathedral and the gallery at Augsburg, in the museum and private collections of Basel, the altar-piece in the cathedral of Freiburg, and at Darmstadt. Holbein came from Basel to England in 1527, and remained here (with the exception of a few brief visits to the Continent) during the rest of his life, dying in the service of Henry VIII. In this country he executed comparatively few historical or biblical paintings, but a vast number of portraits (both oil paintings and chalk drawings), including the court, and most of the illustrious personages of the time. The royal collections at Windsor and Hampton Court contain a large number of the works executed by him whilst in England, but many are lost, including his two great pictures in tempera, 'The Triumph of Riches,' and 'The Triumph of Poverty,' painted for the company of German merchants in London, but which were presented by the company to Prince Henry of Wales in 1616, from which time all trace of them is lost. These were considered by Federigo Zucchero, who made a copy of them, to be equal to the works of Raffaelle; and the drawing in the British Museum shows that they must have been amongst the finest works of their class ever produced. One of his most noteworthy pictures is in the hall of the Barbers' Company, London; it is a composition representing eighteen members of that guild receiving a grant of privileges from Henry VIII. [HOLBEIN, HANS, in BIOG. DIV.] Holbein had many followers, among whom the most celebrated were, Nicolas Manuel, a Swiss (b. 1484, d. 1531), and Martin Schaffner (flourished 1499-1535), whose chief works are in the cathedral of Ulm, the chapel of St. Maurice at Nürnberg, and the Munich gallery. From this time dates the decline of German art. Already its distinctive character was being lost in a general and feeble imitation of the Italian masters, the best painters being those who, like Johann Rothenhammer (b. at Munich 1564, d. 1623) and Adam Elzheimer (b. at Frankfort-on-the Maine 1574, d. at Rome 1620), painted cabinet pictures, in a light graceful manner which has always found many admirers; their works consequently are in most public galleries, and many are in the private collections of this country.

The German painters of the 17th century were nearly all scholars of the Dutch and Flemish genre and landscape painters, or scholars and imitators of the Italian eclectics and naturalisti, while many of them resided permanently in the Netherlands or Italy. It will suffice, therefore, to mention Joachim von Sandrart (b. 1606, d. 1688), who painted every variety of subject in every variety of style, but who is now best known as the writer of a series of Lives of Painters, which has preserved much valuable information respecting his Italian contemporaries as well as his countrymen; Heinrich Schonfelds (b. 1609, d. 1675), equally versatile, prolific, clever, and without distinctive character as Sandrart; Heinrich Roos, much admired as a landscape painter; and his son Philip Roos, better known as Rosa di Tivoli (b. 1655, d. 1705).

In the 18th century, painting in Germany, as throughout Europe, was coldly academic and conventional, and devoid of all invention, originality, and feeling. Yet whilst thus merely imitative, the perception of harmony of colour, so characteristic of the painters regarded as models, was wholly wanting, and its absence seems scarcely to have been suspected. Even in the mechanism of the art there was marked degradation. Christian Rode (b. 1725, d. 1797), Johann Henry Tischbein (d. 1789), and Raphael Mengs (b. 1728, d. 1774), are among the few painters of the century whose names are still remembered. Mengs, extravagantly praised in his life-time, is now remembered as merely the type of a correct and accomplished academic painter—without a spark of genius or spontaneous feeling—the artistic law-giver of his age, and the author of some carefully considered, learned, and well-written treatises on painting. His pictures abound in the Continental galleries. Angelica Kaufmann (b. 1742, d. 1807), though German by birth, practised her art chiefly in England, and was one of the original members of the Royal Academy—ladies in the early days of that institution being allowed to append to their name the coveted distinction of R.A. All her pictures are respectable: their value may be estimated from the characteristic example in the National Gallery. Solomon Gessner (b. 1734, d. 1788) has made himself remembered as a painter by his celebrity as a poet; whilst Dietrich (b. 1712, d. 1774) and Chodowiecki (b. 1726, d. 1801) have acquired a certain reputation from the universality of their efforts and the commendations of their contemporaries. Elias Riedinger (b. 1695, d. 1767) claims mention as a clever painter and still more clever draftsman of animals and hunting-pieces; and Balthasar Denner (b. 1685, d. 1749) as a painter unrivalled for minuteness of detail, his hideous portraits having every freckle, wart, or wrinkle imitated with an accuracy that will bear examination with a magnifying glass.

The great revival of German painting in the early part of the present century, commenced by the exertions of a small band of zealous students then residing in Rome, with the result of the subsequent reaction against the excessive ecclesiasticism and mediævalism of the authors and supporters of the movement, can only be alluded to here. Some account of the movement, and of the principal actors in it, will be found under the names of CORNELIUS, OVERBECK, SCHADOW, VEIT, SCHNORR, LESSING, &c., in the BIOG. DIV.

Painting in the Netherlands.—The divergence of the schools of the Netherlands from those of Germany dates from the beginning of the 15th century. The founders of the Flemish school were Hubert and Jan van Eyck (b. 1366, d. 1426, and b. 1400, d. 1445), who united the majestic simplicity of the old Christian type with a close imitation of external nature and a homely strength characteristic of their country. Their brother Lambert and sister Margaret were also artists. (Carton, 'Les Trois Frères van Eyck.') Hubert van Eyck may be said to have so far improved the method of painting in oil, as almost to be entitled to the honour, long accorded by mistake to his brother, of being its inventor. (See Eastlake's 'Materials for a History of Oil Painting,' where the question is fully investigated.) The great work of the brothers, it having been commenced by Hubert and finished by Jan, was the altar-piece in St. Bavo at Ghent, painted for Judocus van Vyt. It consisted of a centre picture of the Worship of the Lamb, surmounted by God the Father, the Virgin, and St. John, and flanked by folding shutters, all relating to the principal subject. The different parts of this painting, unquestionably one of the most remarkable productions of modern art, are now separated. The upper and middle portions remain at Ghent; the others are at Berlin. Michael Coxis executed a copy of it for Philip II., which is still more scattered. [Eyck, Hubert Van, in Biog. Div.] Two noble works by Hubert are the 'Triumph of the Church,' in the Museum of Madrid, and 'St. Jerome,' in the gallery at Naples, long attributed to Col-Antonio del Fiore. Jan van Eyck, though he has acquired a wider fame than his brother—in a great measure from his being regarded as "the inventor of oil-painting"—was a much less imaginative painter; but he carried the technics of painting far beyond any predecessor, and some of his pictures still remain in an almost perfect state of preservation—as, for example, that, dated 1434, of a man and woman (supposed to be portraits of himself and wife), in the National Gallery, which is one of the most admirable examples of his style.

The school of the Van Eycks was fertile in good painters, and their influence extended wherever painting was practised. One of the oldest of their scholars in the Netherlands was Justus Van Ghent; others of considerable celebrity were Dierick Steurbout, or Dierick Van Harlem, two altar-pieces by whom are in St. Peter's, Louvain, and some large paintings from the legend of the emperor Otho are in the Town Hall of the same city; and Hugo van der Goes, of Ghent, who is mentioned by Vasari, and some of whose pictures found their way to Italy. But the most distinguished of the scholars of Jan van Eyck, and one who by his numerous pupils did more than any other to extend the influence of the school, was Rogier van der Weyden, better known as Roger of Bruges (d. 1464). One of his finest works, a 'Last Judgment,' is in the hospital of Beaume; another, the 'Adoration of the Kings,' in the Pinacothek at Munich; and several admirable pictures by him are in the Berlin museum; others are in Antwerp, Brussels, Paris, and London. Chief among the scholars of Rogier was Hans Memling, perhaps the most eminent of the Netherlands' painters in all that respects refinement of feeling, beauty of form, and tenderness of expression. Some very beautiful works by him are preserved in St. John's Hospital, Bruges, of which he was an inmate about 1479. In the church of Our Lady at Dantzic is a large altar-piece, 'The Last Judgment,' a work of great extent and vigour, and probably the most important example of his pencil. Several of his pictures are at Munich. The traditions of the school were continued into the next century by Rogier van der Weyden the younger, Goswin van der Weyden, De Witte, Gerhart, Jan Gossaert, or Jan Mabuse, Jan Mostaert, and others, but towards the middle of the 16th century the Van Eyck influence had been nearly superseded.

Of the Antwerp painters of this time, the most famous is Quentin Massys, or Matsys, 'the Blacksmith' (b. 1460, d. 1530), one of the earliest painters of those homely subjects for which the artists of the Netherlands afterwards became so celebrated. His 'Misers,' of which there is a replica at Windsor Castle, is a well-known example of his style; but he also painted religious subjects, of which class the 'Virgin and Child' in the National Gallery is a favourable example. But his masterpiece, a 'Deposition from the Cross,' is in the Antwerp Museum. Luc Jacobez, or Lucas Van Leyden (b. 1494, d. 1533), was one of the ablest and most versatile artists of his time. The 'Last Judgment,' in the Town House of Leyden, is his most important work. But he appears to most advantage in his engravings, which are as numerous as his paintings are scarce.

The later works of Jan Mabuse (b. 1499, d. 1562), and the pictures of Jan Schoreel (b. 1495, d. 1562), Michael Coxis (b. 1497, d. 1592), Martin van Neen, or Martin Hemskerk (b. 1498, d. 1574), and Lambert Susterman, or L. Lombard (b. 1506, d. 1560), show that forced imitation of the Italians which characterises the transition from the old Flemish to the school of Brabant. This tendency is more strongly marked in Franz Floris (b. 1520, d. 1570), in the elder and younger Francks, in Bernhard van Orley (b. 1471, d. 1541), Heinrich Goltzius (b. 1588, d. 1617), still more famous as an engraver than a painter, Pieter de Witte, and Otho Venius (b. 1556, d. 1634), the master of Rubens. The works of these artists and their contemporaries—Abraham Blomart (b. 1564, d. 1647), Cornelis van Harlem, Van Balen, and others—are deficient in independence and genuine feeling, though they interest us as being the groundwork of the school of Rubens. Among the portrait painters of this time are several who acquired even more celebrity in this country than in their own. Of these, we may mention Sir Antony Moro (b. 1518, d. 1588), who, as painter to Philip of Spain, resided at the court of Mary, and painted portraits of the Queen, Lord Essex, Sir Henry Sidney, and other courtiers; Paul van Somer (b. 1576, d. 1624), who painted Lord Bacon and other of the distinguished men at the court of Elizabeth; Mark Gerard (d. 1635), the favourite painter of Elizabeth and her courtiers; Daniel Mytens, who painted James I. and Charles I.; and Cornelius Jansen, who succeeded Mytens as court painter.

The Netherlands witnessed, in the commencement of the 17th century, a revival of painting more striking than that effected by the Caracci. Peter Paul Rubens was born at Cologne in 1577, and died at Antwerp in 1640. After leaving the school of Otho Venius, he visited Italy, and studied particularly the works of Titian and Paul Veronese. His system of colour was based on that of the Venetians, and was only inferior to theirs. His forms are gross, but always full of life and vigour. His later pictures exhibit increased knowledge of effect, but the earlier are more attractive than those which were executed when the overwhelming number of commissions obliged him to employ unsparingly the pencil of his pupils. The 'Descent from the Cross,' in the cathedral of Antwerp, and its companion, are deservedly cited as among the best specimens of the master. His works may be studied in the greatest perfection in the museum and church of Antwerp, in the gallery of Vienna, and more especially at Munich. But almost every important Continental gallery contains paintings by him. Our own country contains a large number of his works. Among private collections, that at Blenheim is peculiarly rich in first-rate pictures by Rubens. The National Gallery possesses several of great excellence. Rubens is equally great in history, in landscape, and in portrait. To complain that the fire of his genius was not chastened as in the great Italian masters, is to wish that the artist had been a different individual from what he was formed to be. When we look at Rubens's works, their facility of execution, their energy, and their brilliancy hurry us beyond such considerations; when we think of them, we may regret that his forms are often ill-selected, that the brute animal vigour of his bacchanals is pushed to coarseness, and that the physical prevails so generally over the spiritual. [Rubens, in Biog. Div.]

The most celebrated of the pupils of Rubens was Antony Vandyck (b. 1599, d. 1641). At first he imitated closely the peculiarities of his master; but after his residence in Italy he adopted a more tranquil tone of feeling and soberer colour. His historical pictures have many excellent qualities, but they are not equal in their way to the numerous and admirable portraits, many of which were executed during a residence in England, and still remain in this country. [Vandyck, Antony, in Biog. Div.]

Of the other scholars of Rubens, few did more than imitate, and sometimes exaggerate, the outward characteristics of their leader, with the exception of Frans Snyders (b. 1579, d. 1657), who, as a painter of animals in vigorous action, has never been equalled. After Vandyck and Snyders, the best among Rubens's scholars were perhaps Jacob Jordaens (b. 1594, d. 1678), and Gaspar de Crayer (b. 1585, d. 1669).

In Holland, Michael Mirevelt (b. 1567, d. 1641) and Franz Hals (b. 1584, d. 1666) painted history and portraits, especially the latter, with great success. Barthol. van der Helst (b. 1613, d. 1670) approached very closely to Vandyck in colour. His finest work, the 'Festival given by the Burgher-guard of Amsterdam on the conclusion of the Treaty of Westphalia,' is in the museum of that city. Another excellent picture of smaller dimensions is in the Louvre.

The great master of the Dutch school, however, was Paul Rembrandt van Ryn (b. 1608, d. 1674). In his portraits and ideal heads we find the most wonderful truth and dignity; but his peculiar power consisted in a mastery of light and shade, which rendered the lowest subjects vehicles for high and poetical feeling. The depth and brilliancy thus produced seem hardly attainable by mere colour on a flat opaque surface; and when we look at his numerous etchings, we marvel still more how his needle on the copper has almost surpassed his pencil on the canvas. Conscious of his power to attain sublimity by light and shade alone, he seems often to have rejoiced in showing how that one charm could make us heedless of coarseness of conception and meanness of form. [Rembrandt, in Biog. Div.] Rembrandt's principal pupils and imitators were Gerbrand van den Eeckhout (b. 1621, d. 1674), Ferd. Bol (b. 1611, d. 1681), who excelled in portrait, Nicholas Maas (b. 1632, d. 1693), and Salomon Koning (b. 1609, d. about 1674), who in all his best qualities approached nearest to his master. Of another pupil, Gerard Dow, we shall speak immediately.

It is necessary just to mention Gerard Honthorst, called by the Italians Gherardo delle Notti (b. 1592, d. 1662), who imitated Caravaggio and the Italian "Naturalisti." His effects of torch and candle light are much celebrated. Gerard Lairesse (b. 1640, d. 1711) is best described as a Flemish imitator of Nicolas Poussin. Adrian van der Werff (b. 1659, d. 1722) has little to recommend him besides a finish and smoothness of surface, to which higher qualities are sacrificed: his human figures present the texture of ivory rather than of flesh, with much affectation and little genuine expression of passion or character.

We must now turn to those masters who are most distinguished in what is called "genre," a word for which it is difficult to find a substitute, and still more difficult to furnish a definition. The subject may be real or fictitious; but if the picture is on a small scale, and the object of the artist has been the expression of humour, or the prettiness of colour, or of light and shade,—if these qualities which are accessories in great works have been to him ends—then it seems to come within the negative class, designated by the French word used above. It is the popular side, the every-day life of art, as contrasted with the epic grandeur of historical or the enthusiasm of devotional works.

Peter Breughel the elder (b. 1510, d. 1570) was called Boor-Breughel, from the subjects of many of his pictures, as his son, Peter Breughel the younger, obtained the name of Hell-Breughel, from the fantastic scenes which he pourtrayed; while a younger brother, Jan Breughel (b. 1568, d. 1625), is known as Velvet-Breughel, from the softness and delicacy of his handling: he painted animals and flowers even better than genre. The elder Teniers (b. 1582, d. 1649) delighted in subjects similar to the elder Breughel's; but as a painter he by no means equalled his son and pupil David Teniers (b. 1610, d. 1690) in those scenes of merry-making and peasant life for which he is so celebrated. Nothing can surpass the reality of the vulgar comfort with which the single figures sit and smoke, or the drunken gaiety of the larger assemblies, in the pictures of the younger Teniers. His colour is cool and his touch firm and vigorous. Sometimes he amused himself with imitating the works of masters of a different cast. In Adrian van Ostade (b. 1610, d. 1685) we have the same subjects treated in a warmer and more mellow tone, but perhaps with less individual truth and character, though with greater attention to general effect, than by Teniers. Isaac van Ostade painted fewer interiors, and followed his brother's style with less success. The humour of Adrian Brouwer (b. 1608, d. 1640), who is reported to have mixed deeply in the scenes which he painted, is of a broader cast. In Jan Steen (b. 1636, d. 1689) there are satirical touches and a genuine comic unity which remind one of Hogarth, though there is little of the Englishman's stern moral purpose. There is another department of genre, which bears the same relation to the drinking-bouts of Teniers or Brouwer that genteel comedy does to broad farce. In this Gerard Terburg and Gerard Dow stand pre-eminent. The former (b. 1608, d. 1681) threw into the scenes which he represented a delicacy of feeling and a sort of decorum which add greatly to the value of his execution and high finish. Of this kind are the celebrated Satin Gown, engraved by Wille; the Trumpeter at Munich; and the Cavalier and Lady in the Louvre. Gerard Dow (b. 1613, d. 1680) was the pupil of Rembrandt, from whom he gained a thorough knowledge of light and shade, and a feeling for general effect which preserved his elaborate execution from tediousness, while he secured by it a wonderful reality in the household scenes which he delighted to paint. In some of his pictures, as in that of the Dropsical Lady, there is even pathos. Gabriel Metzu (b. 1615, d. 1658) was the best imitator of Terburg. Franz Mieris, a scholar of Gerard Dow (b. 1635, d 1681), equalled his master in fineness of finish, but not in genuine feeling. Caspar Netscher (b. 1639, d. 1684) and Eglon van der Neer (b. 1643, d. 1703) painted in the same style. The interiors of Peter van Hooghe (b. 1659, d. 1722) are remarkable for magical effects of light.

The great Italian painters Giorgione and Titian were admirable in landscape. Annibale Caracci and Domenichino have left excellent pictures in this department. But as if the ugliness of the country stimulated its natives to study all the aids which make an ordinary scene picturesque, it was in Flanders and in Holland that landscape painting was most cultivated. In the school of Van Eyck, the backgrounds are often elaborately imitated from nature: Joachim Patenier (b. 1487) and Herri de Bles (b. 1480, d. 1550) executed works in which the landscape claims an independent existence, and the figures have already become accessories. Jan Breughel, or "Velvet-Breughel," as has been mentioned, copied with wonderful minuteness all the variety of vegetation. Contemporary with Annibale Caracci there lived at Rome a Flemish artist, Paul Bril (b. 1554, d. 1626), who forms a sort of link between the landscape painters of the north and south.

In that kind of landscape the excellence of which consists in grandeur and the form of the large masses, Nicolas Poussin led the way. He was followed by Gaspar Duget, or Poussin (b. 1600, d. 1663), and Sebastian Bourdon (b. 1616, d. 1671). Claude Gelée was a native of Lorraine (b. 1600, d. 1682); he was first educated by A. Tassi, a scholar of Paul Bril, but nature, and nature alone, taught him to tinge his graceful forms of foliage and his rippling water with the cool pearly hue of morning, or the rich glow of an Italian evening. His pictures acquired in his lifetime the value which they have ever since maintained.

The style of Claude reacted on the Low Countries. Hermann Swanevelt (b. 1620, d. 1680) was his pupil: John Both (b. 1610, d. 16[illegible]) and Adam Pynacker (b. 1621, d. 1673) were painters of the same character. The Dutch landscape painters kept closer to Northern nature; such are the works of John van Goyen (b. 1596, d. 1656); generally low sea coasts, executed in a brown transparent tone. Anthony Waterloo (b. 1618, d. 1660) is better known by his admirable etchings than by his pictures.

The genius of Rembrandt exercised considerable influence over landscape; and he was admirably followed by his pupil Philip de Koninck (b. 1619, d. 1689), who in broad, open, flat landscapes, often equalled, and sometimes surpassed, Rembrandt himself. But the leaders of this particular school were Jacob Ruysdael (b. 1635, d. 1681) and his pupil Mindert Hobbema (b. 1611). The best works of these masters carry us into the depth of the forest, and convey that sort of lonely feeling which retired woodland scenery imparts. Albert Everdingen (b. 1621, d 1675) gave his pictures more of the Norwegian character, and often painted water falls and pine-forests.

We have said nothing of the pastoral side of landscape, in which Nicolas Berghem (b. 1624, d. 1683), Albert Cuyp (b. 1606), Carl du Jardin (b. 1640, d. 1678), and Adrian van der Velde (b. 1639, d. 1672), excelled. Philip Wouvermans (b. 1620, d 1668) pursued a line peculiar almost to himself, or in which at least he has no rival. He executed battles, fairs, halts of cavalry, and all scenes in which horses occur, with truth and delicacy.

The most eminent marine painters were Bonaventura Peters (b. 1614, d. 1652), Ludolf Backhuysen (b. 1631, d. 1709), and William van der Velde (b. 1610, d. 1693). John Fyt (b. 1625, d. 1700), and John Weenix (b. 1644, d. 1719), painted animals; while De Heem, Van Schriek, Vromans, and others, devoted themselves with equal zeal to painting flowers, insects, &c., De Heem being, all things considered, the first in his line.

In the 18th century, painting was in Flanders and Holland as coldly imitative and conventional as elsewhere. Adrian and Pieter van der Werff, and Hendrick van Limborch, produced academically correct historical pictures; Jacob de Wit displayed extraordinary dexterity in making his canvases look like bronze relievi; the elder Van Mieris painted portraits and flowers; the younger wrought mythological subjects and poultry yards; the Van Nickelens, father and son, painted architecture and landscape; and Van Huysum flowers, with a truth and taste only inferior to De Heem. The schools of Belgium and Holland were somewhat late in arousing themselves from the slumber into which they had fallen in the last century; but at the present time painting is nowhere more earnestly and diligently, nor in some of its branches more successfully followed, than in Belgium.

(The most recent and comprehensive general survey of the history of the Northern schools, is Kugler's 'Handbook of Painting: German, Flemish, and Dutch Schools,' as recast by Waagen, Lond. 1860. See also Cavalcaselle and Crowe's 'Notices of the Early Flemish Painters;' Sandrart's 'Academia;' Descamps, 'La Vie des Peintres Flamands, Allemands, et Hollondais,' Par. 1753; Michiel's 'Histoire de la Peinture Flamande et Hollondaise,' Bruxelles, 1845-6; 'Hist. de l'Ecole Flamande,' Bruxelles, 1856; and Wornum's 'Epochs of Painting.')

The Spanish School of Painting cannot be carried back farther than the first half of the 15th century, though it is certain that miniatori were employed in illuminating manuscripts as early as the 10th and 11th centuries. The cradle of Spanish painting was Toledo. The Castilians borrowed something from the Byzantines, with whom they had much intercourse. But, as might be expected, the Flemish painters exercised a far more powerful influence in Spain. Two Flemish painters are especially singled out: Maestro Rogel (who was in Spain in 1445), who is identified by some with Rogier van der Weyden; and Juan Flamenco (1496), whom some, without much reason, suppose to be Hans Memling. Somewhat later, Titian, who spent some years in Spain in the service of Charles V., helped to mould the Spanish painters' principles of colour.

Luis de Vargas (b. 1502, d. 1568) was one of the first conspicuous Spanish painters. A thorough devotee, he helped to foster that ascetic tendency, and that entire subserviency to ecclesiastical canons, which formed so marked a feature in early Spanish painting. The works of Luis de Morales of Badajoz (b. about 1510, d. 1586) show some traces of early Flemish minuteness and hardness, with great power of expression, occasionally exaggerated: from the devotional character of his pictures, which are chiefly of the Saviour crowned with Thorns, or the Madonna Weeping, Morales has acquired from his countrymen the surname of "the Divine." Fernando Gallegos imitated Albert Dürer. Antonio del Rincon (b. 1446, d. 1500), Alonso Berruguete (b. 1480, d. 1562), Pedro Campaña, a Fleming by birth (b. 1503, d. 1580), Gaspar Becerra (b. 1520, d 1570), Pablo de Cespedes (b. 1538, d. 1608), and Vincente Joannes of Valencia (b. 1523, d. 1579), who is regarded as the head of the school of Valencia, were the earlier Spanish masters of eminence who studied in Italy; the ablest, and certainly the most influential, being Berruguete, and next to him Gaspar Becerra.

The works of Rincon are rare: there is an altar-piece of his at Robledo de Chavela, not far from the Escurial. Campaña's Descent from the Cross, and the celebrated Gamba of Vargas are in the cathedral of Seville. The series of the Martyrdom of St. Stephen, by Joanes, is in the museum of Madrid. Alonso Sanchez Coello (d. 1590) and Juan Fernandez Navarrete el Mudo (b. 1526, d. 1579) painted respectively portraits and sacred subjects for Philip II. The colouring of Navarette is very fine, and resembles that of the Venetian school.

In the school of Seville, in the 17th century, the principal forerunners of Murillo were Juan Sanchez de Castro; Juan de las Roelas (b. 1558, d. 1625), who studied in Italy, and whose finest picture is perhaps the Death of St. Isidore, in the church of that saint at Seville; the two Herreras, and Francisco Zurbaran (b. 1598, d. 1662). The elder Herrera (b. 1576, d. 1656) is distinguished by vigour and boldness of execution. Zurbaran's great work of St. Thomas of Aquino, formerly in the Colegio de Santo Tomas, will bear comparison with the best pictures of any master. Bartolomé Esteban Murillo (b. 1618, d. 1682) has left early pictures at Seville which give little promise of his subsequent excellence. It was only after his return from Madrid in 1645 that he attained that freedom and power which characterise his best works. The name of Murillo is supposed by many in this country to stand highest in the Spanish school, but Diego Velasquez de Silva (b. 1599, d. 1660) was perhaps the greater man, though Murillo painted loftier as well as humbler subjects. The portraits of Velasquez are only equalled by those of Titian: his historical works in the Madrid Gallery, such as the Surrender of Breda, and his sketches of landscape in the same collection, are of great excellence. One of his most celebrated early pictures is the Water-carrier, now at Apsley House. His style, however, often runs into excess, bordering in its sternness on the violent contrasts of Caravaggio, but always avoiding his vulgarity.

Francesco Pacheco (b. 1571, d. 1654) was the founder of the school of Seville. His scholar, Alonso Cano of Granada (b. 1600, d. 1667) painted with simplicity and beauty, as well as vigour. Francisco Ribalta (b. 1551, d. 1628) is generally held to be the best master of the Valencian school. The altar-piece in the chapel of Magdalen College, Oxford, is probably by him. Claudio Coello (d. 1693) is one of the last Spanish masters who deserve notice. His picture in the Sacristy of the Escurial is a brilliant work.

The Spanish school can boast of several painters who may rank with the best of any other country. But Spanish painting was always limited in its scope, and was early exhausted. From the first it was eminently religious, and ascetic in its religion. It has been said that a nude figure does not probably occur in Spanish painting: and the most stringent rules were laid down by the ecclesiastical authorities for the treatment of the sacred and saintly personages introduced by artists on their canvases. The favourite subjects were connected with the mysteries of religion, the legends of the saints, and especially religious ecstacies. Though Murillo painted peasant boys with infinite relish, his greatest works are such as 'the Immaculate Conception,' or the 'Assumption.'

(Cean Bermudez, 'Diccionario Historico;' Stirling's 'Annals of the Artists of Spain;' Kugler's 'Hand-book: Spanish Schools,' ed. by Sir E. Head).

French School.—France, in the reign of Charlemagne and subsequently, had its miniature painters, and, as we see by the sculpture on its Gothic churches, always possessed a decided feeling for art. But the French can scarcely be said to have had a school of painting of their own until a comparatively late date. In the 16th century, Jean Cousin and the family of the Clovets were painters, who owed little to foreign teaching, but with these exceptions, the older French painters either studied and practised in Italy, or were mere imitators of Italian painters; while many Italians were either temporary or permanent residents in France. Among these were Lionardo da Vinci, Andrea del Sarto, Rosso, and Primaticcio, whom the zeal of Francis I. introduced into France. We find little independent existence of French painting before Simon Vouet (b. 1582, d. 1641), who studied the later Venetian painters, and Caravaggio: he was regarded as one of the first painters of his time, and was the master and model of the succeeding generation of French painters. His contemporary Nicolas Poussin (b. 1594, d. 1665) stamped a character on the art of his country which may be said to have lasted almost to our own days. His style is based in some degree on a confusion of the capabilities of sculpture and painting—statuesque forms, fine drawing, and the composition of a bas-relief clothed in unpleasing colour, though not wholly satisfactory to the eye, still combine to produce considerable effect; an effect however of a limited kind, analogous to that resulting from the classical correctness of Racine's tragedies, and without any life or spontaneity. Gaspar Poussin and Claude Lorraine, have been already named: they both learned their art in Rome and there practised it. The most famous of Vouet's scholars were Eustache Le Sueur (b. 1617, d. 1655), called the 'French Raffaelle,' a title sufficiently characteristic; and Charles Le Brun (b. 1619, d. 1690). The large pictures of Le Brun are very clever but disfigured by the affectation of the time of Louis XIV. Peter Mignard (b. 1610, d. 1695), another pupil in the same school, painted some good portraits. Antoine Watteau (b. 1684, d. 1721) is celebrated for the piquant grace of his courtly garden scenes and fêtes galantes. A clever imitator of his style was Nicolas Lancret (b. 1690, d. 1740), whose pictures, though wanting the *abandon*, are not seldom taken for those of Watteau. François Lemoine (b. 1688, d. 1737) was an imitator of Pietro da Cortona. Joseph Vernet (b. 1711, d. 1789) executed some very clever landscapes and sea-pieces, though for the most part disagreeable in colour. J. B. Greuze (b. 1726, d. 1805) excelled in the representation of scenes of domestic life, and in female portraiture; his style verges on the meretricious, but his pictures continue to increase in favour with the collectors, both of England and France. Under Coypel, Lemoine, Vien, Boucher, and Vanloo, Parisian art went on steadily deteriorating. It owes its resuscitation to the general mental excitement produced by the stirring wants of the revolution; but the special form which it assumed was due chiefly to the energy and tact of Jacques Louis David (b. 1748, d. 1825); though his pictures are in a thoroughly mistaken style. He endeavoured to carry out on a larger scale the "classical" principles of Poussin. It is impossible to deny his pictures the merit of fine drawing and a certain power; but disagreeable colour, exaggerated theatrical expression, and academic affectation mar the effect of their better qualities. His most eminent followers were Gérard, Gros, Girodet, Droling, Pujol, Guérin, and Géricault. Guérin carried the system of his master to the verge of caricature, and thus hastened the inevitable reaction. Gérard was a painter of considerable power, but marred by conventionalism, and utter want of feeling for colour. Some of his portraits are eminently characteristic; his huge transcripts of contemporary history are as eminently artificial.

Among the great leaders in the reaction, and the masters to whom the present position of French painting is mainly attributable, it must suffice to mention Jean Louis Géricault, Leopold Robert, Ary Scheffer, and Paul Delaroche, who have passed away; but Delacroix, Ingrez, Horace Vernet, and others, who still survive, have an equal title to rank among the pioneers of contemporary French art.

English School.—We have ample evidence that the English were among the earliest and warmest patrons of the art of the mediæval miniature painter; and manuscripts like the famous 'Durham Book' in the British Museum show that even in the 8th century British miniatori were at least equal to their brethren on the continent. In the 10th century English manuscripts were eagerly sought for abroad, and their mode of ornamentation was known as "English Work," (Opus Anglicanum): of this style and time is the beautiful Benedictional of St. Ethelwold, in the possession of the Duke of Devonshire. In the succeeding centuries the same excellence was maintained, and those who have devoted special attention to this branch of art remark that English miniatures are purer and richer in style, and freer from Byzantine characteristics than continental manuscripts of the same date. The art gradually passed out of use, but it is noteworthy that in the form of miniature portrait-painting which succeeded the decoration of missals and service books, English artists for some time maintained a decided superiority.

But of painting proper, though there is reason to believe that the paintings in mediæval churches and on the walls of palaces were frequently the work of native hands, there was no school founded in England till long after every other great European country. Henry VII. employed John Mabuse, Henry VIII. for many years retained Holbein, and after his death Sir Antony Moro as his court painter; and as we have already seen, succeeding monarchs usually had one or more distinguished foreign portrait-painters in their service. But it was long before an English painter was found to enter into competition with any of them even in this comparatively facile and always lucrative branch of art. In the reign of Elizabeth, two Englishmen, Nicholas Hilliard, and his pupil Isaac Oliver, acquired distinction as miniature painters. Hilliard imitated the manner of Holbein, but Oliver was more original, and was admitted to be, in his own line, one of the very best artists of his age. His son, Peter Oliver, was also a skilful miniature-painter.

Charles I. was an eager and an intelligent collector of pictures, and he invited to England Rubens, Vandyck, Hontherst, Gerbier, and many other painters of contemporary celebrity. His example was followed by his wealthier courtiers, and English as well as foreign painters soon became recipients of their patronage. The foreign painters represented every branch of the profession; but the Englishmen confined themselves almost exclusively to portraiture: Francis Barlow, an animal painter, being one of the few exceptions. But in portraiture English painters were strong. Robert Walker, who was patronised by Cromwell, painted a head nearly as well as Vandyck; while William Dobson (b. 1610, d. 1646) who was distinguished as "the English Tintoret," and succeeded Vandyck as sergeant-painter to the king, is in some of his best portraits little inferior to either of the great painters named in conjunction with him: his portraits are comparatively numerous. Other English portrait-painters were Nicholas Stone the younger (but best known by the cognomen of Old Stone), who studied in Italy, and was celebrated as a colourist; George Jameson, "the Scottish Vandyck," Richard Gibson the Dwarf, and Samuel Cooper (b. 1609, d. 1672) one of the greatest miniature-painters of any time.

Several of these lived to practise their art under Charles II., but neither in the reign of that monarch, nor in that of his successors did English painting find patronage, or indeed seek it. England was not wanting in painters, but among them not a single English name of eminence occurs till that of Hogarth. Lely and Verrio were the court painters to Charles II. and his brother; and to Lely succeeded Sir Godfrey Kneller as the royal and fashionable portrait-painter, while Laguerre followed Verrio as the manufacturer of those monstrous allegories with which it was the fashion to disfigure the staircases and ceilings of palaces. To these indeed Englishmen were the successors, but Jervas, Thornhill, and Hudson only served to carry a step lower the degradation of painting. Yet though painting in England was in a course of steady decline from the Restoration to the reign of George II., there were numerous English painters, some of whom it may be proper to mention. One of these was John Riley (b. 1646, d. 1691) court painter to William and Mary: he was perhaps the best imitator of the manner of Lely. Henry Cooke (b. 1642, d. 1700) is said to have studied under Salvator Rosa; he painted the chapel of New College, Oxford, and "restored" for William the cartoons of Raffaelle, without doing them much injury. Jonathan Richardson (b. 1665, d. 1745), who married the niece of Riley, and acquired that painter's traditions, was a respectable and prosperous portrait-painter; a great admirer of the works of the old masters, and of choice engravings, of which he formed an excellent collection; and the author of some very intelligent essays on the Theory of Painting, which are said to have contributed largely towards making Sir Joshua Reynolds a painter, and may still be read with profit. Charles Jervas, so extravagantly praised by Pope, was the leading portrait-painter of his day, but is now only noteworthy as a striking example of the influence of fashion. Sir James Thornhill was the first Englishman who met with extensive patronage in any other branch of painting than portraiture, and it was long before the example was followed. It will be enough to refer to Thornhill's paintings in the hall of Greenwich Hospital, and on the dome of St. Paul's as illustrations of his style. Thomas Hudson is only memorable as the master of Sir Joshua Reynolds.

The true regenerator of English art, and the first really great English painter, was William Hogarth (b. 1697, d. 1764), in his chosen line of moral satire one of the most original painters who ever lived. In Hogarth's day, and almost till the present time, it was usual to speak of him in the words of Walpole, as having "but slender merit as a painter." But his technical merits are better appreciated now, while as a humourist, a shrewd observer of contemporary life, and a master of ludicrous expression in face and form, he is acknowledged to be without equal. [HOGARTH, WILLIAM, in BIOG. DIV.]

The actual head of the British school of painting, however, was Sir Joshua Reynolds (b. 1723, d. 1792), the ablest and most intellectual portrait painter and the greatest colourist this country has produced, and not unworthy to rank with the best portrait painters and colourists of any country; it is only to be regretted that, owing to his imperfect technical training, so many of his works are already decayed or decaying. His historical paintings are only valuable as examples of his powerful colour and facile handling. Sir Joshua was the first president of the Royal Academy (founded in 1768), and in that capacity delivered the 'Discourses,' which have scarcely exerted a less powerful influence on English art than the productions of his pencil. [REYNOLDS, SIR JOSHUA, in BIOG. DIV.]

Thomas Gainsborough (b. 1727, d. 1788) was inferior to Reynolds as a painter of male portraits, but in expressing the lighter graces of the female face and form he was at least his equal. But his great original power lay in painting English cottage-doors, woodland landscapes, watering places, and similar simple rustic scenes—the poetry of homely English scenery—in which he is without a rival. His handling is, however, very loose, his sense of form deficient, and his drawing often indifferent; but he was an admirable colourist, and threw around almost everything he touched an indescribable charm. Richard Wilson (b. 1713, d. 1782) learned landscape painting in Italy, and aimed at a more "classic" style. He wanted many of the qualities which are required in the painter of landscapes of the class to which his belong, but he had a true painter's feeling, and produced many admirable works. George Romney (b. 1734, d. 1802) was the avowed rival of Reynolds in portrait, and he painted some historical pictures. Benjamin West (b. 1738, d. 1820), who succeeded Reynolds as president of the Royal Academy, was a native of Philadelphia, then a British colony, but, after studying some time in Italy, settled while still young in England, and enjoyed until the Regency the post of painter in ordinary to the king. West's was a fair representative of the cold academic style of historical painting then current; and, though there was more of vigour in the historical pictures of James Barry (b. 1741, d. 1806), there was no more real truth or greatness. Henry Fuseli (b. 1741, d. 1825) was by birth a Swiss, but resided in this country the larger part of his life, and was professor of painting in the Royal Academy; his mannerism and strange extravagance of conception and expression are notorious. John Opie (b. 1767, d. 1807), James Northcote (b. 1746, d. 1831), and John Singleton Copley (b. 1737, d. 1815), were among the other most prominent contemporary painters.

Succeeding these, and forming the connecting links between the painters of the time of Reynolds and those of our own day, are some artists whom we must be content to mention, referring for further information to the names in the BIOGRAPHICAL DIVISION. At the head of those we may place West's successor in the academic chair, Sir Thomas Lawrence (b. 1769, d. 1830), the most popular, though not the greatest of English portrait painters. Thomas Stothard (b. 1755, d. 1834), had a singularly graceful fancy, but is seen to most advantage in the small vignette engravings from his designs. Sir David Wilkie (b. 1785, d. 1841) in his earlier works showed inimitable skill as a painter of scenes of domestic life. William Etty (b. 1787, d. 1849) was a powerful colourist, and in his own peculiar line, though that line was an eminently conventional one, he was doubtless a master. Joseph Mallard William Turner (b. 1775, d. 1851), the most original, the most imaginative, and the most comprehensive of landscape painters, belongs to too recent a date for us to enter upon his merits or shortcomings here; nor is it necessary to do so, as he is spoken of at length in the BIOGRAPHICAL DIVISION. John Constable (b. 1776, d. 1837); Sir Augustus Wall Calcott (b. 1779, d. 1844); Benjamin Robert Haydon (b. 1786, d. 1846); William Collins (b. 1787, d. 1847); Charles Robert Leslie (b. 1794, d. 1859), and many more, might be quoted as illustrative of the variety, tendency, and character of English painting in the first half of the present century. But to do so without more space than we have now left, would answer no useful purpose. We must not, however, conclude without reference to the rise and growth of that peculiarly English branch of the art, water-colour painting. Of course, in speaking of it as an English art, it is not meant to be implied that there was anything new in the practice of employing water as the vehicle, or paper as the material on which the colours are laid. But the adoption of this distinct branch of art, and its special application, are due to our countrymen; and by them water-colour painting has been more practised, and carried farther, than by the painters of any other country. The founder of the English school of water-colour painting was Paul Sandby (b. 1725, d. 1809), an artist of versatile talents and great taste. Those to whom its extension is primarily due were John Cozens (d. 1794); Thomas Girtin (b. 1775, d. 1802), the friend and fellow-student of Turner, and Turner himself. Luke Clennell (b. 1781, d. 1839); Samuel Prout (b. 1783, d. 1852); David Cox and others, whose names will recur to the reader, aided materially in raising the art to its present high standing.

PAINTING, ENAMEL. [ENAMEL.]

PAINTING, HOUSE, is the art of painting the interior and exterior of dwellings and other buildings with a composition which shall preserve from decay, please the eye, and render the surfaces to which it is applied less liable to soil and easier to be cleaned. It is executed either in oil or distemper.

Oil Painting.—The principal tools employed are brushes made of hogs' bristles for large surfaces, and sash-tools made of finer hair for small work, as mouldings, window-bars, &c. After being used, they are kept in water to prevent their getting hard.

Concerning the pigments employed, white lead is used for white colour; it is also the basis of all ordinary colours. The colouring substances (*stainers*) in general use are earths, umber, ochre, Siena, Venetian red, purple, brown, &c.; the first three are sometimes burnt, a process which reddens and darkens them. Metallic compounds are red lead, vermilion, Prussian blue, chrome yellow, verdigris, Brunswick green, verditer, &c. Animal and vegetable colours are lakes, indigo, ivory black, and lampblack. All these require to be ground very fine in oil. This tedious and unwholesome process was formerly performed by hand, and by painters for their own use; but now the manufacturing chemists are enabled, by the application of machinery, to supply the articles cheaper than they can be prepared at home; and the painter, being relieved from this troublesome part of his business, will, if he aim at excellence in his profession, turn his attention to the higher branches of his art, and study the laws by which colours are related to each other, so as to be able to harmonise or contrast them as occasion may require.

The liquids in use are linseed oil (sometimes boiled with litharge to render it quickly-drying, and hence called *boiled oil*), and oil or spirits of turpentine, called *turps*. These are combined for use in various proportions according to circumstances. When the paint is required to bear a gloss, or is intended for outside work, most oil is used; and for black, chocolate colour, green, &c., outside, boiled oil alone, or with a very little turps, is best. For flatting, which has no gloss, turps alone is requisite. To all paint a little sugar of lead, or litharge (*dryers*) is added when required to dry quickly. It is important that all surfaces intended to be painted should be thoroughly dry, otherwise the paint will be liable to peel off.

With respect to mixing, the workman takes as much white lead as experience tells him is requisite, and a little oil or turps; and after these are mixed by stirring with a stiff knife, he adds dryers and a portion of one or more of the *stainers* above mentioned, according to the tint which he wishes to produce. After reducing the mass to the consistence of cream by the addition of turps or oil, the whole should be strained through a piece of canvas or muslin, when it is ready for use, and is termed by the workmen *colour*.

For the best work, the knots of yellow deal should be cut out to the depth of a quarter of an inch by the joiner, while the work is on the bench, and pieces of the same wood inserted in their places and glued in hand-tight only, for if compressed by a blow with a hammer they will afterwards swell and spoil the surface. For general purposes the knots are painted with red lead and size. When this is dry, they are smoothed with glass-paper, and the work is ready for *priming*, which is composed of red and white lead ground in and mixed with linseed oil only. When dry, the work is again rubbed down with glass-paper or pumice-stone, and all nail-holes, &c., are stopped with putty. The following coats contain about as much oil as turps, and are termed *second colour*, *third colour*, &c. The last coat previous to the finishing one is in all cases termed the *ground*, and is nearly the colour of the intended finish: except for black, green, and some other coarse dark colours, for which the ground is lead-colour, composed of white and black mixed together.

The repainting of old work is the same as new, with the omission of the knotting and priming.

Stone-work, stucco, &c., are treated the same as wood. It is the general practice to repeat the coats, allowing sufficient time between each to dry, till the work ceases to absorb, which is known by the absence of dull spots and patches. It is also the practice to omit turps in mixing *colour* for work which is expected to absorb much. As to *graining*, the methods, tools, and materials adopted in this art vary with almost every workman, and it would be useless to attempt to describe in writing the processes which are so dependent on the artist's taste. It may suffice to state that the work having received a ground in oil of the predominating colour of the material to be imitated, the grain of wood is generally represented by semi-transparent colours mixed in beer. The subsequent varnishing fixes the colours, imparts a gloss, and defends the work from the weather.

Distemper Painting.—The brushes for large surfaces differ from those used in oil: they are wider and flatter, and are termed distemper-brushes; but the tools for small work are similar. Whiting takes the same place in this branch that white lead holds in oil; the colouring substances are similar, but ground in water; and the fluids are water and melted size.

The whiting having been reduced to a stiff paste with water in which alum has been dissolved, the colouring matter is added, and the whole thinned with warm size. It must then stand till it gets cold, and it is not fit for use unless it *chills*, or forms a slight jelly. It is best to strain it after it has *chilled*, as the colouring substances will sometimes sink. Before applying this, the work must be cleaned; for if there remains any substance which the fresh applied colour will soften and mix with, the work will not present a uniform appearance, but will be cloudy. The best work is painted first in oil, then flatted, and finished in distemper; but seldom more than one coat of distemper can be applied with advantage, for which reason care should be taken to cover every part equally, and particularly that the brush touch no part that is once dry; for this last reason several men are employed together, that the whole of any surface (as a ceiling) may be covered before any part has time to dry.

It is a generally received opinion among painters that white lead is the best material for painting work of all descriptions, with a view to its preservation, and they affirm that black paint is useless in that respect. Now, presuming that the durability of paint depends on the insolubility of the materials used in its composition, we might infer that black, which is composed of one of the most imperishable bodies known, namely carbon, in the state of lampblack, is more durable than white, which is made of carbonate of lead, a substance slightly soluble in water: and the following facts confirm this. To be able to judge fairly, we must have black and white of the same age equally exposed, and on the same material. These conditions are all fulfilled on finger-posts and other public notices exposed by the highways and on wooden grave rails in country churchyards, which are almost invariably painted and written either black and white or white and black. Those with black grounds and white letters may often be seen with merely the illegible remains of the inscriptions while the ground is quite perfect. But the black writing frequently remains not merely till the white ground is washed away, but often till the surface of the wood, except where it is occupied by the letters, is decomposed to the depth of more than a sixteenth of an inch, actually leaving the inscription in relief.

A more important circumstance connected with the use of white lead, however, is the extremely deleterious nature of this substance. House painters are much affected in their health in consequence. Zinc white has been introduced, and largely recommended, as a substitute for white lead; but the latter substance seems to possess qualities which enable it to beat down all opposition. Kuhlmann has recommended the adoption of sulphate of barytes. He declares that it is better than either white lead or oxide of zinc, more durable, and less injurious. It may be made either into dry cakes like white lead, or still better as a paste. Kuhlmann communicated a paper on this subject to the Academy of Sciences, at Paris, in 1858.

A patent process has been adopted for producing plain white polished surfaces in house painting. Carbonate of lead or zinc white is ground up with turpentine, partially dried, and mixed with copal body varnish; this paint is laid on, in many successive coatings, increasing the proportion of varnish at each stage. When dry, the surface is rubbed smooth with pumice dust or rotten stone, and polished with the hand. A kind of decorative painting is thus managed. Scrolls, flowers, or other devices are cut out of paper, and pinned to the wall or other surface; the surface is stippled with any suitable paint to produce a dead ground; when the stippling is dry, the paper is removed, and the ornament is left in high and light relief. In another method, the device is painted with a solution of sugar, starch, gelatine, and gum; the whole surface is then stippled over; and when dry, the stipple is washed off from the gelatinised surface.

Concerning painter's colours, it may here be stated that a manufactory was established at Battersea a few years ago, for making such colours by galvanic agency. During galvanic action, chemical decomposition always takes place in the cells; and by a careful choice of the liquids employed, sedimentary deposits of mineral colouring substances may be obtained. Practically, very brilliant colours were obtained, and sold in cakes; but the profits were not sufficient to render the speculation a permanent one. Another adventure has been that of obtaining a base for pigments from serpentine and other rocks containing silicates of magnesia and iron, by the action of certain acids; the bases thus obtained are mostly yellow, blue, and green. For the most part, however, painters are supplied with colours prepared by methods long practised.

The extent of this trade may in some degree be shown by the fact that painter's colours to the value of nearly half a million sterling are yearly exported from this country.

PALÆOGRAPHY (from *παλαιός, old*, and *γραφή, writing*), comprehends the study of ancient writing from the earliest periods until the invention of printing in the 15th century, or rather until that art became common at the commencement of the 16th.

The earliest specimens of writing occur upon stone, metals, wood, baked clay, wax, linen, the bark and leaves of trees, and the prepared skins of quadrupeds, goats, sheep, and calves. Writings upon the first named substances come more properly under the title of INSCRIPTIONS; those upon the bark of trees are fully treated of under the article PAPYRUS; it is therefore to some account of the principal characteristics of vellum or parchment manuscripts that the present notice is devoted.

In the earliest centuries we find much importance attached to the correct transcription of the works both of profane and theological authors, and as early as the 5th century, if not earlier, schools or associations of *scribes* were formed; who worked under definite and stringent rules. To a female scribe in one of these schools at Alexandria we are indebted for the famous copy of the Scriptures known as the 'Codex Alexandrinus,' written at the commencement of the 5th century, and now preserved in the British Museum. So great was the care taken to have correct copies of important works, that Jerome informs us that Pamphilus, the martyr, transcribed the works of Origen with his own hand; while distinguished men like Ambrose and Alcuin did not disdain the duty of comparing and revising the transcripts executed by the professional scribes. Baluzius cites decrees of the chapters against careless and bad copying, or transcriptions from vicious texts. In all the principal monasteries was a *scriptorium*, or writing-room, in which the *scriba, scriptor*, or scribe, could pursue his work in quiet, generally assisted by a *dictator*, who read aloud the text to be copied, the transcript was then gone over by a corrector, and afterwards handed over to the *miniator*, who added the ornamental capitals and artistic designs.

The word *parchment* is supposed to be derived from Pergamus, a city of Asia, in which the skins of sheep were largely prepared for manuscript purposes. *Vellum, velin*, prepared from the skin of the calf, *vitulus, veau*, from which it takes its name. The extreme whiteness and fineness of vellum may be taken as a sure sign of great antiquity. The finest vellum manuscripts are all prior to the 8th century.

Although a small cursive handwriting is occasionally met with even as far back as the 4th and 5th centuries, it was not until the close of the 8th that the *minuscule* writing became general. The broad capital letter in which the words are unbroken, and which has been designated as the *rustic*, is the prevailing character in manuscripts of the 4th and 5th centuries. The Vatican Virgil of the 4th century is a magnificent specimen of this style. The uncial and semi-uncial prevailed from the 6th to the 8th century. In the latter century fine minuscule Roman writing was not uncommon, and a fine example of this exists in the manuscript known as the Psalter of Charlemagne, in the Imperial Library at Vienna. Minuscule became general in Latin MSS. of the 9th, and Greek MSS. of the 10th century. The Latin MSS. of the 9th century are comparatively rare. They are for the most part written on fine thin vellum, in a small and very graceful character: the letters rather slanting to the right-hand. The manuscripts of the 10th century are more numerous than those of the preceding century, the letters are more upright, rounder, and fuller in shape, the vellum is commonly thicker and firmer. A magnificent specimen of the style of the 10th century, in the hand-writing of the famous St. Dunstan, abbot of Glastonbury, is preserved in the British Museum. It records a grant by King Eadred of the monastery of Reculver to the church of Canterbury, in the year 949. One is at first struck by observing that no trace of the ignorance which at this time darkened Europe, can be discovered in the numerous and exquisitely finished manuscripts of this century. But the fact may be partly accounted for by remembering the enormous dotations made to the religious orders, and their prosperity, in consequence of that very belief in the approaching end of the world, which degraded general society by the neglect of temporal interests to which it led. In the 11th century, owing probably to the general destitution, parchment was extremely rare, and it was in this century that the practice seems to have been most general of erasing ancient and so-called profane manuscripts in order to transcribe recent theological treatises upon the vellum thus acquired.

To manuscripts thus erased and again written upon, the name has been given of PALIMPSESTS, and to this word we refer the reader for a fuller description of such manuscripts. The handwriting of the 11th century bears a striking general resemblance to that of the 9th, the characters are small and closely written, and have a considerable slope. It seems probable that the small size of the writing may be in part accounted for by the difficulty of procuring parchment. The writing of the early part of the 12th century is not unlike that of the 10th, with the exception of the illuminated capitals, the peculiarities of which are described further on. The letters, however, particularly in English manuscripts, are larger and thicker. The vellum is mostly stout, and not so white. At the close of the century the beautiful and clear Roman writing was gradually becoming superseded by the introduction of an angular character, to which the term of modern Gothic has been applied. In the 13th century this Gothic character became universal. Even the round *o* was transformed into an elongated hexagonal. Abbreviations, hitherto rare and simple, became in this century numerous and abstruse. In addition to certain strongly defined peculiarities in illumination, of which we shall presently speak, the number and general use of abbreviations is, indeed, the most prominent palæographical distinction of the 13th century. In the 14th, the Gothic character still maintained its ascendancy; the letters, however, are generally broader and more open, and the abbreviations not quite so numerous as in the previous century. A great change is perceptible in the writing of the 15th century. Although still Gothic, it wants the massive and compact appearance of the two preceding centuries: the character is slighter and more open, and the heads and tails of the letters are thinner, weaker, and bended. Of the manuscripts of the 16th century it is almost unnecessary to speak. Owing to the introduction of printing, manuscripts had ceased to be written for the purposes of study, although occasionally, as well as in the two following centuries, executed as specimens of art or luxury. It should be remarked that the preceding sketch is confined to an attempt at delineating the appearance of the set hands of the various centuries. The cursive and epistolary styles are too capricious to be understood otherwise than by long and intimate acquaintance with the originals.

A method of distinguishing and deciding upon the various ages of MSS.—more easily acquired from description than the comparatively slight distinctions which mark the age of written documents, and which can only be acquired by careful study of originals—is afforded by the strong characteristic features displayed in the coloured and illuminated initial letters and ornaments so frequently found in MSS.

The first attempt at ornamentation seems to have been the use of *minium* or vermilion in marking the titles or commencement of manuscripts; and this is the origin of our word *miniature*, which first signified the rubricated letters, afterwards comprehended the whole separate branch of ornamentation of MSS., and now exclusively signifies a picture painted in the style necessarily adopted by the artists who worked on the small sheets of vellum, of which early books were composed.

In the most ancient volumes now remaining red letters were used for the purpose before mentioned, and in some cases also to mark words of particular importance—an example of which is afforded by the Alexandrian MS., and others of the 4th and 5th centuries. In these and the succeeding centuries the custom of writing in burnished gold and silver was extensively employed, remnants and records of which have descended to our times. The most ancient example is perhaps the *Codex Argenteus* of Ulphilas, written on purple vellum, at the close of the 4th century. The use of vellum stained of a rose or violet colour is peculiar to this early period, and lasted till the end of the 7th century—the efforts of the 8th and 9th centuries losing all the brilliancy and purity of the earlier specimens. In England purple MSS. were only introduced at the close of the 7th century.

Manuscripts written in letters of gold or silver on white vellum are chiefly confined to the 8th, 9th, and 10th centuries. Instances of its use in later times are on record, and in the 14th century instances are not seldom found; but at this period it can hardly be termed writing, being rather a laborious process of minute gilding.

On the works of the Byzantine schools, it would be beyond our present purpose to enlarge, as with slight variations, century after century, they followed old traditionary types. The influence, however, of Byzantine art has left strong and unmistakeable traces in all the works of the western nations, with which it is our present purpose to deal.

To the remotest of these nations the praise is due of having invented and developed an independent school of ornamentation, and one destined to become a formidable rival to the traditionary splendours of Eastern art. In Ireland, as far back as the 5th century, a style of art had been practised, which in the succeeding centuries attained a perfection almost incredible. In nearly complete isolation from the rest of the civilised world, having few opportunities of seeing and admiring the works of the great Greek artists, their method of ornamentation exhibits no artistic power in the higher sense of the word, but is remarkable for a fine harmony of colour, and a precision of technical execution little short of miraculous. The principal features of the style are an intricate and tortuous interlacing of narrow threads or ribands generally in symmetrical patterns, sometimes filling up a letter, sometimes extending over a whole page; now the introduction of a number of circular ornaments, now filled by marvellously delicate spiral lines proceeding from the centre, now by bolder wheel-like patterns of endless variety of design—to these may be added the use of numbers of birds and animals coiled up in endless and seemingly inextricable confusion, sometimes, as in the case of the Book of Kells, varied by the introduction of the human figure, and patterns formed of diagonal and straight lines, generally in squares or compartments, the idea of which some writers assert to have sprung from the remembrance of tesselated pavement.

Of manuscripts of this style the Book of Kells of the 7th century, now at Trinity College, Dublin, is the most important.

This peculiar method of design was early introduced into England by Irish missionaries, and a splendid specimen of its adaptation is preserved in the celebrated Durham Book, in the British Museum—which was executed at Lindisfarne at the commencement of the 8th century. In this may be traced at once a stronger influence of the Byzantine types; and though a most superb specimen of writing and decoration, it does not exhibit the same originality or fertility of imagination as the works of the Irish school. From England the new style passed quickly to the continent, and was soon adopted and largely used by the illuminators, and it is curious to notice in the manuscripts of the succeeding centuries, prolific in works of splendour and elegance, the admixture of the Celtic ornament with the remains of classic design.

A change, however, nearly as important, though not perhaps so original in conception as this of which we have treated, was introduced by the English illuminators of the 10th century. This consisted in the introduction of foliage. At first it was of an entirely rudimentary character, and exhibited none of the botanical skill or study of nature, so closely observed in later times. It was, in fact, the reflex of the bold and original ornamentation introduced by the architects of the period, and the styles of this and the two succeeding centuries were little more than adaptations to book decoration of the ornaments and mouldings of the great architectural works of the time. It was, however, a great advance on the semi-barbaric style of the Irish, or effete classicism of the continental works. Stalkless, thick-looking leaves spring from between and twine round the parallel bars of gold in borders or the curves of letters, coloured in every variety of tint, and mixing now and then with the interlacings and heads of animals, still retained from Hibernian designs. A most magnificent specimen of this peculiar style, to which on the continent the exclusive title of "*opus Anglicum*" was given, is the Benedictional of St. Ethelwold, now in the possession of the Duke of Devonshire. This manuscript was executed at Winchester (the great school of the arts in England) at the close of the 10th century. In the succeeding century the style was more developed, the forms and curves of the leaves were more freely drawn, with corresponding increase of knowledge and power in the figures and animals now freely introduced again, evident reproductions of the fantastic carvings of the architecture of the period. In the 12th century this foliation culminated in most luxuriant and fantastic conventionalism, and works of this period are perhaps as magnificent and splendid as any that any age has produced. The initial letters are very prominent and elaborate, and exhibit great elegance in the curves of the branches which support their luxuriant foliage. A very great advance too is visible in the drawing of the figures, and particularly of the drapery, which instead of the fluttering and restless timidity of the preceding centuries, falls in broadly marked masses, and indicates form in a highly artistic manner. These remarks chiefly apply to art in England, as there design was more original and exhibited less of the influence of the decadence of Byzantine art.

But a re-action from the strained conventionalism of this took place in the succeeding century, and men's minds were directed to a more careful study of nature for their guide; and to this study of nature, the groundwork of all that is beautiful and true, may be traced the wonderful advance visible in all the works of art of this great epoch, and of which its architecture exhibits such glorious memorials. Heretofore, the artists had drawn their foliage without study of the real nature of its growth, now they let themselves be guided by nature alone, and began the new era by using as the basis of their ornament the leaf springing from the bud. This is the principal feature in all the initial letters of this period, which now also become especially attractive from the use of burnished gold, scarlet, and blue. In the miniatures of manuscripts gold backgrounds are constantly employed, more especially in French work, the English artists confining themselves to a lower tone of colour, and employing backgrounds of colour relieved by small powdered patterns, differing considerably from the style we notice in the next century. In the 14th century the gold and plain back-grounds give way to rich patterns of diaper and chequer work, and the heavy mass of burnished gold is divided into minute patterns or entirely superseded by variegated colour. In this century too the bud expands into the leaf and the ornamentation of a letter, instead of being confined to one or two sprays of foliage, spreads out and encompasses the page in a glittering circle of golden leaflets, or by what we may term ornamental brackets, less massive but more elegant than the ornament of the 12th century; and rendering this the most easily distinguished, as well as the most attractive of all the various styles of illumination. In the 15th century sprang forth the flower, and very beautiful though gaudy was the result; and at the same time too, the progress of the art of painting caused the illuminators to depart in their works from their hitherto strictly symbolic character, and to aim at the direct representation of nature. The introduction of backgrounds of pure landscape in the miniatures is as nearly as possible coincident with the commencement of the century, and from this time the pictorial representations completly supersede in importance the mere ornamental portion of an illuminated page. As a consequence, the ornamented borders became gradually used as a mere framework for the miniature; and the beautiful ornament of the 14th century, by the introduction first of diagonal bands of gold and other patterns behind its foliage, and afterwards of solid grounds of colour, was degraded in time to the gaudy and meretricious style of the 16th century. The illuminations of that period are chiefly known by the use of sprays of flowers and fruit on delicate scroll work, relieved from the solid border by exquisitely executed shading—the lights heightened with gold, and to ordinary eyes presenting an appearance more attractive than the works of any preceding century.

We cannot in the limited space of this article do more than hint at the importance of the study of costume of different periods, as furnishing another very strong corroborative test of the age of manuscripts in which illuminations occur; nor, interesting though it be, can we treat of the purely artistic portion of the subject, as our present object is solely the palæographic portion of the inquiry. We will, therefore, at once sum up briefly, and in a manner easily remembered, the great lines of demarcation which separate the different epochs. This we will do, taking the centuries in triplets.

Of the first three centuries we can say nothing. In the 4th, 5th, and 6th we find little ornamentation beyond the rubricated or gilded letters of the actual text. The 7th, 8th, and 9th, witnessed the perfection and adoption of the Hibernian style. The 10th, 11th, and 12th, the introduction and use of architectural forms. The 13th, 14th, and 15th, the growth of foliage under carefully studied natural laws; the 13th century being the age of the bud, the 14th of the leaf, the 15th of the flower; and in the miniatures, the 13th the age of gold, the 14th, of diaper, the 15th the commencement of realistic painting. Of the next century we need say little, as manuscripts formed no longer the bulk of literature, but were mere costly appendages of luxury and taste.

The broad outlines we have here given are of course open to many exceptions, as the artists of different countries worked under different influences; indeed, to Italian works they can hardly be said to apply at all, as that nation infused a new life of its own into the Byzantine style in a more gradual manner than the sudden and independent changes of the western nations.

Throughout the whole of the dark and middle ages the value attached to the possession of manuscripts, and the activity shown in multiplying them, are very remarkable. Silvestre tells us that long previous to the 12th century, the most active zeal was displayed in search after ancient texts, even of profane authors. "In the middle of the 9th, Lupus, abbot of Ferrières, earnestly requested from the Pope and the bishops of England and Ireland, the loan of manuscripts of ancient writers that copies might be made of them; and in 1040, Count Geoffrey of Anjou gave to the abbey of Notre Dame of Saintes, the tithe of the hides of the deer killed in his forests, to furnish a fund to bind the books of the monastery." (Silvestre, ed. Madden, ii. 311.) The same writer, *loc. cit.*, mentions also the veneration paid in the 15th century to the Florentine Pandects of the Laurentian library, a magnificent volume written in the 7th century, and esteemed the most valuable of the manuscripts of the Roman law. This manuscript was taken from Pisa by the Florentines in 1406, and after its deposition at Florence "was regarded with almost religious veneration, being shown only to the highest personages, with great ceremony, in the presence of the chief magistrate, accompanied by monks, bareheaded, and bearing lighted tapers."

The price of manuscripts in the middle ages is a subject full of interest, the data for determining which, although existing scattered throughout various manuscripts, has never been properly collected or discussed. A recent writer (Mr. Digby Wyatt, 'Art of Illuminating') furnishes "a most interesting contemporary illustration of the precise terms upon which noble patrons employed the best illuminators of the day (14th century)," in the shape of an extract from the fabric rolls of York Minster, 1346, in which a contract seems to have been entered into for writing a volume containing psalter, hymnal, and collectary, ornamented with illuminated letters in gold, azure, and vermilion, for about sixteen shillings. Such a price, however, far from indicating the cost of the works of the "best illuminators," could only have represented a manuscript of comparatively rough and coarse description. There is in the British Museum a 14th century bible, taken by the English at the battle of Poictiers, exactly ten years after the date of the contract quoted above. The volume is a large one, and contains a good many illuminated letters in addition to some miniatures and borders of a tolerably fair, although by no means superior kind. This volume, the spoil of war, William Montagu, earl of Salisbury, purchased at the time for one hundred marks (upwards of 62*l.*, representing about 360*l.* of our money), as a present to his countess, and it was arranged that at her death it should be sold by her executors for 40*l.* This is recorded in a contemporary entry at the commencement of the volume, so curious in its details that we give it entire: "Cest liure fust pris oue le Roy de Fraunce a la bataille de Peyters, et le bon Comte de Saresbirs William Montagu la achata pur cent mars et le dona a sa compaigne Elizabeth la bone Countesse qe dieux assoile. Et est continus de dedeius le Bible enter oue text et glose e le mestre de histoires, et incident tout en memes le volym. La quele lyure la dite Countesse assigna a ces executours de le vender pur xl liuers." Again, in the 15th century, a roughly executed volume of 219 leaves, now preserved in the British Museum, and containing the Book of Wisdom with gloss, the capitals in plain blue and red, is priced at lx shillings. A further insight into the price of such manuscripts is gained from the very curious memoranda occasionally met with of the price for which such books were pawned or set in pledge. There is a manuscript in the old royal collection, British Museum (7 E v), which was pawned by its possessor five different times, between the years 1483 and 1510, a fact showing not only the worth of manuscripts, but how readily a money value might be obtained for them. This manuscript is of the 14th century, roughly executed, and contains a treatise entitled 'Pupilla Oculi,' by John Borough, and a sacramentary. It will be seen from the entries, which we subjoin, that in 1483 he pawned it for 20*s.*; in 1485, for 16*s.*; 1488, for 26*s.* 8*d.*; in 1510, for 20*s.*, and again for 16*s.* 8*d.*, and it must be remembered that these sums cannot be supposed at the most to represent more than a moiety of the worth of the manuscript: "Cautio domini Johannis Corke, excepta in cista de Gylford, A.D. 1483, 5 die Maii, et jacet pro 20*s.* Renovatur cautio hec 24 Januarii, A.D. 1485, et jacet pro 16*s.* Cautio M. J. Corke, A.D. 1488, in cista de Wagon et Hosy, et habet unum supplementum, et est Albertus de Naturis 2°. fo. illorum, et jacet pro 26*s.* 8*d.* Renovatur hec cautio per manus Magistri Johannis Corke, A.D. 1510, 22 die mensis May, et nunc jacet pro 20*s.* Item eodem die renovatur per manus ejusdem magistri Corke et nunc jacet pro 16*s.* 8*d.*" These entries specifying the sums lent upon manuscripts, sometimes for the accommodation of the possessor, and sometimes apparently as security for safe return when borrowed for purposes of study or transcription, are highly curious.

PALÆSTRA (*παλαιστρα*), which properly means a school for wrestling (*παλαίειν*, "to wrestle," and *πάλη*, "wrestling"), was used in several different significations. The word first occurs in Herodotus (vi. 126, 128), who informs us that Clisthenes built at Sicyon a dromos and palæstra, both of which he calls by the general name of gymnasia. At Athens, however, it appears probable that the palæstræ and gymnasia were distinct places, and that the former were appropriated to the gymnastic exercises of the boys and youths (*παῖδες* and *μειράκια*), while the latter were intended for those of the men; it is certain, however, that the boys also exercised in the gymnasia. These palæstræ were called by the names either of their founders or of the teachers of the gymnastic exercises (*παιδοτρίβαι*). We accordingly read in Plato of the palæstra of Taureas, which appears to have been one of the most celebrated. (Plato, 'Charmid.,' c. i.; with Heindorf's 'Note.')

In most of the other cities of Greece the palæstra formed a part of the gymnasium. According to Müller ('Archäologie der Kunst,' § 292) it included the *στάδιον* (stadion); *ἐφηβεῖον* (ephebion, or exercise hall); *σφαιριστήριον* (sphæristerion, or hall for ball-play); *ἀποδυτήριον* (apodyterion, room for undressing); *ἐλαιοθέσιον*, or *ἀλειπτήριον* (elæothesion, aleipterion, room for anointing); *κονιστήριον* (konisterion, for rubbing with dust); *κολυμβήθρα* (columbethra, a swimming-bath); *ξυστοί* (xystoi, covered walks); *περιδρομίδές* (peridromides, open walks); in fact, every part of the gymnasium except the outer porticoes. It appears, however, more probable that the term palæstra was confined to the rooms which were appropriated to the exercises of the athletæ, who, it must be recollected, were persons who were especially trained for contending in the public games, and therefore needed a course of gymnastic exercises different from that which was usually pursued. That this view of the subject is correct, is shown by the statement of Pausanias, who informs us (vi 21, s. 2), that in the gymnasium at Olympia there were palæstræ for the athletæ, and also by that of Plutarch, who says ('Symp.,' ii., Probl. 4) "that the place in which all the athletæ exercise is called a palæstra."

Among the Romans the terms palæstra and gymnasium are used as synonymous. Thus Vitruvius gives a description (v. 11) of a Greek gymnasium under the name of palæstra. In the Greek cities in Sicily and Italy there also appears to have been no distinction in use between the two words (Cic. in 'Verr.,' ii. 14; Polyb., xv., p. 716, c.: Casaubon); whence the Romans probably came to use them in common. [GYMNASIUM.] (Krause, 'Gymnastik und Agonistik der Hellenen;' Becker, 'Charicles,' v. 1.)

PALANQUIN (sometimes written *Palankeen*, and *Palkee*), a kind of covered litter carried, by means of poles, upon the shoulders of men, which forms the principal vehicle for personal transport in Hindustan, and varieties of the vehicle are used in other eastern countries. In Hindustan the palanquin is described by Captain Basil Hall, in his 'Fragments of Voyages and Travels,' third series, vol ii. chap. vi., as about six feet long by two and a half feet wide, and provided with conveniences which enable it to serve at night-time for a bed, and in the day-time for a parlour. A pole is attached to each end of the palanquin, near the top, to carry it by. As the poles, which rest upon the shoulders of the bearers, are not elastic like those of a sedan-chair, Captain Hall states that a palanquin has not the same unpleasant motion as that vehicle; and Bishop Heber also, who gives an account of dâk travelling in the 'Narrative of a Journey through the Upper Provinces of India,' published after his death, observes that "the motion is neither violent nor unpleasant," but that, being incessant, it is impossible to draw in a palanquin, and not very convenient to read, excepting a large print. Only four bearers can, in an ordinary palanquin, place their shoulders beneath the poles, two at each end; but in passing over difficult ground two others will occasionally bear part of the weight by thrusting a bamboo under the body of the palanquin; and in travelling there are two or more sets of bearers, who relieve each other by turns. While walking or running with their load, the bearers, who form a peculiar class among the Hindus, keep up an incessant noise, sometimes like grunting or groaning, and sometimes approaching the character of a song, or of wild vociferation.

The mode of conveyance is undoubtedly ancient. A conveyance of this sort was used by the Egyptians, as is shown by a representation found at Beni Hassan. In western Asia they are usually carried by camels; and one of a similar character is borne by an elephant, but this is usually called a *howdah*.

PALATINE COUNTIES. Three of the English counties, Chester, Lancaster, and Durham are counties palatine, by prescription. The county of Pembroke, in Wales, was also a county palatine, till the statute 27 Henry VIII., c. 26. The archbishop of York, previously to the reign of Elizabeth, claimed to be a count palatine within his possessions of Hexham and Hexhamshire, in Northumberland, and is so termed in some ancient statutes; this was put an end to by the stat. 14 Eliz., c. 13.

Counts palatine are of feudal origin; and a reference to their history will clearly explain the meaning of the title, and many of the incidents of these territorial dignities. Selden says, "the name was received here doubtless out of the use of the empire of France, and in the like notions as it had in that use" ('Titles of Honour,' part ii.). In the court of the ancient kings of France, before the time of Charlemagne, there was a high judicial officer, called the Comes Palatii, a kind of master of the household, whose functions nearly resembled those of the Præfectus Prætorio in the elder empire. This officer had supreme judicial authority in all causes that came to the king's immediate audience. ('Tit. of Hon.,' part ii., chap. 33.) When the seat of empire was transferred to France, this title and office still continued, but the normal dignity, as well as a degree of jurisdiction and power analagous to those of the ancient functionary, were also given to a different class of persons. When the sovereign chose to confer a peculiar mark of distinction upon the holder of a certain fief or province, he expressly granted to him the right to exercise the same rank, power, and jurisdiction within his fief or province as the comes palatii exercised in the palace. Hence he also obtained the name of comes palatii or palatinus, and by virtue of this grant he enjoyed within his territory a supreme and peculiar jurisdiction, having royalties, or jura imperii, by which he was distinguished from the ordinary comes, who had only an inferior and dependent authority within his district or county. This was the origin of the distinction between the Pfalzgraf and the Graf in Germany, and between the count palatine and the ordinary count or earl in England. Selden says that he had not observed the word "palatine" thus used in England until about the reign of Henry II.

In conformity with this view, the counts palatine of England had jura regalia within their counties, subject only to the general superiority of the Crown sovereign; or, as Bracton expresses it (lib. iii. cap. 8), "regalem habent potestatem in omnibus, salvo dominio Domino Regi sicut principi." They had each a Chancery and Court of Common Pleas; they appointed their judges and magistrates and law officers; they pardoned treasons, murders, and felonies; all writs and judicial proceedings issued and were carried on in their names; and the king's writs were of no force within their counties. Many of these powers, such as the appointment of judges and magistrates and the privilege of pardoning, were abolished by the stat. 27 Henry VIII. c. 24, which also provided that all writs and process in counties palatine should from that time bear the king's name. The statute, however, expressly stipulates that writs shall be always witnessed in the name of the count palatine.

The county of Chester is a county palatine by prescription, being commonly supposed to have been first given with regal jurisdiction by William I. to Hugh d'Avranches. ('Tit. of Hon.,' part ii.) It was annexed to the crown, by letters patent, in the reign of Henry III., and since that time it has always given the title of Earl of Chester to the eldest son of the sovereign, being preserved in the crown as a county palatine when there is no Prince of Wales.

Lancaster appears to have been first made a county palatine by Edward III., who, in the twenty-fifth year of his reign, in his patent of creation of Henry, the first duke, granted him the dignity of a count palatine, and afterwards, in the fiftieth year of his reign, granted the same dignity by letters patent to his son John, Duke of Lancaster. Henry IV. was Duke of Lancaster, by inheritance from his father John of Gaunt, at the time of his usurpation; but he avoided the union of the duchy with the crown by procuring an act of parliament, which declared that the duchy of Lancaster should remain with him and his heirs for ever, in the same manner as if he had never been king of England. Upon the attainder of his grandson Henry VI., soon after the accession of Edward IV., the duchy became forfeited to the crown, and an act of parliament passed to incorporate the county palatine with the duchy of Lancaster, and to vest the whole in Edward IV. and his heirs, kings of England, for ever. Another act of parliament passed in the reign of Henry VII., confirming the duchy to the king and his heirs for ever; and from that time to the present it has continually been united to the crown.

Durham, like Chester, is a county palatine by prescription; but it is probable that the palatine jurisdiction did not exist long, if at all, before the Norman Conquest. (Surtee's 'History of Durham,' Introd., p. 15.) "There is colour to think," says Selden ('Tit. of Hon.,' part ii. c. 8), "that the palatine jurisdiction began then in Bishop Walcher, whom king William I. made both episcopum and dux provinciæ, that he might frenare rebellionem gentis gladio, et reformare mores eloquio, as William of Malmesbury says." Durham continued as a county palatine in the hands of a subject till 1836, the bishop being prince palatine, and possessing jura regalia. By stat. 6 & 7 Will. IV., c. 19, palatine jurisdiction was transferred to the crown, subject to certain restrictions which have been removed by later statutes.

PALI. [Sanscrit Language and Literature.]

PALIMPSEST (παλιμψήστος, from παλιν again, and ψάω to cleanse or rub) is a term applied to a manuscript, from which the original text has been erased, in order to make room for a second subject; a process which was accomplished by rubbing it with pumice-stone or other similar substances till the traces of the original writing disappeared, and then smoothing it down with a roller or polisher. That this practice was adopted by the ancients, appears from a passage in Cicero's letter to the jurisconsult Trebatius, where he praises his friend for having been so economical as to write on a palimpsest, but says that he should like to know what those things could have been which were considered of less importance than his letter. ('Ad Familiares,' vii. 18.) Palimpsests are also mentioned by Plutarch and Catullus, but these appear to have been rather leaves of books, so prepared that one writing could easily be expunged and another substituted, and were frequently used by authors for correcting their works, as is evident from the satire of Catullus:—

> "Puto esse ego illi millia aut decem aut plura
> Perscripta: nec sic, ut fit, in palimpsesto
> Relata; chartæ regiæ, novi libri,
> Novi umbilici, lora rubra, membrana
> Directa plumbo, et pumice omnia æquata."
>
> CARMEN, xxii., l. 5 *et seq.*

It was not, however, till the 9th or 10th century that this practice became at all general, and then it was more frequently resorted to by the Latins than the Greeks. In the 11th century it appears to have been at its height. In the 13th and 14th centuries edicts forbidding it were issued in Germany; and it had not entirely ceased in the 15th century: as Knittel, in his account of the palimpsest manuscripts in the Augustan library at Wolfenbuttel, tells us that in the early times of the art printed books were sometimes worked off on vellum from which ancient writings had been erased, and instances particularly an edition of the Clementine Constitutions, printed by Nicolas Janson in 1476 upon parchment, which had undergone this process of obliteration to prepare it for the purpose.

The earliest observations on palimpsest manuscripts were made in France, in 1692, by M. Boivin, of the Bibliothèque du Roi, who discovered beneath the Greek text of St. Ephrem, written in the 14th century, a portion of the Greek Bible, in uncial letters of the 6th century. This was followed, in 1755, by a similar discovery made by F. A. Knittel in the Augustan library at Wolfenbüttel, of a palimpsest manuscript of the Origines of Isidorus, under which was a translation of the Epistle to the Romans, by Ulphilas, bishop of Gothland, who in the 4th century was known to have translated the whole of the Scriptures into the language of that country, and to have invented a new character, consisting of letters borrowed chiefly from the Greek for that purpose, but of whose labours only the four Gospels were previously known to exist in the *Codex Argenteus* at Upsala. In 1762, Knittel published, in 4to, the greater portion of the missing volume, which, although not identical with the *Codex Argenteus*, as originally supposed, proved to be a portion of a similar manuscript.

By far the greatest discoveries in the field of palimpsest manuscripts were, however, made by Cardinal Mai. In his researches in the Ambrosian library at Milan, of which he was keeper, he discovered several fragments of Cicero's orations; these comprised the orations against Clodius and Curio, that 'De Ære alieno Milonis,' not previously known, and the oration 'De Rege Ptolemæo.' These treasures had lain concealed for centuries under a Latin translation of the Acts of the Council of Chalcedon, and were adjudged by the discoverer to belong to the 4th century. In another manuscript he detected several fragments of the orations of Symmachus, who had previously been known only from his epistles; and the whole of the comedies of Plautus, including a fragment of the 'Vidularia,' a lost comedy, of which all that previously existed were twenty lines, preserved by Priscian and Nonius.

Being promoted to the librarianship of the Vatican, he discovered in that library the treatise of Cicero, 'De Republicâ,' of which nothing had been known, in modern times, beyond the fragments preserved in the writings of Macrobius, Lactantius, Augustin, Nonius, and others. This priceless manuscript came from the celebrated Abbey of St. Columbanus, in Bobio, in the Milanese territory, having been purchased by Pius V., who appears to have been acquainted with its value as a palimpsest; yet no attempt was made to decipher it till two and a half centuries later, when Cardinal Mai brought out his famous edition at Rome in 1821. This manuscript, which contains 300 pages, is in double columns, each consisting of fifteen lines. The writing is in fine, large, Roman uncials, the words not divided. It is clearly one of the earliest palimpsest MSS. yet discovered, and is referred by Cardinal Mai to the 2nd or 3rd century of our era. Above the treatise was a copy of St. Augustine's Commentary on the Psalms, in a handwriting earlier than that of the 10th century.

These researches of Cardinal Mai gave a new zest to the study of palimpsest writings, and shortly after Niebuhr examined several of the manuscripts in the library of the chapter at Verona, one of which was discovered by him to contain a palimpsest of some ancient jurisconsult, which he suggested to be the Institutions of Gaius, a conjecture which was verified by the Berlin Academy of Sciences, under whose auspices the first edition of this work appeared in 1820, scarcely a ninth of the whole book having been found illegible. This palimpsest is more particularly interesting in a palæographical point of view from having been twice rescribed. The uppermost of the three writings, comprising 26 Epistles of St. Jerome, is in the uncial character. As to the age of the original manuscript, Niebuhr, who is supported by Kopp, conjectures it to be anterior to the time of Justinian.

The greater number of the very ancient palimpsest manuscripts which are preserved in the Vatican, and in the Ambrosian Library at Milan, as well as those at Turin, in which remains of the classical authors have been found, were originally brought from the monastery of St. Columbanus at Bobio, founded by the famous Irish saint, and are inscribed 'Liber Sancti Columbani de Bobio.' Numerous examinations have lately been made of the Latin and Greek manuscripts at Paris, and many palimpsests have been discovered, but none containing texts of importance.

In the British Museum is a palimpsest of the Iliad, written on vellum, in fine, square, Greek uncials with accents and breathings, not later than the 6th century; it contains about 4000 lines, the uppermost text being Syriac, probably of the 9th century.

To another Syriac manuscript contained in the same library, we likewise owe the important addition to classical literature of portions of the annals of Gaius Granius Licinianus. In the year 1847, the authorities of the British Museum purchased from M. Pacho a number of Syriac manuscripts, and fragments of manuscripts, which had formerly belonged to the monastery of *S. Maria Deipara*, in Nitria (the valley of the lake of Nitron). Amongst these was one containing fragments of sermons of St. Chrysostom, written in Syriac, probably about the 9th century, or rather later. On examination, several leaves of this manuscript proved to be palimpsest; and closer research revealed the fact, that prior to these Syriac sermons, the vellum had already received two earlier texts. The most ancient of these texts written in an uncial character, probably of the 4th century, was found to contain portions of the Annals of Licinianus. These were edited in 1857 by Dr. Karl Pertz, under the title, 'Gai Grani Liciniani Annalium quæ supersunt, ex codice ter scripto Musei Britannici Londinensis.' In the following year the text, as furnished by Pertz, was more carefully re-edited by seven scholars of the University of Bonn, under the title, 'Grani Liciniani quæ supersunt emendatiora edidit Philologorum Bonnensium Heptas.' The later of the two texts appears to be a grammatical treatise written in a cursive hand of the 7th or 8th century. It is much to be regretted that the chemical agency applied to this palimpsest for the purpose of rendering it more easily read, though successful for the moment, has ultimately caused many of the originally faint traces of letters to become absolutely illegible. This should act as a warning of the extreme caution necessary in employing powerful re agents in similar cases.

PALISADES are strong palings placed generally 6 or 9 inches apart, and pointed at their top to act as an obstacle in fortifications. They are generally placed in field fortifications at the bottom of the counterscarp of the ditch, or else projecting nearly horizontally from the top of the escarp. In permanent fortification the interior slope of the glacis and the traverses of the covered way are furnished with palisades to assist in the defence; here the openings between the timbers allow the defenders to fire through them. They are secured together about their middle by a horizontal timber termed a ribbon, and also at their lower ends by a strong beam sunk 3 or 4 feet in the ground. In permanent works the timbers are generally about 4 or 6 inches square, or triangular by cutting these across the diagonal. But in field-works the rough stems of young trees are often used.

PALL, or PALLIUM, a cloak or covering; more especially used for the ornamental article of dress granted by the pope to patriarchs and archbishops: it is made of white wool, in the form of a band three fingers broad, to surround the shoulders, having pendants a span in length before and behind, the ends ornamented with red crosses. The origin of the pall is obscure; but its use is of high antiquity. Tertullian, who lived at the beginning of the 3rd century, wrote a treatise 'De Pallio.'

Sleidan, in his commentaries 'De Statu Religionis et Reipublicæ, Carlo V., Cæsare,' 4to, Argent, 1555, lib. xiii., p. 210, describes the ceremony of making the pall. The price at which they are purchased from the pope, he adds, is considerable; nor is it lawful for an archbishop to use his predecessor's pall. If by exchange, or in any other way, a patriarch or metropolitan is removed to another church, although he had purchased a pallium before, he must still be at the charge of a new one. Before the receipt of his pall an archbishop cannot perform the functions of his office, even if he has been translated, nor can the archiepiscopal cross be borne before him.

The original grant of the pall from Pope Julius II. to Archbishop Warham is still preserved among the Cottonian manuscripts in the British Museum. The following is the form:—"Ad honorem dei omnipotentis, et beatæ Mariæ Virginis, et beatorum Apostolorum Petri et Pauli ac domini nostri Julii, pp. ij. et sanctæ Romanæ Ecclesiæ, necnon Cantuariensis Ecclesiæ tibi commissæ, tradimus tibi Pallium de corpore beati Petri sumptum, plenitudinis videlicet pontificalis Officii, ut utaris eo infra Ecclesiam tuam certis diebus qui exprimuntur in privilegiis ei ab apostolica Sede concessis. Aloisius."

In the east the pall is called *omophorion* (ὠμοφόριον), and has been used at least since the time of Chrysostom, who was charged with accusing three deacons of taking his omophorion. (Photii, 'Bibliotheca,' edit. Par. 1611, p. 55.) It is worn by all the Eastern bishops above the phenolion, or vestment, during the eucharist; and, as used by them, resembles the ancient pallium much more nearly than that worn by Western metropolitans, approaching nearer to the shape of a cope.

In England the term pall is applied to the covering thrown over the coffin at a funeral; and our poets have used it as synonymous with a mantle or cloak of a stately character. Milton says,—

"Let gorgeous tragedy
In scepter'd pall come sweeping by."

(Du Cange, *Glossar.*, v. 'Pallium;' Picart's *Religious Ceremonies*; Palmer, *Origines Liturgicæ*, 8vo., Oxf., 1832, pp. 317, 318.)

PALLADAMINE. [PALLADIUM.]

PALLADIUM (Pd). A rare metal, chiefly occurring as an alloy with platinum and iridium, but sometimes in the pure state. For its natural history, see PLATINUM, in NAT. HIST. DIV. To isolate it, the platinum ore is dissolved in nitrohydrochloric acid, chloride of ammonium is added to precipitate the platinum, and the palladium is then thrown down as cyanide from the filtered solution by the addition of cyanide of mercury: the white flocculent cyanide of palladium is then heated with sulphur to expel cyanogen, and the sulphur finally got rid of by well roasting. Brazilian gold usually contains five or six per cent. of palladium, and is therefore another source of this metal.

Palladium is hard, white, ductile, and tenacious. It readily fuses before the oxhdydrogen blowpipe, and is volatile at the temperature of melted iridium. It is more oxidisable than silver, but is very slowly tarnished in the air. Its density is 11·8. It dissolves in zinc, but does not combine with that metal. It forms a crystalline alloy with tin, containing three equivalents of palladium to two of tin, and the resulting compound very much resembles the corresponding alloys of silver and copper with tin. Palladium is soluble in aqua regia, or in hot nitric acid, but is not easily acted upon by the other acids. It is readily distinguished from platinum, which it somewhat resembles in appearance, by being stained brown by a drop of solution of iodine.

The equivalent of palladium is 53·24.

Palladium and *oxygen* form two well-defined compounds, viz.:—

1. Protoxide of palladium	PdO
2. Binoxide of palladium	PdO_2

According to Rané a *suboxide* (Pd_2O) is produced on heating the hydrated protoxide to incipient redness.

1. *Protoxide of palladium* is obtained as a black powder on heating nitrate of palladium to low redness. It has somewhat the appearance of black oxide of manganese, and loses its oxygen when heated to whiteness. It is precipitated as a dark brown *hydrate* (PdO, HO), on adding carbonate of potash or soda to a solution of a protosalt of palladium. The hydrate is soluble in caustic potash, and loses its water when moderately heated.

2. *Binoxide of palladium* is obtained as a yellowish brown hydrate (PdO_2, HO) on adding solution of caustic potash, or carbonate of potash, to the solid double bichloride of potassium and palladium. It is reduced to the anhydrous state by mere boiling with water and is then black.

Carbide of palladium. Palladium is very apt to absorb carbon when heated in contact with that substance, and is thereby rendered exceedingly brittle.

Sulphide of palladium (PdS). A blackish brown precipitate, formed on passing sulphuretted hydrogen through a solution of a protosalt of palladium. The metal itself also when heated with sulphur combines with incandescence, and forms a fusible gray lustrous mass.

Iodide of palladium (PdI) is a black precipitate formed on adding iodide of potassium to a solution of a protosalt of palladium. It is insoluble in water, alcohol, or ether, but is decomposed on heating with caustic potash.

Bromide of palladium much resembles the iodide.

Palladium and *chlorine* form two chlorides:—

1. Protochloride of palladium	$PdCl$
2. Bichloride of palladium	$PdCl_2$

1. *Protochloride of palladium.* The metal dissolves slowly in hydrochloric acid with production of protochloride, or quickly in aqua regia with production of bichloride. On evaporating the solution of bichloride to dryness and gently heating, the protochloride remains. It is soluble in water, and may be obtained in brown hydrated crystals. With ammonia it forms a number of interesting bodies resembling those produced by acting upon protochloride of platinum with the same agent; one of them is the *chloride of palladamine* (NH_3Pd, Cl) or chloride of ammonium, in which an equivalent of hydrogen is replaced by one of palladium. The oxide of palladamine (NH_3Pd, O) is a powerful base.

2. *Bichloride of palladium* is formed when the metal is dissolved in aqua regia. On adding chloride of potassium a red crystalline precipitate of *chloropalladiate of potassium*, or double chloride of palladium and potassium is thrown down.

Cyanide of palladium ($PdCy$). Cyanogen has a greater affinity for palladium than for any other metal. White, or slightly yellow coloured flocks of cyanide of palladium are precipitated whenever a soluble cyanide is added to a palladium salt. Cyanide of palladium is soluble in solution of cyanide of potassium, forming a double salt, which crystallises in prisms containing (KCy, PdCy, 3 Aq).

Nitrate of palladium is formed by dissolving the metal in nitric acid. It is not very stable, but by careful manipulation may be obtained in rhomboidal prisms.

Sulphate of palladium (PdO, SO_3) may be produced by boiling the nitrate with sulphuric acid. It is very deliquescent.

Alloys of palladium. Steel alloyed with one per cent. of palladium is well adapted for making cutting instruments that require a perfectly smooth edge. Four parts copper and one palladium form a white ductile alloy. One part of palladium gives with six of gold an alloy that is nearly colourless.

Tests for palladium. The colour of the iodide, and the production of the cyanide under the circumstances indicated, are the chief tests for palladium. Protochloride of tin throws down a black precipitate soluble in hydrochloric acid with production of an intensely green solution.

PALLIUM. [PALL.]

PALM. [WEIGHTS AND MEASURES.]

PALM-OIL. [OILS, MANUFACTURE OF.]

PALM-SUNDAY, the Sunday before Easter, so named because on that day boughs of palm trees used to be carried in procession, in imitation of those which the Jews strewed in our Saviour's way when he went up to Jerusalem. It is still customary with our boys, in most parts of England, to go out and gather slips with the willow flowers or blossoms at this time; these are selected as representatives of the palm, because they are generally the only plants, at this season, easily to be come at, in which the power of vegetation can be discovered. Barnaby Googe, in his 'Popish Kingdome,' 4to, Lond., 1570 (a translation from Naogeorgus), alludes to the use of willow branches, at that time, instead of palm.

Stow, in his 'Survey of London,' tells us that "in the week before Easter had ye great showes made for the fetching in of *a twisted tree, or with*, as they termed it, out of the woods into the king's house, and the like into every man's house of honour or worship." This must also have been a substitute for the palm. An instance of the remote antiquity of this practice in England is afforded by the 'Domesday Survey,' under Shropshire, vol. i., p. 252, "Terra dimid. car. Unus reddit inde *fascem buxi in Die Palmarum*."

These boughs or branches of palm, whatever they might be, underwent a regular blessing. (See the 'Missale ad Usum Ecclesiæ Sarisburiensis,' 4to, London, 1555.) In Roman Catholic churches branches of yew are carried and blessed on Palm-Sunday.

The Russians of the Greek Church have a very solemn procession on Palm-Sunday.

PALMIC ACID. [RICINELAIDIC ACID.]

PALMIN. [RICINELAIDIN.]

PALMITATE OF MYRICYL. [BEES-WAX; PALMITIC ACID.]

PALMITIC ACID ($C_{32}H_{31}O_3,HO$). *Ethalic Acid. Cetylic Acid. Oleic Acid.*—An organic acid belonging to the family represented by acetic acid. It is found in the free state in palm oil; in combination in bees wax, spermaceti, and human fat, and may be artificially obtained by the action of hot alkalies upon ethal or oleic acid.

To prepare the acid from palm oil, the latter must be saponified by caustic soda or potash, and the soap decomposed by hydrochloric acid. The mixture of oleic and palmitic acids thus set at liberty must now be dissolved in alcohol and the alcoholic solution set aside to crystallise. The palmitic acid crystallises out whilst the oleic acid remains in solution; the latter acid is however only removed after several recrystallisations.

Palmitic acid is a colourless, crystalline, inodorous and tasteless solid. It is insoluble in water, upon which it floats, but very soluble in boiling alcohol and ether. It fuses at 144° Fahr., and volatilises without residue at a high temperature. By long exposure to air at an elevated temperature it is said to lose carbon and hydrogen, and to be transformed into *palmitonic acid* ($C_{31}H_{31}O_4$) but this is doubtful.

Palmitic acid unites with bases forming salts, which have the general formula:

$$\left.\begin{matrix} C_{32}H_{31}O_2 \\ M \end{matrix}\right\} O_2$$

With the exception of the salts of the alkalies, all the palmitates are insoluble in water.

Palmitic acid also unites with glycerin, forming the following compounds:

Monopalmitin	$C_{38}H_{38}O_8$
Dipalmitin	$C_{70}H_{70}O_{13}$
Tetrapalmitin	$C_{134}H_{130}O_{16}$

Tetrapalmitin is said to be identical with the natural compound of palmitic acid with glycerin—*palmitin*, the formula of which is generally written $C_{70}H_{66}O_8$.

The following are some of the most important of the remaining compounds of palmitic acid.

Palmitic ether	$C_{32}H_{31}(C_4H_5)O_4$
Palmitate of cetyl, or cetin	$C_{32}H_{31}(C_{32}H_{33})O_4$
Palmitate of myricyl, or myricin	$C_{32}H_{31}(C_{60}H_{61})O_4$

PALMITIC ETHER. [PALMITIC ACID.]

PALMITIC GROUP. A small family of organic compounds containing the radical *palmityl* or its derivatives. The following are the most important of these compounds. [PALMITIC SERIES.]

Hydride of palmityl or cetylic aldehyde	$C_{32}H_{31}O_2, H$
Palmitone or ethalone	$C_{30}H_{31}, C_{32}H_{31}O_2$
Palmitic acid	$\left.\begin{matrix} C_{32}H_{31}O_2 \\ H \end{matrix}\right\} O_2$

PALMITIC SERIES. A division of organic bodies in Gerhard's system of classification, homologous with the acetic series of bodies. It is divided into two groups, namely

Palmitic group. Oleic group.

The palmitic group is homologous with the formic and acetic groups, whilst the oleic group has its homologues in the acrylic and angelic groups.

PALMITIN. [PALMITIC ACID.]

PALMITONE. [PALMITIC GROUP.]

PALMITONIC ACID. [PALMITIC ACID.]

PALMITYL. [PALMITIC GROUP.]

PALSY. [PARALYSIS.]

PAN, a deity of the Greek mythology, whose country was Arcadia. He is said by Homer to be the son of Hermes by the daughter of Dryops; but other writers, while calling Hermes his father, give him a different mother; while some make him to have been of different descent on the side of father as well as mother. He was the tutelar god of the shepherds. Pan is sometimes represented with sprouting horns, a goat's beard, a goat's tail, and goat's feet, holding the syrinx, a kind of musical pipe, which he was said to have invented. But in older Greek art he is often without these animal appendages; as in the terminal statue in the British Museum. The satyrs are his attendants; and hence they are sometimes called Panes. In Greek art he is figured with nymphs and satyrs as well as alone. Pan is mentioned in the early mythi as having been present at the battle of the Titans, whom he assisted in routing by frightening them by a wild noise which he produced by blowing in a sea-shell. He was also said to have accompanied Bacchus to India, and that upon one occasion, by uttering a loud scream, which was repeated by the echoes, he scared away the enemy. From these incidents the expression "panic fear," meaning a terror produced by no obvious or sufficient cause, appears to have been derived. He is sometimes represented as the god of terror. Pan was worshipped at Athens and most other Greek cities. His worship was introduced into Italy at an early period, where he was identified with an earlier god, Inuus; and festivals, called Lupercalia, were instituted

in honour of Pan Lupercus, the protector of the flocks against wolves. According to Servius (note to Virgil's 'Eclogues,' ii. 31) Pan was also considered as the god of Nature, a personification of the universe, the word *pan* (πᾶν), in Greek, meaning "all," or "the whole," but this was a late notion.

PANATHENÆA (Παναθήναια), the greatest of the Athenian festivals, was celebrated in honour of Athena (Minerva) as the guardian deity of the city ('Αθήνη πολιάς). It is said to have been instituted by Erichthonius, son of Hephæstus (Harpocrat., Παναθ.), and to have been called originally Athenæa ('Αθηναια); but it obtained the name of Panathenæa in the time of Theseus, in consequence of his uniting into one state the different independent states into which Attica had been previously divided. (Paus., viii., 2, s. 1; Plut., 'Thes.,' c. 20; Thucyd., ii. 15.)

There were two Athenian festivals, which had the name of Panathenæa: one of which was called the Great Panathenæa (μεγάλα Παναθήναια), which was celebrated once in every five years with very great magnificence, and attracted spectators from all parts of Greece; and the other, the Less Panathenæa (μικρά Παναθήναια), which was celebrated every year in the Piræus. (Harpocrat., loc. cit.; Plato, 'De Rep.,' i. 1.) When the Greek writers speak simply of the festival of the Panathenæa, it is sometimes difficult to determine which of the two is alluded to; but when the Panathanæa is spoken of by itself, and there is nothing in the context to mark the contrary, the presumption is that the Great Panathenæa is meant; and it is thus spoken of by Herodotus (v. 56) and Demosthenes ('De Fals. Leg.,' p. 394).

The Great Panathenæa was celebrated on the 28th day of Hecatombæon (Proclus, quoted by Clinton, 'Fast. Hell.,' p. 325), the first of the Athenian months, which agrees with the account of Demosthenes ('C. Timocr.,' p. 708, 709), who places it after the 12th day of the month. There is considerable dispute as to the time in which the Less Panathenæa was celebrated. Meursius places its celebration in Thargelion, the eleventh of the Athenian months; but Petitus and Corsini, in Hecatombæon. Mr. Clinton, who has examined the subject at considerable length ('Fast. Hell.,' p. 332–335), supports the opinion of Meursius; and it does not appear improbable that the Less Panathenæa was celebrated in the same month as the Great, and was perhaps omitted in the year in which the great festival occurred. The celebration of the Great Panathenæa only lasted one day in the time of Hipparchus (Thucyd., vi. 56); but it was continued in later times for several days.

At both of the Panathenæa there were gymnastic games (Pind., 'Isthm.,' iv. 42; Pollux, viii. 93), among which the torch-race seems to have been very popular. There were also chariot and horse races. In the time of Socrates, there was introduced at the Less Panathenæa a torch-race on horseback. (Plato, 'De Rep.,' i. 1.) At the Great Panathenæa there was also a musical contest, and a recitation of the Homeric poems by rhapsodists. (Lycurg., 'C. Leocr.,' p. 209.) The victors in these contests were rewarded with vessels of sacred oil. ('Pind., 'Nem.,' x. 64, and Scholia; Schol. on 'Soph. Oed. Col.,' 698.)

The most celebrated part however of the Great Panathenaic festival was the solemn procession (πομπή), in which the Peplus (Πέπλος) or sacred robe of Athena was carried through the Ceramicus and other principal parts of the city to the Parthenon, and suspended before the statue of the goddess within. This Peplus was covered with embroidery (ποικίλματα, Plato, 'Euthyph.,' c. 6), on which was represented the Battle of the Gods and the Giants, especially the exploits of Zeus and Athena (Plato, loc. cit.; Eurip., 'Hecub.,' 468), and also the achievements of the heroes in the Attic mythology, whence Aristophanes speaks of "men worthy of this land and of the Peplus." ('Equit.,' 564.) The embroidery was worked by young virgins of the noblest families in Athens (called ἐργαστῖναι), of whom two were superintendents, with the name of Arrephoræ. When the festival was celebrated, the Peplus was brought down from the Acropolis, where it had been worked, and was suspended like a sail upon a ship (Paus., xxix. 1, s. 1), which was then drawn through the principal parts of the city. The procession which accompanied it consisted of persons of all ages and both sexes, of foreigners resident at Athens as well as of citizens. The old men carried olive branches in their hands, whence they were called Thallophori (Θαλλοφόροι), and the young men appeared with arms in their hands, at least in the time of Hipparchus. (Thucyd., vi 56.) The young women carried baskets on their heads, whence they were called Canephori (κανηφόροι). The sacrifices were very numerous on this occasion. During the supremacy of Athens every subject state had to furnish an ox for the festival. (Schol. on Aristoph. 'Nub.,' 385.) It was a season of general joy; even prisoners were accustomed to be liberated, that they might take part in the general rejoicing. (Schol. on Demosth. 'Timocr.,' 184.) After the battle of Marathon, it was usual for the herald at the Great Panathenæa to pray for the good of the Platæans as well as of the Athenians. (Herod., vi. 111.)

The procession, which has been described above, formed the subject of the bas-reliefs which embellished the outside of the temple of the Parthenon, which are generally known by the name of the Panathenaic frieze. The blocks of marble of which this frieze was originally composed, were 3 feet 4 inches high, and they formed a connected series of 524 feet in length. A considerable portion of this frieze, which is one of the most splendid of the ancient works of art, is in the British Museum. [Elgin Marbles.]

A full and detailed account of this festival is given by Meursius, in a work on the subject, which is printed in the seventh volume of the 'Thesaurus' of Gronovius.

PANCAKE, a thin cake of batter fried or baked in a pan. The annual custom of frying pancakes (in turning or tossing which in the pan there was usually a good deal of pleasantry in the kitchen) is still retained in many families throughout the kingdom on Shrove Tuesday, and was formerly universal. The church bell which used to be rung on that day, to call the people together, in Roman Catholic times, for the purpose of confessing their sins, or shriving themselves, was called the pancake-bell, a name which it long retained.

According to Brand ('Popular Antiq.'), a kind of pancake feast preceding Lent was used in the Greek Church, from whence we probably have borrowed it, and pancakes are eaten at any time, though more generally on Shrove Tuesday. The Russes, Hakluyt says, begin their Lent always eight weeks before Easter. The first week they eat eggs, milk, cheese, and butter, and make great cheer with pancakes and such other things.

PANCHA-TANTRA. [Pilpay, in Biog. Div.]

PANDECT. [Justinian's Legislation.]

PANDUS. [Mahabharata.]

PANEGYRIC (from the Greek 'panegyricus,' πανηγυρικος λόγος) is a species of oration in praise of a person or thing, so called because such discourses used to be delivered in ancient Greece on the occasion of great public festivals before the whole assembly, "panégyris," of the people. Afterwards the name came to be applied to political orations delivered in the senate or council of a state in praise of that state or of the leading men or man in it. The panegyrical oration of Isocrates is a fine specimen of the kind, in which he commemorates the glories of Athens, the services which it had rendered to Greece in general, and the whole with a view to nourish friendly feelings between it and the other Greek states.

Under the Roman empire panegyrics were composed in praise of the emperors, Pliny's panegyric of Trajan is a well known specimen of this kind. Panegyrics became frequent under the late emperors, both of the East and the West, in Greek and in Latin; they are mostly however written in a fulsome and adulatory style. We have panegyrics of Constantine, Constantius, Justinian, Theodosius, and others, which, if consulted with discrimination, may be useful for historical purposes and for supplying deficiencies in the historians of those times. Eunodius, bishop of Pavia, wrote a panegyric in praise of Theodoric.

Panegyrics have also been written in verse. The poem of Tibullus in praise of Messala is a specimen of this kind, as well as similar compositions by Claudianus, Sidonius, and others.

In modern times panegyrics have been written by Roman Catholic preachers in honour of particular saints. Giordani, an Italian contemporary author, wrote a panegyric in praise of Napoleon, in imitation of that of Pliny. But the panegyrical style seems no longer in accordance with the taste of our age, and its essential character is too laudatory to please minds of an independent cast. The *éloges* on deceased members of the Académie Française are perhaps the only existing examples of the old panegyric.

PANEL. This term in English law denotes a small schedule of paper or parchment containing the names of the jurors returned by the sheriff for the trial of issues in courts of common law. The enrolment of the names upon this schedule is the *array*. The etymology of the term is doubtful; Sir Edward Coke says, "Panel is an English word, and signifieth a little part, for a *pane* is a part, and a panel is a little part' (Co. Litt., 158 b). Spelman derives the word from *pagella*, a little page, supposing the *g* to be changed to *n*. (Spelman's 'Gloss.,' tit. "Panella"). Both these etymologies seem to be incorrect. In the old book called 'Les Termes de la Ley,' *panel* is said to come from the French word *panne*, a skin; whence in barbarous Latin might come *panellus* or *panella*, signifying a little skin of parchment. This would denote the jury panel pretty accurately, and the history of its appearance as an expression in English procedure is consistent with its derivation from the French.

In the earliest records of the forms of jury-process, as given by Glanville, it appears that the sheriff was commanded by the writs in certain real actions to cause to be imbreviated (imbreviari facere) the names of the jurors by whom the land in question was viewed. But at this time the word *panel* never occurs, nor is it used by Bracton, Fleta, or Britton, nor in any statute earlier than 20 Edw. III., c. 6 (1349), which forbids sheriffs from putting suspected persons in *arrays of panels*. This was precisely the period at which the French language began to be fully introduced into our law proceedings. (Luder's 'Tract on the Use of the French Languge in our Ancient Laws.')

In Scotch criminal law, the accused, who is called a defender till his appearance to answer a charge, is afterwards styled the *pannel*. The etymology of this word also is doubtful. (Jameson's 'Dictionary,' ad verb.) But it is possible that it may have the same origin as our English word, as in Scotch proceedings a prisoner is sometimes said to be *entered in pannel* to stand trial. (Arnot's 'Criminal Trials,' p. 12.)

PANOPTICON. [Bentham, in Biog. Div.]

PANORA'MA (from the Greek word πᾶν, all, and ὅραμα, a view), a picture showing a view completely around the spectator. This in-gigantic pictorial contrivance was first devised by an English artist, Robert Barker, about the year 1794; and is not so much a new mode of painting—the process itself being similar to scene-painting or to distemper—as a novel application of it. Contrary to the diorama [DIORAMA], the panorama forms the surface of a hollow cylinder, or rotunda (whence it is frequently called in German *Rundgemälde* or *Rundbild*—cyclorama), in the centre of which is a detached circular platform for the spectators, covered overhead to conceal the skylight, and thereby increase the illusion and give greater effect to the painting itself. The latter is not painted on the walls, but upon canvas, like the scenes of a theatre, and afterwards fixed up, in order that the views may be changed, and a fresh one may be in progress while another is open for exhibition. Yet although there is nothing whatever particular in regard to the execution or process of such pictures, they are attended with difficulties which can be mastered only by practice and experience. The first of these arises from the circumstance that the artist cannot either concentrate his light or adapt the direction of it arbitrarily as best suits his purpose, but while portions of his view will be entirely in sunshine, the opposite one will be almost a mass of shadow; the second is the difficulty of representing on a curved surface the straight horizontal lines of buildings; the third and greatest of all is, that there can be no single fixed point of sight, since the eye traverses around the whole circle of the horizon. Hence it might be supposed that many parts of such a picture would appear, if not quite distorted, more or less out of perspective. Yet such is not the case, no doubt partly because the eye accommodates itself to certain principal points fixed upon by the artist as centres of vision, and on account of the optical fascination attending the whole. The subjects generally chosen are views of cities, or interesting sites, whose entire locality and buildings may thus be vividly placed before the eye in a manner no less instructive than it is interesting.

Among the largest panoramas hitherto attempted was the view of London by day, and of Paris by night, at the Colosseum in the Regent's Park. An improvement on this sort of panorama, is what is styled the moving panorama. This, which is also painted on canvas, by being wound on and off a cylinder, has been used to depict a continuous extent of scenery of many thousands of miles. Such were the panoramas of the Mississippi and Ohio rivers, and many others.

PANSY, a corruption of the French *pensée*, is a name now chiefly applied to the garden varieties of Viola tricolor, Attaica, and others, which are commonly cultivated under the name of Heart's-ease. These plants, being all nearly allied to each other, have proved an abundant source of hybrids, which by repeated crossing and selecting, have at length been so much improved in their appearance that it is not uncommon to meet with single flowers as large as a penny piece, although the wild blossom of Viola tricolor will hardly cover a sixpence. When skilfully managed, they are great ornaments of the flower beds in a garden, but they are short-lived, and require to be continually renewed by seeds or cuttings. They love damp rich soil, not too much exposed to the sun, and are thought to acquire the greatest health and beauty when planted in beds of light rich earth upon a thick substratum of cow dung, into which their roots will quickly penetrate.

PANTHEON. [ROME, in GEOG. DIV.]

PANTOGRAPH, sometimes improperly called PENTAGRAPH, is an instrument employed in copying maps, plans, and other drawings.

The annexed diagram represents that most commonly in use.

It is composed of four brass rules or bars, jointed to each other at the points E D B F. These joints require to be carefully executed, as upon the smoothness and steadiness of their motion the accuracy of the instrument principally depends. In those of the best construction there is a small metal cock screwed to the bar of each joint, which supports the upper end of the axis upon which it turns. This is a material improvement upon the common flat compass joint, as, besides lengthening the axis, it gives additional strength to the bar where it most requires it. A joint of this construction is shown in *fig.* 2.

At the point C is fixed a small tube which carries the tracing point, so fitted as to move freely within it, but without shaking; *fig.* 3 represents the tracer within the tube. The bar E D and the lower part of the bar A B are furnished each with a tube, *fig.* 4, similar to that at C, but moveable on the bar, with a similar screw to fasten it down at any required point. *Fig.* 5 is the pencil stem, which fits either of the tubes in the same manner as the tracer; on the top of the stem is a cup to receive a small weight to keep it down upon the paper, and the lower end carries a pencil, or, which is better, a "Mordan's point." A silk cord is attached to the pencil stem, carried through eyes made for the purpose, over the joints E B F, one of which is shown on the top of *fig.* 2, and fixed in a notch in the top of the tracer, *fig.* 3, so that the pressure of the thumb upon the cord lifts the pencil from the paper when required. *Fig.* 6 is a flat leaden weight with a brass stem rising out of it, which fits in the tubes in the same manner as the pencil and tracing point; this is called the fulcrum, as being the point upon which the whole instrument moves; the weight has three or four fine points on its under surface to keep it from shifting upon the paper. The whole instrument is supported by six revolving feet or castors, which should move very freely in all directions. One of these castors is shown under the joint, *fig.* 2. The pin or fulcrum is placed near the edge of the weight, so as to allow room for the castor to work when the fulcrum is near the points A or D.

Fig. 1.

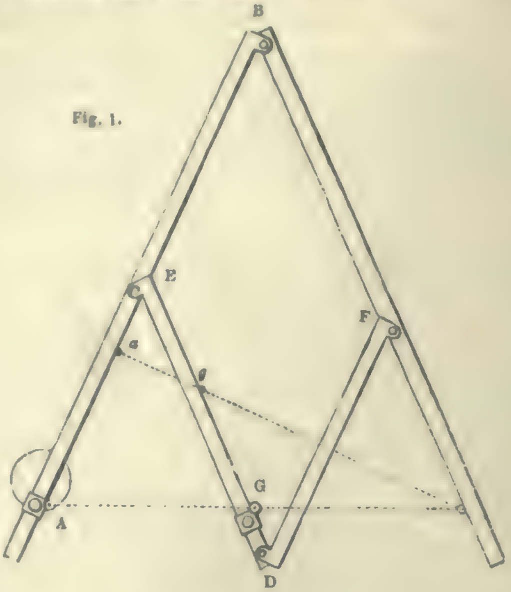

Fig 2.

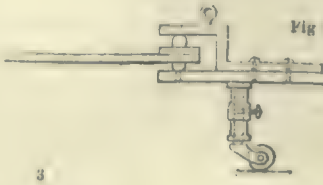
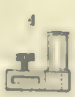


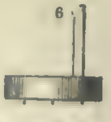
3

4



5

6



The proportion of the bars is of no consequence, so that E D is equal to B F and E B to F D, in which case they will always form a parallelogram, by which name the instrument is sometimes called. Now if the tracer at C is carried over the lines of the plan, the fulcrum-tube being fixed at A, and the pencil-tube at G, the pencil will make an exact copy of every line, but only half the size of the original, which may be proved in the following manner:—

The points A, G, and C, are capable of being brought close together, and when the instrument is open, as in the figure, G is exactly half way between C and A; C then travels twice as quickly as G in the direction A G C, so that to whatever extent the pantograph may be opened, G and C being considered as points in a lever of which A is the fulcrum, it will be seen that if C is made to describe an arc of a circle of any radius, G at the same time is describing an arc of a circle of half the radius, so that C moves in a direction perpendicular to A G C twice as fast as G. Now it was shown above that it moved twice as fast as G in the direction A G C, and as by the composition of these two motions, all lines, whether rectilinear or curved, are produced, it follows that the pencil at G will produce a copy half the size of the original traced over by the point at C, as before stated.

To produce a copy one-fourth the size of the original, we must shift the pencil from G to *g*, and the fulcrum from A to *a*, *a g* being one-fourth the length of *a* C, and so on for all other proportions *less* than half, the constant rule being—"As the distance of the pencil from the fulcrum is to the distance of the tracer from the fulcrum, so will be the size of the copy to that of the original." No calculation is required in practice, as the arms A E and E D are graduated for all proportions from one twelfth to eleven twelfths inclusive. If it be required to produce a copy *more* than half the size of the original, the fulcrum must be placed on the arm F D, and the pencil on A E, the rule above given still holding good, so that for a copy the *same size* as the original the fulcrum must be placed at G, and the pencil at A. It must be borne in mind, however, that when the fulcrum is on the arm E D, the copy will be inverted.

Though the principle of this instrument is as simple and complete as can be imagined, yet it falls sadly short of perfection in practice.

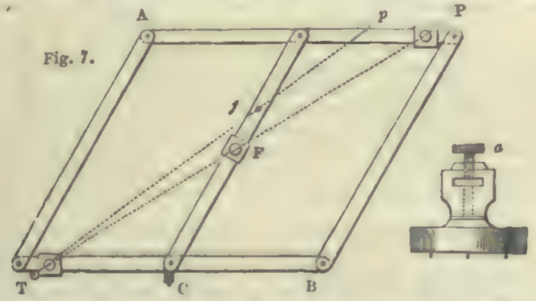
In the first place the numerous joints and castors, however carefully constructed, make it heavy to the hand in comparison with the unfettered pencil, and it requires much practice to be able to manage it so dexterously as to get those minute and gentle undulations, necessary not only to the beauty but to the utility of the drawing. The pencil too, constantly working upright, does not maintain that fine point which is required for distinctness of outline, and to these faults we must add inaccuracy of workmanship, however slight, the effect of wear, inequalities of the paper, and other accidents.

The best way to test an instrument is to reverse the position of the tracer and pencil, thus producing a copy larger than the original, when the defects will of course be exaggerated in proportion.

The pantograph, however, though it cannot be depended upon for an accurate and finished copy, is of great service to the draughtsman, for by it may be marked off all the principal points through which to draw the lines of a plan with equal accuracy and infinitely greater facility than by any other means used for the purpose.

The annexed engraving represents a pantograph which possesses some advantages over that before described. In the first place, the fulcrum being in the centre, it requires but one castor, which is placed at C, and makes it work much lighter in hand than the old instrument, which has six; besides which these six castors are frequently a source of annoyance by getting off the edge of the drawing-board and running over drawing-pins or anything else which may happen to be in the way. Secondly, the shape of this instrument allows it to move as freely when nearly closed as when opened wide, which is not the case with the other. This improved instrument consists of six bars, moving freely about each other at the six points of juncture, so arranged with regard to length that A P and T B are always parallel to each other. F is the fulcrum, furnished with a socket and screw (*a*), through which the centre bar can be moved, and which can be fastened down at any of the graduations on that bar. This socket, with the bar, turns upon the pin rising out of the centre of the flat weight, as shown in the diagram. Now the tracer T, the fulcrum F, and the pencil P must always be in a straight line. To produce a copy the same size as the original, the fulcrum must be in the centre, and the pencil and tracer, as in the engraving, equi-distant from the centres of their respective arms, and consequently from the fulcrum. For a half-sized copy the pencil must be shifted half way up the arm to *p*, and the fulcrum to *f*, in the straight line T *f p*, and so on for any required proportion, which is apparent by a glance at the diagram. The rule laid down in regard to the other instrument holds good for this, the copy bearing the same proportion to the original as the distance of the pencil from the fulcrum does to that of the tracer.

Fig. 7.



In using the pantograph it is frequently necessary to copy the drawing in divisions, on account of the instrument not being large enough to extend over the whole surface at once. In this case the greatest care is requisite to join the lines of one division accurately to those of the adjoining division. The best way of effecting this is to hold the tracer down upon a point in the original by one hand, moving the fulcrum about with the other, until the pencil exactly coincides with the corresponding point in the copy. To ensure accuracy, this should be tried with three or more points, as the least deviation will throw the whole plan out of position.

In practice a large number of plans are copied of the same size as the original. The quickest method, which, however, requires great care, is to pin down a piece of tracing-paper upon the original, on which the lines are marked with a fine-pointed pencil. A piece of paper rubbed over with blacklead is then placed upon the paper intended for the copy, with the black side downwards, and the tracing-paper is pinned down upon it; the lines then are carefully traced over with a steel point, and the pressure transfers the blacklead to the drawing paper beneath. The black paper is sometimes omitted, and the lines, traced by slight indentations only, are finished by hand, in the usual manner.

If it is required to reduce a plan, and the draughtsman does not possess a pantograph, the usual way is to divide the original and the paper for the copy, whatever the relative size, into the same number of squares, which will of course then bear the same proportion to each other as the surfaces of which they are divisions. The lines must then be set in singly, either by the assistance of the proportional compass or scale, or by a geometrical scale drawn for the occasion. The following method is dependent only upon the compass and T square.

Draw a triangle in which A B is the base, and make A C bear the same proportion to C B as you wish the copy to bear to the original; take any distance on the original, and set it off from B on B C, draw a line parallel to A B, and that portion of A C cut off by such parallel wi bear the required proportion to the distance set off on B C, as may be seen by the divisions 1 2 3 4 on the two sides of the triangle in the diagram. The triangle should be drawn in ink, and the distances, being marked in pencil, may be rubbed out when transferred to the paper. [EIDOGRAPH; PROPORTIONAL COMPASSES.]

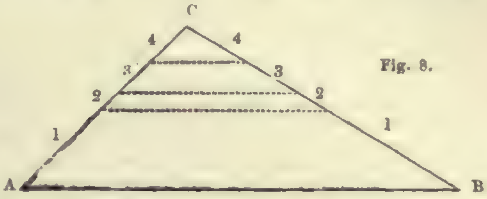


Fig. 8.

PANTOMIME, the name of a species of dramatic performance in which the actors express themselves by gestures. The name is composed of two Greek words, meaning "imitation of every thing." Pantomimic acting, accompanied by music, has been in use among the Chinese, Persians, and other Oriental people from the oldest times. The Greeks introduced the pantomime in their choruses, some of the actors dancing and gesticulating, accompanied by music, whilst others sang. (Lucian, 'De Saltatione.') The Romans had entire dramatic representations consisting of dance and gestures only, styled "saltatio pantomimorum," and some of their performers attained a high degree of excellence in the art. Two of them, Bathyllus and Pylades, in the time of Augustus, have been celebrated by the Roman writers.

In modern times pantomimic balls, representing an entire dramatic action or fable, have become a favourite scenic performance. The Tuscan Angiolini, in the last century, and after him Viganò, who died at Milan in 1821, have excelled in this species of composition. Noverre, in France, distinguished himself likewise in the composition of pantomimic "ballets." The name is now commonly applied to the harlequinade theatrical performances exhibited in London at Christmas and Easter.

(Meursius, *Orchestra*; Signorelli, *Storia Critica dei Teatri antichi e moderni*.)

PAPA'VER. OPIUM, *Medical Properties of.* The juice of the unripe capsule or fruit of the *Papaver somniferum* seems to have been used on account of its narcotic powers from a very early period, first in the East, of which it is a native, and afterwards in the West.

As to the two varieties of the *P. somniferum*, called *P. S. album*, in which the seeds are white, and the openings under the stigmata obliterated, and *P. S. nigrum*, in which the seeds are blackish-gray, and the openings under the stigmata perfect, some differences are found in the relative proportion of some of the chemical constituents of the opium procured from them; but the *P. S. album* (*Papaver officinale*, Gmelin) is the kind chiefly cultivated in Persia and India.

"The first sophistication which the juice receives is that practised by the peasants who collect it, and who lightly scrape the epidermis from the shell to augment the weight. This operation adds about one-twelfth of foreign matters. Thus collected, opium has the form of a glutinous and granular jelly. It is deposited in small earthen vessels, and beat up with saliva. On inquiring why water was not employed in the place of saliva, the answer was, that water caused it to spoil. It is afterwards enveloped in dry leaves, and in this state is sold. The seeds of those poppies which have yielded opium are equally good for sowing the following year." Such is the account by M. Ch. Texier, of the plan in Asia Minor. A change of seed, however, by obtaining some from a distant locality, seems expedient. (Dr. Eatwell, in 'Pharm. Journal,' vols. xi. and xii., 1852.) In India, the juice is mixed with oil obtained from the seed of the poppy, to hinder the rapid drying of the juice. The produce of the first excisions is of a light yellow colour; the others are fainter in odour and darker coloured. In general, all three gatherings are mixed together, and sent to market in small baskets. The quantity obtained varies not only with the soil and mode of cultivation, but also with the season and the time of collecting. In wet gloomy seasons, not only is the quantity less, but it does not keep well; in such a case the proportion of *morphia* is also less. The quantity of morphia depends likewise very much on the time of gathering: if the harvest be postponed till the capsules begin to turn white and hard, it is generally deficient, and by the time the capsules are mature and the seeds ripe it has entirely disappeared. It is not, as is the case of many other vegetable alkaloids, transferred to the seeds, as they are altogether devoid of any narcotic principle, the oil which is obtained from them being bland and wholesome, and abundantly used as food; even the seeds themselves are freely eaten by birds, to which they are given (from the black variety) under the name of maw-seeds. In India and Turkey they are made into comfits, or strewed over sweetmeats, like carraway seeds.

Several varieties of opium are met with in commerce, which may be noticed here in the order of their reputed excellence, the quantity of morphia contained in each being assumed as the criterion.

1, *Smyrna* or *Levant opium*, which Dr. Pereira considers synonymous with Turkey opium, though German pharmacologists deem Turkey and Egyptian opium to be synonymous. (Th. Martius, 'Pharmakognosie.') "It occurs in irregular roundish or flattened masses of various sizes, rarely exceeding two pounds in weight, enveloped in leaves, and surrounded with the reddish triangular capsules of several species of *Rumex*, such as *R. orientalis*, *R. patientia* (which are employed to prevent the masses cohering to each other while the opium is soft). When first imported, the masses are soft, and of a reddish-brown colour, but by keeping they become hard and blackish, and on this account it is termed by the French *opium noir*. Its consistence is soft, at least of the interior, even when the exterior is very hard. Its lustre is waxy; the taste, bitter, acrid, and persistent.

2. "*Constantinople opium.* Of this there are two sorts: one in large irregular cakes, which are flattened, like the Smyrna opium, and of very good quality; the other is in small flattened regular cakes, of a lenticular form, from 2 to 2½ inches in diameter, and covered with a poppy leaf, the midrib of which divides the disk into two parts. It has an odour similar to the preceding kind, but more feeble; at first it is reddish both without and within, hence called by the French *opium rouge*; it however blackens and dries in the air, but never becomes so hard as Smyrna or Egyptian opium, than which it is more mucilaginous." Th. Martius is of opinion that it is a manufactured article, prepared at Constantinople, out of Smyrna opium, by the addition of gum. It is a common article of German, but rarely of English, commerce. It is never covered with the *Rumex* capsules as the Smyrna opium.

3. *Egyptian* or *Alexandrian opium* "occurs in round flattened cakes of about three inches in diameter, covered externally with the vestiges of the same leaf, which are in too mutilated a state to be determined. It is distinguished from the preceding varieties by its reddish colour, analogous to soccotrine or hepatic aloes, which does not by time or exposure to the air become darker; the odour is fainter and somewhat musty." Though the cakes are all of the sorts much the hardest, so that a blow with a hammer will cause one to split into fragments, yet by exposure to the air it becomes soft.

4. "*Trebizond* or *Persian opium* occurs in the form of cylindrical sticks, which by pressure have become somewhat angular. Their length is about six inches; their diameter about six inches. Each one is enveloped in a smooth shiney paper, and tied with cotton. The colour of opium is similar to that of soccotrine aloes. It possesses a stronger odour than the Egyptian kind, but fainter than that of Smyrna, united with a musty one. The taste is intensely bitter."

5. *Indian opium*, of which there are several varieties, as already described. [OPIUM TRADE.]

6. *English opium* "is in flat cakes or balls enveloped in leaves. It resembles the Egyptian more than any other kind; its colour is that of hepatic aloes, with a moderately strong opiate odour."

Before offering a summary of the points of difference, in chemical composition and other respects, of these various sorts, it is necessary to enumerate the general constituents of opium:—1, morphia; 2, codeia; 3, paramorphia or thebaine; 4, pseudomorphia; 5, narcotina or opianum; 6, narceine; 7, meconine; 8, meconic acid; 9, an oily acid; 10, gum; 11, resin; 12, extractive; 13, a fixed oil; 14, caoutchouc; 15, a volatile odorous principle; 16, ligneous matter with inorganic salts, such as sulphate of lime and potass, and in some kinds opiania, papaverine, and porphyroxine, the latter principle only in Bengal and Smyrna opium (according to Merck, its discoverer, 'Pharm. Central Blatt,' June, 1837). There are also various accidental but more intentional impurities, such as sand, of which even the best Smyrna opium contains a large portion, 10 ounces of opium frequently containing 10 drachms of stones and gravel. In the interior of the cakes leaden bullets are often discovered. The cakes should always be cut through the centre in order to detect this fraud.

The relative proportion of these numerous ingredients varies very much, not only in the samples from different countries, but in those of the same country. Thus, Smyrna opium, though the average quantity of morphia which it yields may be stated to be 10 per cent., in five specimens examined by Mulder gave 10 per cent. in the best and little more than 2 in the worst.

Professor Guibourt states Constantinople opium to yield only one-half the quantity of morphia procurable from Smyrna opium; while Mr. Duncan of Edinburgh has obtained even 14 per cent. Guibourt also affirms that Egyptian opium yields only 5-7ths of the morphia obtainable from Smyrna opium; while Dr. Christison procured 10½ per cent. from it. Of the Indian kinds, Dr. Smyttan procured only 3 or 5 per cent. of morphia, while Dr. Christison obtained 9½ from the Malwa opium; and from Bengal opium Dr. Smyttan obtained 2 or 3½ per cent., while Mr. Macfarlane of Edinburgh procured 7 per cent.

From English opium 5 per cent. may be obtained. From German opium Blitz procured 16½ to 20 per cent. From some French opium Petit obtained 16 to 18 per cent, and Caventou the large amount of 22 to 28 per cent.

The extreme discrepancy of these results may be explained not merely by the varying seasons when the specimens were produced, and the different degrees of skill and dexterity in the chemists, but by the fact that the morphia is more easily and effectually separated when the opium is fresh: hence the large proportion found in European opium, which was not only cultivated with great care, but was analysed soon after it had been collected. It is not at all improbable that the morphia undergoes a change by age, and entirely evaporates from old specimens, in the same way as conia disappears from hemlock. [CONIUM, in NAT. HIST. DIV.]

It is always proper to institute an examination into each new purchase of opium, to ascertain the presence and amount of morphia. Some specimens of opium, which to the eye present all the physical characters of the best Smyrna opium, even some of those deemed hitherto inimitable, such as the transparent agglutinated tears seen on cutting it across, are found on analysis devoid of the smallest trace of morphia. ('Journal de Pharmacie,' tom. xxiv., pp. 325, 446.)

The following test is proposed in the 'New Edinburgh Pharmacopœia,' and though not absolutely certain, is sufficiently so for common use:—"A solution from 100 grains, macerated 24 hours in two fluid ounces of water, filtered and strongly squeezed in a cloth, if precipitated by a cold solution of half an ounce of carbonate of soda in two waters, and heated till the precipitate shrinks and fuses, will yield a solid mass on cooling, which weighs, when dry, at least 11 grains; and if pulverised, dissolves entirely in solution of oxalic acid."

More morphia would appear to be present in the specimens of European opium, which are obtained from the variety of poppy with violet-coloured petals, than in the Turkey opium; while that from the European white variety contains more narcotine than the Turkey. In Smyrna opium the morphia seems to be united with meconic acid, and to be not only more abundant, but more easily separated, and more completely purified from the narcotine and colouring matter, than that of Egypt, in which the morphia is united to sulphuric acid.

The following table, by Dr. Pereira, will show at one view the principal characters of the crystalline constituents of opium:—

TABULAR VIEW OF THE PRINCIPAL CHARACTERS OF THE CRYSTALLINE PRINCIPLES OF OPIUM.

Characters.	Morphia.	Codeia.	Narcotina.	Meconine.	Narceine.	Paramorphia, or Thebaine.	Pseudomorphia.
Taste . . .	Bitter	Bitter	Insipid	Rather acrid	Slightly bitter and metallic	Rather acrid and metallic	..
Fuses at . . .	Above 240°	320°, or in boiling water	338°	194°, or in boiling water	198°, or in boiling water	302°	Hardly fusible
In cold water .	Nearly insoluble	Soluble in 80 parts	Insoluble	Soluble in 265 parts	Soluble in 375 parts	Scarcely soluble	Almost insoluble
In boiling water .	Soluble in 100 parts	In 17 parts	Slightly soluble	In 18 parts	In 230 parts	..	Almost insoluble
In cold alcohol . .	Soluble in 40 parts	Soluble	In 100 parts	Soluble	Soluble	Soluble in 10 parts	Almost insoluble
In cold ether .	Sparingly soluble	Easily soluble	Easily soluble	Soluble	Insoluble	Very soluble	Almost insoluble
In caustic alkalies .	Soluble	Insoluble	Insoluble	Soluble	Insoluble	Insoluble, except in very concentrated solutions	Very soluble in potass and soda
Chlorine . .	..	..	..	Coloured blood-red	..	..	..
Iodine . . .	..	..	..	..	Coloured blue	..	..
Nitric acid . .	Coloured red	..	..	Yellow	If dilute, blue	Yellow	Coloured red
Hydrochloric acid .	..	..	..	..	Blue	..	..
Iodic acid . . .	Iodine set free	..	..	..	..	..	..
Perchloride of iron	Coloured blue	..	..	..	..	..	Coloured blue
Infusion of galls .	Precipitate	Precipitate	Precipitate	..	..	..	..

Atomic weight . .	292	284	446	97	298	202	306
Action on vegetable colours	Alkaline	Alkaline	No effect	No effect	No effect	Alkaline	..
Reaction to acids .	Salifiable	Salifiable	Salifiable	Not salifiable	Not salifiable	Not salifiable	Not salifiable
Effects . . .	Poisonous; a cerebro-spinant	A cerebro-spinant	Inert ?	Inert ?	Inert ?	Causes convulsions	Not poisonous

The great pains now taken in the culture and preparation of Indian opium induce a preference for it over the other kinds. If Indian opium contain generally more narcotine, it is on that account perhaps better suited to cases in which the stimulating action is wished.

Good opium is not perfectly soluble in water; $\frac{1}{12}$th generally remains undissolved, consisting of the caoutchouc and resin. Constantinople opium, however, leaves no residuum of caoutchouc. When opium is entirely soluble in water, it may be suspected to have been prepared by boiling the bruised capsules and leaves, and it is of a very inferior kind. The specific gravity of good opium is 1·336, if great mechanical impurities are not present. It is very inflammable, and burns with a clear flame, and forms a transparent alcoholic solution. Opium from the bruised capsules is not inflammable, and forms a turbid alcoholic solution. When gum arabic or tragacanth is used to adulterate it, the specimen forms, when rubbed with one part of alcohol and two of water, a tremulous gelatinous mixture.

It must be obvious that a substance of so complicated a nature cannot act uniformly on organised beings, even supposing them to be always constituted alike, which never is the case, since they vary according to age, constitution, habits of life, states of disease and idiosyncrasy, &c. Some of the effects which follow the employment of opium have been attributed to one prinicple and some to another; but, with a few exceptions, nothing positive has been ascertained. Morphia is by no means the only sedative principle; and narcotine, so long regarded as the stimulating principle, is, when pure, nearly if not quite inert. The odorous principle is unquestionably powerful, though it has no resemblance to hydrocyanic acid. The collectors of opium are generally pale and affected with tremblings. If opium be heated, the odour evolved is fatal to animals, and persons have fallen down in a state of insensibility from breathing an air charged with the vapour of opium in some pharmaceutical processes.

It is most probable that the extractive and resinous principles, with the meconic acid, which seems to modify the properties of the morphia, are the stimulating ingredients of opium, and that the getting rid of some or all of these, as in the watery extract of opium, and a few of the secret preparations of opium, constitute the superiority of these preparations, as calmants, over crude opium, or the officinal preparations in which they are retained.

A most extensive series of experiments have been instituted to determine the effects of opium: on vegetables by Marcet and Macaire; on animals by Charvet; and on man by numerous physiologists, including Charvet. From these it appears that opium acts as a poison to plants, by destroying their irritability. According to Charvet, in the case of the sensitive plant, where the opium failed to kill the subject of experiment, and it slowly recovered its irritability, yet the further growth was completely stopped. "In the animal kingdom, Charvet tried its effects on mammals, birds, reptiles, amphibia, fishes, insects (both in their perfect and larval states), the annelides, the mollusca, polypiphera, and polygastrica, and found that it acted on all as a poison, but with somewhat different effects according to their organisation. Thus on man it may produce congestion of the brain (marked by sopor and apoplectic symptoms), or irritation of the brain and spinal marrow (indicated by convulsions and pain), or a sedative effect (manifested by paralysis).

In other mammals, two kinds of effects are seen for the most part; the one of irritation, the other of diminished nervous power, symptoms of congestion being altogether wanting or very slight. This difference of effect corresponds with a difference in the development of the brain.

In the invertebrated animals, no symptoms of irritation seem to be caused by opium. This poison in them acts only on the contractile tissues, and produces symptoms of weakness or loss of contractile power.

In the animal series, the action of opium varies with the degree of development of the nervous system; and in the lowest orders the effects are quite analogous to those observed in vegetables. (Pereira.) (See Wilmer, 'Die Wirkung der Arzneimittel und Gifte in gesunden therischen Körper,' in which all the experiments are given in a classified arrangement.)

Much disputation has taken place respecting the question, whether opium be a stimulant or a sedative, and most unnecessarily, as its action depends, in general, on the quantity taken, the frequency of repetition, and the state of the system when it is administered. That to persons in health, if the dose be small, it is a stimulant, seems unquestionable; and this is proved by the fact that the habitual opium eaters consume it for the sake of its primarily stimulant effect, and not for the sake of the depression, languor, and suffering which succeed. The different degrees of action, resulting from a difference of dose, are so ably given by Dr. Pereira that they may be quoted here verbatim.

1. *First Degree of Operation.*—"In small doses, such as from a quarter of a grain to one grain, opium generally acts as a stimulant, though in this respect the symptoms are not uniform. Usually the vascular system is somewhat excited, and a sensation of fulness is experienced about the heart. The excitement in the cerebral vascular system is accompanied by alterations in the condition of the nervous functions. The mind is exhilarated, the ideas flow more quickly, a pleasurable or comfortable condition of the whole system is experienced, which is difficult to describe; there is a capability of greater exertion than usual. These symptoms are followed by a diminution of muscular power, and of susceptibility to the impression of external objects; a desire of repose is experienced, with a tendency to sleep. While these effects are taking place, the mouth and throat become dry, and hunger is diminished, though the thirst is increased; and slight constipation usually follows.

"Such are the common effects of a small dose of opium on persons unaccustomed to its use; but by repetition the influence of this agent becomes remarkably diminished, and those therefore who resort to it for the purpose of producing a pleasurable stimulus are obliged to increase the quantity in order to keep up an equal effect.

2. *Second Degree of Operation.*—"Given in a full medicinal dose, such as two or four grains, the stage of excitement is soon followed by that of depression. The pulse, which at first is increased in fulness and frequency, is afterwards reduced below the natural standard. The skin becomes hot, the mouth and throat dry, the appetite diminished, the thirst increased, and frequently nausea or even vomiting is induced. The symptoms of excitement soon pass away, and a state of torpor succeeds; the individual feels indisposed to exertion, the muscular system appears enfeebled, the force of impressions on the organs of the senses is diminished, and the ideas become confused. This state is followed by an almost irresistible desire to sleep, which is frequently attended by dreams, sometimes of a pleasing, at others of a frightful nature.

"These effects are usually succeeded by constipation (which may continue for several days), by nausea, furred tongue, headache, and listlessness."

3. *Third Degree of Operation; Poisonous Effects of Opium*, as given by Dr. Christison.—"The symptoms of poisoning with opium, when it is administered at once in a dangerous dose, begin with giddiness and stupor, generally without any previous stimulus. The stupor rapidly increasing, the person becomes motionless and insensible to external impression; he breathes very slowly, generally lies quite still, with the eyes shut and the pupils contracted; and the whole expression of the countenance is that of deep and perfect repose. As the poisoning advances, the features become ghastly, the pulse feeble and imperceptible, the muscles exceedingly relaxed, and, unless assistance is speedily procured, death ensues. If a person recovers, the stupor is succeeded by prolonged sleep, which commonly ends in twenty-four or thirty-six hours, and is followed by nausea, vomiting, giddiness, and loathing of food."

The quantity which can produce a fatal effect in a person unaccustomed to its use is very small, even four grains; and in children, owing to the large quantity of blood which naturally goes to the brain, and the great impressibility of their nervous system, a very minute portion of opium, or of its numerous preparations, open or disguised, can produce death. These facts constitute a strong reason for unskilful persons refraining from its employment, and also for avoiding in this place all details connected with its medical use. It is undoubtedly one of the most important means of alleviating human suffering when appropriately administered, and yet one of the greatest banes when abused. It is by the self-doctoring in general that the practice of opium-eating is acquired; and it is the more necessary to warn such persons against commencing the use of it, even for the legitimate purpose of overcoming disease, as they may inadvertently lapse into habits which they may never be able to shake off. Further, it should be known by those who are disposed to adopt this practice, that the habitual consumers of this drug have recourse to it again and again, not so much for the sake of the pleasurable sensations it can excite, as to *escape the misery*, mental and bodily, which their previous indulgence has entailed upon them. (Dr. Oppenheim's State of Medicine.')

It is necessary to place this statement before the public, as there is reason to believe that the practice of taking opium is becoming common in this country, where other stimulants are relinquished. Besides the injury done to the moral faculties and the general health, the quantity required to procure the desired excitement becomes at last so great as to render it a most expensive, and, to the poor, a ruinous habit. It has been alleged, in cases connected with life-insurance, that this habit has no tendency to shorten life. But the instances adduced in support of this view are quite inadequate to warrant such a conclusion, and all those demonstrating the longevity of opium-smokers in the East are altogether inapplicable. The effects of opium-smoking are by no means so pernicious as those of opium-eating. The preparation which the opium undergoes seems to disarm it of much of its injurious property. The Chinese employ only the soluble part of the opium after it has been half roasted, which they term smokeable extract, or *chandoo*, of which 50 or 51 per cent. is obtainable from Patna opium, and 70 to 75 per cent. from Malwa opium. This extract retains all the bitterness of the opium, but has not in the least degree the virose and nauseous odour which characterises crude opium. The more it has a brown colour, the milder and more agreeable is the odour. If well prepared, it resembles the taste of hazel-nuts. It is not mixed with tobacco, as some writers assert, and is smoked out of a very different kind of pipe,—one made of a cane of bamboo with two joints to it. The smoke is held in the mouth as long as possible, and then expelled through the nostrils. It is rarely swallowed, and if it should reach the stomach it generally causes some temporary disturbance of that organ. The Chinese use it both before and after meals, but if taken too soon after food it causes sickness. It seems to excite the bodily powers, but creates little derangement of the intellectual faculties, and does not occasion dreams, as opium-eating does. It appears to be an almost necessary stimulus in a climate where languor and listlessness so commonly prevail. Enjoyed in moderation it has no bad consequences. These statements are confirmed by the accounts of Dr Burnes ('Narrative of a Visit to the Court of Sinde,' p. 230), and above all, by that of Botta (Froriep's 'Notizen,' xxvi.), who made trial during a period of twelve months on himself, and found his general health in nowise affected. Strict philosophical inquiry must not be influenced by casual circumstances, and least of all should it be biassed by the rash assertions of those who debate the question of the effects of opium with the violence of partisans or the partiality of interested dealers. (See 'Quarterly Review,' vol. lxv., March, 1840, 'On Chinese Affairs,' written by Sir John Barrow.)

Of the treatment of a case of poisoning with opium, little need be added to what has been said under ANTIDOTES, and NARCOTICS. The first object is to empty the stomach, and as emetics can scarcely be made to act, the stomach pump should be assiduously used. The next object is to obviate the disposition to sleep. This may be done by keeping the person walking about as much as possible, and also applying cold and hot water alternately, as recommended by Dr. Boisragon ('Medical Gazette,' March 7, 1840), perseverance in which will often rescue the patient from imminent danger. When all the opium is removed from the stomach, vinegar, or coffee boiled in vinegar, may be drunk at short intervals. Moderate venesection (if the pulse be full) is sometimes of service, and carrying on artificial respiration is a most beneficial measure. The subsequent constipation requires attention.

A modification of Dr. Marshall Hall's plan of treating drowned persons, when no longer able to stand or walk about, would be useful. One point in this plan is to avoid laying the patient on his back, but, on the contrary, on his face, with his arms folded under his head, and moving him from side to side so as to cause successive expirations and inspirations, sixteen times in the minute only. (See 'The Lancet,' April 12, 1856.)

The officinal preparations of opium are numerous, and are fitted for different purposes. It is to be regretted that they are not of uniform strength, as this proves a source of inconvenience, as well as sometimes of danger. The great variation in strength of the tincture of opium, as found in the shops, has been pointed out by Dr. Christison ('Edin. Medical and Surgical Journal,' vol. xlix., p. 329), and even a greater difference is to be found in the syrup of poppies, which as generally prepared is a feeble preparation, but in other instances so powerful as to prove, in the dose of a few drops, fatal to children. (See 'Returns from the Coroners of England and Wales, of all Inquisitions held by them during the years 1837 and 1838, in cases where Death was found, by Verdict of Jury, to have been caused by Poison,' laid before parliament, on the motion of Sir Robert Inglis.) Numerous also are the instances of deaths from mothers and nurses administering nostrums, such as Godfrey's cordial and other soothing medicines, the most potent ingredient in which is opium. Paregoric elixir, though a weaker preparation than tincture of opium alone, or laudanum, differs much in strength in the two kingdoms. Scotch paregoric elixir is only one-fifth of the strength of laudanum, while English paregoric elixir is four times weaker. Some secret preparations in extensive use are, on the other hand, considerably stronger, such as the black drop, Battley's sedative liquor, and Jeremie's sedative solution, which last is now much employed in India, and even in Britain. It seems not to be followed by headache or constipation, effects so inconvenient that to avoid them the alkaloids of opium have been substituted for the crude drug. Thus acetate and hydrochlorate of morphia often agree with the system, where opium is unsuitable; and a syrup of codeia is efficacious against the gastric disorders of tropical climates, where opium or morphia even cannot be borne. ('Journal de Pharmacie,' tom. xxiii. p. 418; et tom. xxiv., p. 144.)

The capsules of the white poppy are ordered to be used to form an extract, and a decoction which is employed as a fomentation. These should be collected before they become ripe, as all the morphia is dissipated afterwards. The petals of the wild field poppy, *P. rhœas*, are used to form a syrup, which is only esteemed as a colouring material, and is not narcotic.

(Sachs, *Das Opium*, Königsberg, 1836; Charvet, *De l'Action comparée de l'Opium*; Christison, *On Poisons*; Pereira, in *Materia Medica*; and Holland, *Medical Notes and Reflections*.)

PAPAVERIC ACID. *Rhœadic Acid.*—An acid of doubtful existence, said to be contained in the flowers of the wild poppy.

PAPAVERINE. [OPIUM, ALKALOIDS OF.]

PAPER HANGINGS, a term applied (somewhat incorrectly) to the stained, or rather coloured, paper pasted against the walls of apartments, &c. The word "hangings" was originally and properly applied to the woven or embroidered tapestry with which the walls of rooms in mansions were covered. From the time necessary for their production, these were too costly for any classes but the wealthy. About 200 years ago, however, a mode was devised of printing or painting a pattern on sheets of paper, and pasting them against the walls of a room; these are "paper hangings," and they have greatly contributed to the comfort and cleanliness of domestic apartments. Before, however, actual *paper* hangings were adopted, there was a sort of intermediate plan by which textile material was employed. Jerome Lanyer, about the year 1638, produced what he called *tonture de laine*. This was cloth, on which a design was drawn in varnish or foot oil. A collection of *flock*, or powdered fragments of woollen, was at hand, different colours in different boxes; the flock was sprinkled on the cloth in a peculiar manner by the finger and thumb, and thus an attempt was made to imitate costly tapestries and brocades. When the cheaper material, paper, came to be employed, the device or pattern was printed in outline, with ink, on separate sheets of paper; the sheets were then joined edge to edge by paste, and the device was filled in by hand with distemper colour. The patterns were chiefly panels, containing groups of fruits, flowers, animals, small figures, grotesques, &c. About seventy years ago, there was a celebrated manufactory of paper-hangings at Chelsea, belonging to the Messrs. Echardts, where the best work was done. They employed many tasteful artists; they printed on silk and linen as well as paper; and the original blocks of some of their designs are still preserved.

As at present conducted, there are three modes of producing the required device. 1. Wooden blocks are carved, representing in relief the *outlines* of the figure; an impression is taken from these blocks, and the device is completed by painting with a pencil. 2. A sheet of paper, leather, tin, or copper, is cut out into the required device, and laid on the paper to be stained; a brush, dipped in a coloured pigment, and worked over the surface of the perforated plate, conveys the pigment through all the perforations, and forms a pattern on the paper. 3. A block is carved for each of the colours to be employed, and an impression from all the blocks in succession fills up the design on the paper. The first of these modes is too slow and costly for ordinary use; the second produces imperfect outlines, and is now chiefly employed (under the name of *stencilling*) to paint a pattern on the plaster walls of a room, without using paper-hangings; the third, which is the mode almost exclusively employed at the present day, we will now describe.

The paper is printed in pieces twelve yards long, and to produce these it was formerly necessary to paste sixteen or eighteen sheets of paper together at the edges. But machine-made paper now allows the paper stainer to procure the whole length in one piece. A piece is laid out on a long bench, and the ground-colour applied, consisting of pounded whiting tinted by the addition of some pigment, and liquefied by the aid of melted size; this is laid on with large brushes. When the paper is dry, it is ready to receive the print. Let us suppose the pattern to contain three colours,—red, dark green, and light green, besides the ground or general tint. Three blocks are carved in hard wood, the uncut parts (as in a common wood-block) representing the device; each block is intended for one colour only; and care is taken that all three shall register or combine their devices properly, when printed. The blocks are of pear-tree, mounted on pine. The three pigments being mixed with melted size, in separate vessels, one of them (say red) is spread with a brush on a wooden frame covered with leather or flannel: the proper block is laid face downwards on the wet paint, takes up a layer of it, and imparts it to the paper, on which it is immediately pressed. Another similar impression is made adjoining the first; and so on, till the whole piece has been printed with the red device. When dried, the paper goes through the same process a second time, with the substitution of a different colour and a different block from those before used. A third process with the other shade of green finishes the printing. Each block is furnished with small pins at the corners, by the aid of which the successive impressions are made to correspond properly. Numerous colours are sometimes employed in one pattern, and generally speaking there must be as many blocks as there are colours.

Such is the hand-method, very largely adopted. This manufacture, however, has shared in many of the advantages which mechanical ingenuity has conferred upon letter-press printing, by the adoption of the *cylinder*. About the year 1840, Messrs. Potter, of Darwen, introduced machine-printing into the trade. By means of steam-power, artificial drying, and an endless roll of paper, they were enabled to produce patterns with good effect for paper-hangings, by surface-roller printing in different colours. Year by year has this art improved, until at length some of the patterns are produced by as many as fourteen cylinders, each printing one particular colour. This number of colours has even been increased to twenty, by a peculiar management of the cylinders. The machines can now print 20,000 yards in a day each, if simple in device and colours. The immense extension of the paper-hanging manufacture within the last few years, and the lowering of price, are mainly owing to this use of steam-power cylinder-printing. All the best work, however, is still done by hand (as in book-printing and calico-printing).

Besides the more usual varieties of paper-hangings, there are many special kinds. Some have a glossy or *satin* ground. To produce this, a ground of satin white, properly tinted, is laid on; this ground is then rubbed with powdered French chalk worked by means of a brush, until a gloss is produced. After this the printing proceeds as usual.

These satin papers sometimes receive an additional beauty, by being passed between two slightly heated rollers, one of which has an engraved pattern in imitation of watered and figured silk, &c.: this pattern is thus imparted to the paper. *Flock* papers are those in which a portion of the pattern somewhat resembles woollen cloth. We have already spoken of these, as originally produced; but in the present mode of manufacture, when the proper ground-colour has been applied, the device is printed, not with a coloured pigment, but with japan gold-size; and on this gold-size is sprinkled the flock, consisting of fragments of woollen cloth cut into a sort of down and dyed. The flock adheres to the gold size and can easily be brushed off the other parts. Sometimes flocks of two or three colours are employed; these are laid on at separate times. The French have acquired much skill in the preparation of these flock papers: some of their *embossed* and *shaded* flocks are very beautiful. *Striped* papers are sometimes produced in a singular manner. The colour (rather more liquid than in other cases) is contained in a trough having parallel slits in the bottom. The paper is made to pass quickly under the bottom of the trough, by means of a revolving cylinder, and thus obtains a deposit of colour in parallel lines, through the slits in the bottom of the trough. By a modification of this method is produced what is termed a *blended* ground. A trough, containing many distinct cells, is filled with various tints of any given colour, one tint to each cell. A long narrow brush being dipped into all these cells, takes up a portion of each tint, which it applies to a roller; from the roller the pigment is transferred to a revolving brush, and from the brush to the paper. Thus is produced a blended or shaded ground, which afterwards receives any desired pattern. *Bronze* or imitation gold-powder is frequently applied to papers. A device being printed in japan gold-size, the powder is lightly rubbed over the paper, and adheres to the gold-size. The remainder of the pattern is commonly printed in colours. In some wall-papers, leaf-gold, silver, or copper is applied to a portion of the pattern: this is a slow and expensive process. Other kinds, again, in order to bear washing or cleaning, are printed with colours mixed with oil or varnish instead of size. A modern kind called *oak* paper is produced in a remarkable way; the grain is printed from a piece of real oak, and is thus more true to nature than any block engraved by hand; by shaving off a few fibres, a new pattern of grain can be developed at pleasure. Among various novelties in the manufacture, one relates to the printing of the pattern in a direction *transverse* to the direction of the paper, and pasting the paper horizontally on the wall; the intention seems to be, to diversify the effect, by removing a sameness resulting from the usual plan.

A matter of a remarkable and somewhat important nature has lately come under public notice, in connection with the use of arsenic in the colouring of paper-hangings. Certain tints of green are produced, more permanent than other kinds available to paper-stainers; and these permanent greens contain arsenic. When a committee of the House of Lords was collecting evidence on the "Sale of Poisons" bill, in 1857, Dr. A. S. Taylor brought forward this subject. He stated that arsenic is more largely used for these greens than in any other English manufacture; and that workmen, as well as the occupants of houses, suffered thereby. Constriction of the throat, nausea, head ache, loss of appetite, &c. result. Instances had come under his notice, as a physician, tending to prove that rooms, hung with paper coloured with arsenic greens, are very prejudicial to health. Another physician, Dr. Hinds, detected a minute trace of arsenic in loaves of bread which had been placed on the shelves of a newly-papered shop, the paper being brilliant with arsenic-green. A working paper-hanger informed Dr. Taylor that he always suffered from inflamed eyes and nose, sickness, and giddiness, on the days when he was engaged upon green papers. The Prussian government, attending to the cautions of physicians and chemists, forbid the use of arsenic in any colours, whether distemper, or oil, for indoor work.

With regard to the *patterns* of paper-hangings, we may remark, that the attention which has lately been given to the promotion of the arts of design will probably lead to much improvement in the devices for paper hangings, as well as for other ornamental productions. Mr. Owen Jones and other artists of distinguished ability, have supplied manufacturers with designs of a very superior character; but the great bulk of English designs are utterly inappropriate, and many, even when the paper-hangings are of an expensive kind, in extreme bad taste.

Sir Robert Peel made fiscal changes which greatly improved the paper hanging manufacture. There used to be an import duty of 1*s.* per square yard on foreign paper-hangings; this was nearly prohibitory, and the home manufacturers had not the stimulus of foreign competition; when the duty, however, was reduced to 1¾*d.*, elegant French papers came in, and taught a lesson. A further improvement was made by lessening the duty on paper itself from 3*d.* to 1½*d.* per lb., and by wholly repealing the extra duty of 1¾*d.* per square yard on paper hangings. Whatever may be said as to taste in fine art, it is certain that cleanliness and comfort have been promoted by these reforms; seeing that wall-papers can now be sold at so very low a price as to come within the reach of nearly all classes. At present, nothing beyond the paper-duty of 1½*d.* per lb. (plus 5 per cent.) presses on the trade; yet it has been recently shown that this 1½*d.* is, in many cases, more than as much as the paper-stainer receives for all his expenses, labour, machinery, anxiety, risk, and profit of every kind. He buys a ream of self-coloured or ground-coloured paper, weighing 300 lb., and containing 480 pieces of 12 yards each; he gives for it 5*l.* 15*s.*, of which 1*l.* 19*s.* 4*d.* is for excise duty. He prints and sells it wholesale for 6*l.* 17*s.* 6*d.*, or 3½*d.* per piece; and this price is made up of 1¾*d.* for paper, 1*d.* for duty, and ¾*d.* for colours, tools, labour, machinery, rent, skill, risk, and profit.

PAPER MANUFACTURE AND TRADE. In early times the materials used for writing upon were chiefly such as only required some little mechanical fashioning to fit them for that purpose. Characters were engraved on flat stones made smooth, or were impressed in clay, which was afterwards dried and hardened by sun or fire, as in the case of the Babylonian bricks. Thin boards of wood covered with wax or some similar composition, and plates of ivory and of metal, have often been used. A more convenient material was afforded by the leaves of some species of trees. The skins and intestines of animals have also been made fit for writing upon; but wherever the Egyptian papyrus was introduced, all these things fell into disuse, except parchment, which is still preferred for certain purposes. [PARCHMENT; PAPYRUS.]

Paper Manufacture.—The art of making paper from fibrous matter reduced to a pulp in water appears to have been first discovered by the Chinese about the year 95 A.D. In the time of Confucius they wrote with a style, or bodkin, on the inner bark of the bamboo. The Chinese paper has been supposed to be made of silk; but this is a mistake. Silk by itself cannot be reduced to a pulp suitable for making paper. Refuse silk is indeed occasionally used with other things; but the greatest part of the Chinese paper is made from the inner bark of the bamboo and some other trees. The Chinese also make paper from cotton and linen rags; and a coarse yellow sort for wrappers is made from rice-straw. Only the second skin of the bark of the bamboo is used, which is beaten into a pulp with water. The Chinese can make sheets of a large size: the mould on which the pulp is made into paper being sometimes ten or twelve feet long, and very wide, and managed by means of pulleys. It is formed of fine threads of bamboo, as ours are of wire. To prevent the ink from running, the sheets are dipped into a solution of alum, which, as their ink is thicker than ours, is generally sufficient for the purpose, but sometimes fish-glue is mixed with the solution of alum. (Du Halde's 'China,' vol. ii., p. 415; Davis's 'Chinese,' chap. xvii.)

The Arabians, in the 7th century, appear either to have discovered, or to have learned from the Chinese, the art of making paper from cotton. They seem to have carried the art to Spain, and to have there made paper from linen and hemp as well as from cotton. ('Journal of Education,' No. 10.)

So far as concerns our own country, a manufacturer named Tate had a paper-mill at Hertford early in the 16th century; and another mill was established in 1588 at Dartford in Kent, by John Spelman, who was knighted by queen Elizabeth. Previously to this, and for some time afterwards, our principal supplies were from France and Holland. The making of paper in England had made little progress even so late as 1662. Fuller has the following remarks respecting the paper of his time:—"Paper participates in some sort of the character of the country which makes it; the Venetian being neat, subtle, and court-like; the French, light, slight, and slender; and the Dutch, thick, corpulent, and gross, sucking up the ink with the sponginess thereof." He complains that the making of paper was not sufficiently encouraged, "considering the vast sums of money expended in our land for paper out of Italy, France, and Germany, which might be lessened were it made in our nation." Thomas Watson, a stationer, by the introduction of foreign improvements in 1713, gave a great impulse to the manufacture of paper. Still, notwithstanding the great increase of demand and application of capital, it was much retarded by the heavy duty, of which we shall have to speak presently. So late as the middle of the last century, only very common paper, principally for wrapping, was made in Great Britain. It was not until 1770 that the celebrated Whatman introduced fine-paper making at his mill at Maidstone.

In the making of paper, any fibrous vegetable substance may be used: such as the inner bark of trees, the stalks of the nettle, the tendrils of the vine, the bine of the hop, wheat straw, flax straw, &c. Nothing however has yet been found to answer so well as linen, hempen, or cotton rags. The sweepings of the cotton-mills are also much used. Woollen cloth is not fit for the purpose, because it cannot be beaten into a suitable pulp, and also because it gives a hairy texture to the surface. Linen rags are the best of all for the purpose. The rags, however, of our own country do not constitute a fourth part of the quantity which we use in making paper. Italy and Germany furnish the principal supplies. They are imported in bags of about 4 cwts., each bag being marked in such a manner as to indicate the quality of the rags which it contains.

In every paper-mill the first business is to sort the rags and cut them into small pieces. This is done by women, each of whom is provided with a large knife to cut the rags. Threads and seams are carefully put by themselves: if ground with the cloth, they would form specks in the paper. The rags, when cut, are thrown in to five or six different compartments of a large chest, according to their qualities. Only the finest linen rags are used for the best writing-paper, but cotton as well as linen rags are now used for printing-paper.

A good workwoman can sort and cut about a hundredweight a day. Hempen rags are used for coarse papers, and old cordage and tarred ropes for brown wrapping-papers.

The rags are now to be washed, which is done either with hot water in a fulling-mill, such as is used for scouring cloth, or they are subjected for some hours to the action of steam. Formerly they were half rotted to prepare them for being more easily torn and beaten into a pulp. But by this process the fibre was partially destroyed, and the texture of the paper materially injured.

Previous to the important discovery that chlorine possesses the property of destroying all vegetable colours paper-makers could only bleach their rags by subjecting them to various washings in alkaline leys, and by exposing them to the dew and light; and after all their pains they only obtained a paper so imperfectly white that they were obliged to mask the defect by tinging it with a shade of blue. But now, by the proper application of chlorine, either in the form of the simple gas or in combination with lime (chloride of lime), the colour can be perfectly discharged, and the paper rendered, if necessary, of the purest white. Objections have been justly made to the improper application of chlorine in bleaching paper. Sometimes it is applied in such quantity, or for such a time, as to injure the substance of the fibre; sometimes the paper, after it is made, is bleached with chlorine in such a manner that the ink turns brown; and there have been instances in which the colour has been nearly discharged altogether, leaving the sheet almost as it was before it was written or printed upon. It is now, however, generally admitted that chlorine, judiciously applied, is not in the smallest degree injurious to the paper, or liable, in any length of time, to alter the colour of the ink; although there is unquestionable proof that, unless skilfully managed, bleaching leaves the fibres less coherent than they were before.

The rags, after being washed, are subjected to the action of a revolving cylinder, the surface of which is furnished with a number of sharp teeth or cutters, so placed as to act against other cutters fixed beneath the cylinder. The rags are kept immersed in water, and subjected to the action of the cutters for several hours till they are minutely divided and reduced to a thin pulp. During this process a quantity of the chloride of lime or of chlorine gas is mixed with the rags, by which the pulp is rendered perfectly white. Until about a century ago, the rags were always pulped by means of stampers; but cutting-machines, introduced by the Dutch, greatly expedited the process.

The pulp, or *stuff*, as it is technically called, is now ready to be made into paper, which is done either by hand or by machine. On the hand-method, the stuff is put into a large vat, and is kept at a proper temperature either by a stove or by steam-heat; and the fibrous matter is held in suspension by a continual motion carried on in the vat by means of what is technically called a *hog*, or by other improved apparatus.

The paper is made with a *mould* and *deckle*. The mould is a shallow square frame covered with wire cloth, and a little larger than the sheet intended to be made upon it. The wire-cloth is now generally woven in a loom like cloth, and makes no wire-marks on the paper; but the old fashioned wire-cloth consists of a number of parallel wires stretched across the frame, very close together, and crossed at right angles by other stronger wires about an inch apart. These thicker wires make the *wire-marks* of the paper, the stuff being there thinner than on the rest of the sheet. It was Baskerville who introduced the woven-wire moulds, in 1750; or rather, a beautiful edition of 'Virgil,' printed by him on paper thus made, was the means of drawing general attention to this improvement. The deckle is a very thin frame of wood which fits close upon the mould, and is required to retain the stuff on the mould and to limit the size of the sheet. The *dipper*, or *vatman*, inclining the mould a little towards him, dips it into the vat with the deckle upon it, and lifts it up again horizontally. He shakes it to distribute the stuff equally, and the water drains through the wire. He lays the mould on the edge of the vat, and takes off the deckle, which he requires to apply to another mould. After remaining two or three seconds to drain, the mould is taken by another workman, the *coucher*, who, having deposited the layer of pulp upon a felt, or piece of woollen cloth, returns the mould to the dipper, who in the meantime has made another sheet, which stands on the vat ready to be couched upon another felt spread over the former sheet. Thus the two workmen proceed till they have made a pile of sheets, called a *post*, consisting of six or eight quires. This post, with its felt, is placed in the *vat-press*, and subjected to a strong pressure to force out the superfluous water, and to give firmness and solidity to the paper. The pile is then removed from the vat-press, the felts are taken out, and the sheets pressed again by themselves. They are then taken from the press, and hung up, five or six together, in the drying-room.

The paper is now made, and only requires finishing. The greater number of the finishing processes are only required for writing-paper: common printing paper and wrapping papers being ready for packing up when dried. Writing-paper is dipped, five or six sheets together, into a tub of size, and afterwards pressed to force out the superfluity. It is then hung up again in the drying room. Printing-paper is sized in the stuff. Every sheet is examined, imperfections are removed, and bad sheets taken out. A large pile of paper is then made, and pressed with great force to render the sheets quite flat and smooth. The pile is next taken down sheet by sheet, and another made, by which new surfaces are brought into contact with each other; and the pile is again pressed strongly. This operation, which is called *parting*, is done two or three times for the best papers. The paper is now counted into quires, folded, and packed up into reams. The size is made from skins and other animal substances, and is required to prevent the ink from spreading among the fibres by capillary attraction. Blotting-paper is not sized.

We now proceed to notice the machine-method of making paper—without which, the extension of cheap literature, and the wonderful development of the newspaper system, would have been almost impossible; printing-machines would possess insufficient material to print upon, had not paper making machines kept pace with them. The history of these last named machines is briefly as follows. Just at the close of the last century, M. Robert, a workman in the employ of M. François Didot, at a paper-mill at Essones, in France, invented a machine for making continuous paper; Didot set the apparatus to work; and Robert obtained 8000 francs from the government, and a patent for fifteen years. This was in 1799. In 1801 Didot came over to England, accompanied by Mr. John Gamble, who had resided some time in France. After sundry negociations, and the obtaining of two English patents, these patents were sold to Messrs. Fourdrinier. Messrs. Hall's establishment at Dartford, in Kent, was selected as the place for making the machines, under the special care of Mr. Bryan Donkin. It was in 1803 that the model of the first self-acting machine was set up at Frogmore, in Hertfordshire; and in 1804 that the system came successfully into work at a paper-mill at Two Waters. Since that year, a succession of beautiful additions and improvements have been made; although it is only just to mention that the main principles of the machine have all along remained nearly the same. Messrs. Bryan Donkin & Co. have devoted such special attention to this subject, that they have throughout been the chief makers of the machines: in the first ten years they set up 18 paper-machines; in the next ten, 25; by the year 1851 they had set up 191; and the number has since steadily increased. So far from these having all been intended for home use, more than half were made for foreign manufacturers: Germany being the best customer on the continent of Europe. It is proper to state that some of the matters connected with the early history of the paper-machine, both as to honour and profit, are still in dispute; and that so late as 1857, Mr. John Gamble, in a communication to the Society of Arts, protested against the way in which his name is generally omitted from among those who deserve credit or fame as introducers of the paper-machine. It is not often that an inventor, or the fosterer of an invention, lives to put in such a claim fifty-six years after the occurrences to which the claim relates.

We shall now briefly describe the operation of the paper-machine. The machine is constructed in such a manner as to imitate, and in some respects to improve, the processes used in making paper by hand; but its chief advantages are, that paper can be made of any size that can practically be required, and with a degree of rapidity which leaves the other mode of making it at an immeasurable distance. The pulp is first made to flow from the vat upon a wire frame, or sifter, which moves rapidly up and down so as to force the fine filaments of the pulp through the wire, whilst it retains any knots or other unsuitable matter. Having passed through the sifter, the pulp flows over a ledge in a regular and even stream, and is received upon an endless web of wire-gauze, which presents an uninterrupted surface several feet long. The wire-web moves forward with a motion so regulated as, taken in connection with the quantity of pulp allowed to flow upon it, to determine the thickness of the paper. At the same time a shaking motion is given from side to side, to the wire web, which assists in spreading the pulp evenly, and also in facilitating the separation of the water, which passes through the wire; by this means the pulp solidifies as it advances, and is at the same time prevented from flowing over the sides by straps which regulate the width of the paper. Before the pulp, now no longer fluid, quits the plane of wire, it is pressed by a roller covered with felt. It is next taken up by an endless web of felt, which forms an inclined plane, and gradually moving forward absorbs a further portion of the moisture. The pulp is now seized by a pair of rollers, between which it is pressed; and then it passes upon another inclined plane of felt, which conducts it to another pair of pressing rollers. The pulp is at length paper, and only requires to be made dry and smooth. To effect these objects, the machinery conducts it over the polished surface of a large cylinder heated by steam. From this cylinder it passes to a second, larger and hotter, and then to a third, which is still hotter than the second. After this it is subjected to the pressure of a woollen cloth, which confines it on one side while the cylinder smooths it on the other. It is then conducted by another roller to a reel, on which it is wound, perfectly dry and smooth, and ready to be cut into sheets for use. In two or three minutes the pulp, which is introduced upon the wire web at one extremity of the machine, is delivered at the other in the state of perfect paper. In printing-paper the size is commonly added to the pulp; but writing-paper is sized after the sheets are cut, as in hand-made paper.

In most of the paper-making machines a partial vacuum is produced under the endless wire-web by means of large air-pumps. The atmosphere is thus made to press upon the pulp, and the moisture is forced through the wire. Owing, however, to the change of stroke of the pistons, a uniform degree of vacuum cannot be maintained, so that the pulp receives various degrees of pressure, and consequently the paper is made of unequal thickness. To remedy this defect, by rendering the vacuum as uniform as possible, two patents were taken out in 1839; one to effect the purpose by substituting a revolving fan for the air-pump, and the other by using hydraulic air-pumps working on the principle of gas-holders, instead of the common ones.

Various patents have been taken out for improvements in parts of the machinery, or for other machinery to be applied in various stages of the process. One was taken out by Mr. Dickinson for an apparatus to separate the knots and lumps from the pulp, by making the pulp pass through the periphery of a revolving cylinder constructed of an endless spiral wire attached to metal bars. Other improved processes for the same purpose have been invented. A patent was taken out by Messrs. Towgood and Smith, the object of which is to apply the size to the paper as it comes in a continuous sheet upon the endless wire-web. The operation in this apparatus is performed by rollers, the surfaces of which are supplied with size, which is transferred from them to the newly-made paper as it passes between the rollers. Mr. Dickinson has a patent for uniting two layers of pulp in order to produce paper of an extra thickness. The combination of two or more sheets of pulp has been long employed in the making of thick drawing-paper and Bristol-board by the process called couching; but Mr. Dickinson's contrivance affords the means of doing it in a common paper-making machine. No attempt, however, can be made here to enumerate in detail the steps by which improvements have been introduced in the paper-machine; they are too numerous. Foreign inventors have done much in this matter. The names of Robert and Didot have already been mentioned; and we may also notice M. Canson, who was the first to apply suction-pumps to the machines; and M. Jequier, who devised a mode of making continuous paper with wire marks. Among English paper makers and machinists, the names of Brown, Crompton, Taylor, Barrett, Ibotson, Wilks, and Hollingworth may be mentioned as the introducers of valuable improvements in the continuous paper making. So wonderful is now the operation of the machine, that fine writing-paper can be made, sized with gelatine, dried, and cut into sheets, at the rate of 60 feet a minute in length, and 70 inches in width.

Varieties of Paper.—We shall now notice a few matters connected with the differences in the kinds of paper, without particular reference to the fact of their being hand-made or machine-made.

It may here be observed, that various wire-marks, or water-marks, as they are called, were formerly applied to paper to distinguish it. On the paper used by Caxton and the other early printers these marks consisted of an ox-head and star, a collared dog's head, a crown, a shield, a jug, &c. A head with a fool's cap and bells gave name to the paper called foolscap; and post paper seems to have derived its name from the mark of a horn, which was formerly carried by the postman, and blown to announce his arrival. Hand-made paper is now commonly marked with the name of the maker, and the date of the year when it was made.

The cutting of paper into sheets of any desired size is an operation which has been greatly improved within the last few years. The best paper is examined when made, to remove knots or specks, and to lay aside damaged sheets. It is then counted into *quires* of 24 sheets, folded, and put up into *reams* of 20 quires. If the paper is for printing, the continuous web made at the machine is cut into sheets of a certain size, without any particular regard to the fineness of the cut; but in the preparation of writing-paper, whether hand-made or machine-made, the cutting is very carefully attended to. Hence there are cutting-machines of two different classes, one to sever the web into sheets, and one to cut well-squared sheets of writing-paper. In the first of these kinds the paper is generally coiled round a cylinder into a substantial mass, and this cylinder, while rotating, is brought at intervals against a cutting edge in such a way as to cut through the paper. In the second kind much ingenuity has been shown; and it is certain that the remarkable cheapening of writing-paper since the introduction of the penny post has been greatly due to the adoption of machines, instead of hand-cutting, for the severance of the paper into sheets. In Black's paper-cutting machine, a sharp knife fixed to a rack is made to traverse laterally by the motion of the rack. The paper is laid upon a bed, and is adjusted by a screw spindle. A back-plate is hinged at its lower edge, so as to be brought by pinching-screws to a proper position for the paper to be cut rectangularly; and there is a screw to raise and lower the knife. Morgan's cutting-machine is intended to do the work with a small expenditure of power; the cutting-knife rotates on an axis, and the paper advances horizontally to meet it, like the action of a circular saw in timber cutting. In Ullmer's machine there is a contrivance for imparting to the cutting-knife a diagonal movement, so as to enable it to make a draw-cut in an effective manner. There are many other paper-cutting machines, acting on similar principles, but differing in details.

Mr. Herring, in a recent work on the paper manufacture, while giving a list of the various sizes and names of paper, puts together the writing, drawing, printing, and wrapping papers, and then separates them simply into two groups, according as they are fine or coarse. The chief names and sizes mentioned by him are as follow:—

FINE PAPERS.

	Inches.		Inches.
Pot	15 by 12½	Printing demy	22½ by 17¾
Foolscap	17 „ 13½	Medium	22 „ 17½
Post	18¾ „ 15¼	Printing medium	23 „ 18½
Copy	20 „ 16	Royal	24 „ 19
Large post	20¾ „ 16½	Printing royal	25 „ 20
Medium post	23 „ 18	Super royal	27 „ 19
Sheet-and-third foolscap	23 „ 13½	Printing super royal	27 „ 21
Sheet-and-half foolscap	24½ „ 13¼	Imperial	30 „ 22

So numerous, however, are the sizes, thicknesses, and qualities of the various kinds of paper, cardboard, millboard, &c., that some of the largest wholesale dealers, according to Mr. Herring, keep in stock not much less than *two thousand* different kinds. Placing them under a few headings, without regard to size, papers are sometimes designated thus:—*Writing* paper, five kinds, namely, cream wove, yellow wove, blue wove, cream laid, and blue laid; *printing* paper, two kinds, namely, laid and wove; *wrapping* paper, four kinds, namely, blue, purple, brown, and whited-brown. In these various kinds of paper it is believed that England takes the lead of the Continent, except in two particulars: that *thin* French writing-paper is better than English; and that the French obtain a purer surface than the English, who often hide a dirty white by blueing it.

A few years ago careful experiments were made to determine the relative strengths of different kinds of paper; and the result was given in the last edition of the 'Encyclopædia Britannica.' In the following table the first column shows the kinds of the paper; the second, the weight in grains of a superficial foot; and the third, the weight in pounds upheld without breaking by a strip two inches broad:—

Bank post, very thin, sized	65 grains.	23 lbs.
„ thinner, unsized	48 „	13 „
Thick writing, machine-made	139 „	42 „
„ hand-made	143 „	60 „
Drawing paper, machine-made	217 „	55 „
Newspaper, sized at machine	113 „	39 „
Scotch bank-note paper	95 „	70 „
Strong cartridge paper	135 „	64 „
Pink blotting-paper	90 „	10 „

Among the varieties in paper-making may be mentioned Dickinson's double-faced paper, to be used either for lithographic or copper-plate printing, according as one or the other surface is selected; two webs of different kinds of pulp are placed one on another, and are pressed so as to unite them into a single sheet. *Laced* paper is now very much employed. The French have long made it, and applied it to ornamenting fruit-baskets, lamp-shades, print-borders, &c. About 1830, M. Rivière, a Swiss watchmaker established in London, obtained a patent for perforating thin metal plates; Messrs. De la Rue contrived a modification of the same apparatus for perforating pasteboard and card; and hence has arisen an extensive branch of ornamental paper-making, especially for *valentines*, the production of which is enormous. Plain-surface coloured papers are now largely made, for the use of bookbinders, printers, button-makers, confectioners, &c. The colour is applied by means of brushes, similar to those employed by paper-stainers; but the pigments are better, and more care is taken in laying on, smoothing, and finishing. Gilt, silvered, and coloured papers are prepared for decorative stationery, by chromo-lithography, surface-printing, block-printing, and woven-wire printing. The ingenuity of paper-makers has also been directed to the production of paper covered with real gold and siver; paper coated with bronze or imitation bronze; paper embossed and grained by means of engraved rollers, dies, and plates; paper varnished to imitate Morocco leather; paper enamelled, for the ground of fine satin paper-hangings, and for other ornamental purposes, by treating the surface with sulphate of barytes—a pigment reduced in price within a few years from 21*s.* to 6*d.* per lb.; paper extra-enamelled with Kremnitz white lead, for wedding-cards, &c.; paper with an opaline iridescence, prepared by Messrs. De la Rue; paper to which a kind of metallic granular surface has been given, for memorandum books; &c.

Much attention has been paid to the manufacture of paper which may frustrate the designs of forgers. The selection of a device or design for bank-notes, cheques, &c., the mode of engraving, the mode of printing, and the kind of ink, all bear immediately on this subject. The principle is this—to apply to the paper such a chemical agent that, if the ink be tampered with, the paper shall become discoloured and the attempt at fraud revealed. Mr. Stone, Mr. Barclay, Mr. Stevenson, Mr. Herapath, and other persons, have directed their attention to this matter; and the chemicals suggested for application are prussiate of potash, iodide and ferrocyanide of the same alkali, salts of copper, salts of manganese, starch, &c. One recipe is, for a ream of post, 1 oz. of iodide of potash, ½ oz. of ferrocyanide of potash, and 1 lb. of starch. Any attempt to remove writing by chemical agents from paper thus treated would damage the colour of the paper itself. A paper has been read and a discussion has taken place on this subject before the Society of Arts during the present year (1860).

Of the practical applications of paper little need be said: these are for the most part sufficiently obvious. The amateur arts of papyrography, papyro-plastics, potichomanie, &c., are little more than ingenious modes of cutting out sheets of paper. We may mention, however, the bituminised paper tubes made by M. Jaloureau. He finds that when bitumen is mixed with chalk, and paper tubes are saturated with it, they become remarkably strong and durable, and are available as water-pipes.

Materials for Paper.—A little attention must now be paid to the subject of the *materials* for paper, concerning which the manufacturers have lately had many discussions. Repeated attempts have been made to manufacture paper from straw, but it is only recently that any success has been obtained. One mill in the United States now makes 30 tons of this paper weekly. Wheat-straw is put into a large spherical boiler, and there boiled for 24 hours at 320° Fahr., a temperature obtained under great pressure. The straw becomes converted into a glutinous mass, which by further processes is available as pulp for paper. Dr Collyer, in April, 1860, communicated to the Society of Arts the result of an elaborate series of experiments on the manufacture of paper from straw. He was led by his researches to recommend the following processes:—The straw is first passed between two rollers rotating with different velocities; this produces a trituratory action, which rubs out the knots and ears, and at the same time opens the straw out to a partially fibrous state. The straw is then exposed to the action of water heated by steam, and containing 3 ozs. of caustic alkali to the gallon. The apparatus is so arranged that the alkaline liquor can act over and over again upon the straw; and by repeated workings after this steeping, nearly all the gluten and silica are removed from the straw. The bleaching is effected by chloride of lime, with superheated steam. The making into pulp then ensues, and the manufacture proceeds as with rags. These operations, however, are quite tentative. All the straw paper hitherto made is unpleasantly crisp and brittle; and it has been found that the price of straw goes up considerably whenever the paper-makers create a demand for it. Nevertheless, two or three of the penny daily newspapers are printed on straw paper, and the experiment is felt to be worthy of further investigation.

Another kind of paper is Schlesinger's, manufactured of wood. Timber is cut by machinery into logs about eight inches in length. These logs are made to press against a rotating grindstone made of very rough stone, and well moistened with water. The wood is rubbed off in a state of fibrous pulp, which, either used by itself, or mixed in certain proportions with rags, is converted into paper. A mill for the manufacture of paper of this kind was opened at Bradford in 1854, the paper produced being chiefly wrapping, packing, cartridge, and other coarse kinds. The wood pulp is said to be obtainable at about 1*d*. per pound.

The increasing importance of obtaining a supply of rags for paper-making, and the restrictions placed by foreign governments on the sale of such rags to England, have lately recalled attention to projects long ago entertained. It is said that no less than 45,000 tons of linen rags, all collected by the *chiffoniers*, or itinerant ragmen, were used in France in 1859 in paper-making; and the paper-manufacturers of that country strenuously oppose any plan which might lead to an increased sale to England. Nearly all vegetable fibrous substances, as was observed in a former paragraph, can be converted into paper; but the problem is, whether such paper would be fine enough, strong enough, and cheap enough to compete with rag-paper. The so-called Chinese rice-paper consists of thin films cut spirally from the branches of a particular tree, the *Æschynomene paludosa*. There is in the British Museum a curious book, prepared by Jacob Christian Schaffer, a native of Ratisbon, about the year 1775. It describes the manufacture of paper from different substances, and the sixty leaves of which the book is composed are made of sixty different kinds of paper. The bark of the willow, beech, aspen, hawthorn, linden, and mulberry; the down of the catkins of the black poplar, and the silky down of the asclepias; the tendrils of the vine, the stalks of nettle, mugwort, and dyers'-weed; various kinds of leaf, fibre, and stalk; as well as straw, seeds, moss, lichens, wood shavings, sawdust, potatoes, and fir-cones—all were employed. The paper is in all the specimens of very inferior quality, both in colour and texture, but unquestionably the same materials would yield better results, if treated with modern skill and appliances. In 1854 the proprietors of one of our great newspapers offered a prize of 1000*l*. to the discoverer or inventor of any new kind of paper which, at a certain wholesale price, should possess a certain list of good qualities; but the desired standard has, we believe, never yet been reached. In the same year, the Treasury drew the attention of the Board of Trade to the scarcity in the materials for paper; and suggested that, in conjunction with the Foreign Office, the Board might possibly be able to obtain from British consuls abroad, useful information concerning vegetable fibre which would be available for this manufacture. It was mentioned that 2*d*. or 2½*d*. per pound might perhaps be the price which paper manufacturers would be willing to give for such materials. r. Lyon Playfair, on the part of the Board of Trade, stated that, after conferring with many eminent manufacturers, he had arrived at a conclusion that any new material must be obtainable at 1*d*. or 1½*d*. per pound, in order fairly to meet all the requirements. Much valuable information has since been obtained from British consuls abroad, and especially from Dr. Forbes Royle and Dr. Hooker, concerning fibrous plants in various parts of the world; and there is reason to hope that these researches will ultimately lead to beneficial results. In 1859 an attempt was made to establish a manufacture of paper from flax-straw and flax refuse, by means of a joint stock company, on the basis of a patent obtained by Mr. Houghton. Whether or not the process is a good one, the company itself has, we believe, not yet actually been formed.

Paper trade and duty.—Until 1837 the duty on paper was charged in two classes. That made whole out of old tarred rope, without extracting the pitch or tar, was considered as second-class paper, and paid only a duty of 1½*d*. per lb.; while paper made of any other materials was considered as first-class paper, and was charged with a duty of 3*d*. per lb. In the year above mentioned this distinction was abolished, and the duty on all kinds of paper was fixed at 1½*d*. per lb., which gave an immediate impulse to the trade. The effect of this change in augmenting the quantity used was soon shown. In round numbers, the quantity made in 1835 and 1836 averaged 78 million lbs. a year, whereas in 1837 and 1838 it averaged 91 million lbs. Foreign paper had not hitherto competed largely with home-made because a Customs' duty had interfered with it. In 1857 and the two following years, the quantity of paper made in the United Kingdom was about 198, 193, and 218 million lbs. respectively; of which about one-twelfth was exported, and eleven-twelfths used at home. The average quantity made at each mill may be inferred from the following table, applicable to the year 1859:—

England .	694	paper mills, of which	333	were at work in 1859.
Scotland . .	79		54	
Ireland .	70		27	
	843		414	

Kent is the head-quarters of the manufacture; after which Hertfordshire and the neighbouring counties, Lancashire, and Devonshire. In Scotland, Lanark, Midlothian, and Aberdeen are the chief paper-making counties.

Few public subjects have been more discussed within the last few years than the propriety of removing the excise duty on paper. This duty, of 1½*d*. per lb. plus 5 per cent., after a few drawbacks for exportation, &c., yielded about a million and a quarter sterling of net revenue annually to the state; and Chancellors of the Exchequer, however favourable to the diffusion of cheap literature, have been unwilling to part with this easily collected tax. In 1853, the Society of Arts drew up a list of queries, and sent them to paper-manufacturers, wholesale stationers, manufacturers of paper articles, publishers, newspaper proprietors, and authors, soliciting opinions as to the modes in which the paper duty affected various branches of the public. Some of these queries were—Does the mode in which the duty is collected interfere injuriously with the process of manufacture, and in what way? Does it affect the quality and variety of the article manufactured? Does it limit materially the quantity of the supply? Do the excise regulations interfere with the rapid execution of orders? Does the mode of collection prevent the use of new materials? Does it place the manufacturer at a disadvantage in the market? Much valuable information was obtained in response to these queries. During the subsequent period of seven years (1854 to 1860 inclusive) great activity had been shown in the advocacy of the abolition of the duty, by various bodies, and through the medium of various publications. It is not now necessary to adduce the arguments used; for the tax is on nearly all sides admitted to be a bad one. In the session of 1860, Mr. Gladstone, as Chancellor of the Exchequer, moved the abolition of the duty, in connection with a very extensive financial scheme, including a commercial treaty with France, and a removal of Customs' duties from many minor articles. The bill for the abolition of the paper duty was passed by the House of Commons, but rejected by the House of Lords. The Customs' duty on foreign paper of 2½*d* per lb., with 5 per cent. additional, has, however, been reduced to 1½*d*. per lb. with 5 per cent. additional, the same rate as the excise duty on the home manufacture, so that the importation is now unimpeded.

PAPIER-MÂCHÉ, the French term for a preparation of moistened paper, of which many articles are manufactured in England, France, and Germany. Such articles have been made in France for more than a century. In 1740 one Martin, a German varnisher, went to Paris to learn this manufacture from Lefevre. On returning to his own country, he was so successful in his exertions that his paper snuff-boxes were called, after him, "Martins." So much money went from Prussia to France in purchase of papier-mâché articles, that Frederic II., in 1765, established a manufactory at Berlin, which soon became very successful. Brunswick, Nürnberg, Vienna, and other German towns, by degrees commenced the manufacture, and it is now carried on to a considerable extent.

Two modes are adopted of making articles of this kind: 1, By glueing or pasting different thicknesses of paper together; 2, By mixing the substance of the paper into a pulp and pressing it into moulds. The first mode is adopted principally for those articles, such as trays, &c., in which a tolerably plain and flat surface is to be produced. Common millboard, such as forms the covers of books, may convey some idea of this sort of manufacture. Sheets of strong paper are glued together, and then so powerfully pressed that the different strata of paper become as one. Slight curvatures may be given to such pasteboard when damp, by the use of presses and moulds. Some of the snuff-boxes are made by glueing pieces of paper, cut to the sizes of the top, bottom, and sides, one on another, round a frame or mould, which is afterwards removed. Articles made of pasteboard have often a fine black polish imparted to them in the following manner: After being coated with a mixture of size and lampblack, they receive a coating of a peculiar varnish. Turpentine is boiled down till it becomes black, and three times as much amber in fine powder is sprinkled into it, with the addition of a little spirit or oil of turpentine. When the amber is melted, some sarcocolla and some more spirit of turpentine are added, and the whole is well stirred. After being strained, this varnish is mixed with ivory-black, and applied in a hot room on the papier-mâché articles, which are then placed in a heated oven. Two or three coatings of the black varnish will produce a durable and glossy surface impervious to water. Some of the articles now made in this way have their surfaces inlaid with mother-of-pearl; the shell is fastened down to the surface as a veneer, an immense body of varnish is laid on, and by rubbing the superfluous varnish from the pearl, the whole is brought to one common level, presenting a brilliant if not always tasteful effect. The better kind of tea-trays are shaped in or rather on iron moulds, the top of the mould giving the shape of the tray. The paper employed is a grayish, thick, granulated kind, made expressly for the purpose. The mould and paper are taken to a heated stove-room to dry, after three thicknesses have been applied, and this removal is repeated from ten to forty times, for the trays are made of thicknesses of paper varying from thirty to a hundred and twenty. The surface of the mould is greased in the first instance, to ensure the easy removal of the papier-mâché when of the proper thickness. A patent was taken out a few years ago for making papier-mâché panels for carriages, and considerable skill has been shown in the manufacture; but such panels are not much used in England, owing in part to the operation of the paper-duty.

The second kind of papier-mâché is, however, the more extensively made. It comprises that which is pressed into moulds in the state of a pulp. This pulp is generally made of cuttings of coarse paper boiled in water, and beaten in a mortar till they assume the consistence of a paste, which is boiled in a solution of gum-arabic or of size to give it tenacity. The moulds are carved in the usual way, and the pulp poured into them, a counter mould being employed to make the cast nothing more than a crest or shell, as in plaster casts. In some manufactories, instead of using cuttings of made paper, the pulp employed by the paper-maker is, after some further treatment, poured into the moulds to produce papier-mâché ornaments. The use of ornaments made in the way just described is rapidly increasing. The carved and composition ornaments employed to decorate picture- and looking-glass frames are in some cases superseded by those of papier-mâché; but it is in the decoration of ceilings and walls of rooms and the interiors of public buildings that papier-mâché is found most valuable. Plaster and composition ornaments are very ponderous; carved ornaments are costly; but those of paper are light and of moderate price. In many of our theatres, in the House of Lords, in the Pantheon Bazaar, in the saloons of some of the splendid steam-boats recently built, and in numerous other instances where internal decorations are required, papier-mâché ornaments have been largely employed. Maps in relief are also occasionally made of papier-mâché.

A remarkable instance of the employment of papier-mâché is mentioned in Ersch and Gruber's 'Allgemeine Encyclopadie.' Near Bergen in Norway a church has been built capable of holding nearly a thousand persons. This building is octagonal without, but perfectly circular within. The interior of the walls, as well as the exterior of the Corinthian columns, is covered with papier-mâché. The roof, the ceiling, the statues within the church, and the basso-rilievis on the outside of the walls, are also made of this substance. The papier-mache was made water-proof, and nearly fire-proof, by an application of vitriol-water and lime slaked with whey and white of egg.

An important modification of papier mâché is that which is known by the name of *carton pierre*, or stone cardboard. This substance has been employed for half a century in France, but its use in England has been much more recent. It is a mixture of paper pulp, whiting, and glue. The mixture is pressed into moulds, then backed with paper, and removed to a drying-room to harden. The substance, when dry, is light, strong, and facile of application as an architectural ornament. It is now much used in obtaining casts of statuettes, busts, dead game, friezes, pilasters, foliage, &c. Messrs. Jackson and Graham have used this material very largely in the Army and Navy Club-house and other modern buildings.

Messrs. Bielefeld, among other inventions relating to papier-mâché, have introduced a mode of grinding fibrous and other materials into a consistence like that of putty; this is put into frames of a proper depth, rolled and compressed, heated and oiled, and finished by painting or varnishing. One among various compositions proposed is the following:—32 lbs. flour, 9 lbs. alum, and 1 lb. copper are mixed with 80 lbs. water; to these are added 15 lbs. resin, 1 lb. litharge, and 10 lbs. boiled linseed oil; the whole is finally ground up with 60 lbs. rag-dust or paper-makers' half-stuff.

PAPIST, an appellation derived from *papa*, "the pope," and which denotes a follower of the Roman Catholic church. That church calls itself catholic, which means "universal;" but as other Christian churches also style themselves "catholic," a distinction seems required to avoid confusion. The appellation Roman Catholic is generally used all over Europe to denote a follower of the church of Rome, in contradistinction to the followers of other Christian communions; but in Great Britain the words Papist and Romanist have been long in common use.

PAPYRIN. A name given to a modification of cellulose produced by immersing blotting-paper in strong sulphuric acid, then washing with water, and finally immersing for a few seconds in water containing a trace of ammonia. The paper thus acquires physical properties resembling parchment. [PARCHMENT, VEGETABLE.]

PAPYRUS. The name of a plant and the material made from it, especially that for writing used by the nations of antiquity. One of its names in the ancient Egyptian was *P-apu* (Select Papyri, Pl. xviii., l. 9.), which passed into Greek and Latin under the form *papyrus*; by the Hebrews it was called *gome*, which resembles the hieroglyphic *goma*, and Coptic *gomi*, a "book," or "volume." (Lepsius, Todt., lxxii. 162. 9.) The Greeks also called it Byblos (Herod. ii. 92.), or *deltos*, from the Delta, where it principally grew, and gave books this name (Winckelmann, ii. 96, 226, Dresd.). The term biblion, or bible, means in fact, a book or roll of papyrus. The plant itself, the paper rush, or *Cyperus antiquorum*, called *berd* by the modern Egyptians, distinguished by its tall prismatic, or triangular and tapering stem, growing to the height of about 10 feet, surmounted by a downy flower, appears to have been abundant in Egypt at the early period of the 4th dynasty. On monuments of the reign of Chephren, and Cheops, men are represented bearing bundles of this plant (Lepsius, Denkm., ii. 9-11), which they have gathered, or forming it into the light boats by which they crossed the marshes or the Nile (Lepsius, Denkm., ii. 12). The principal site of its cultivation was the alluvial ponds *uakh* (Lepsius, Denkm., ii. 74), where it is represented reaching the height of 10 feet in the Delta (Lepsius, Denkm., ii. 106 a). As early as the 5th dynasty, it appears in the hieroglyphics, either for the preparation of a colour for the eyes (Lepsius, ii. 22), or as designating the land of northern Egypt or the Delta, where it particularly grew (Ibid. ii. 47); but as the plant has gradually disappeared from Egypt, some naturalists have supposed that it was not indigenous, but introduced from the Niger or Euphrates, where it is still found native, and that it has become extinct for want of necessary culture. It has, however, been seen as late as the 19th century on the borders of the lake Menzaleh, the Phætnitic Uylarus, in Upper Egypt and in Abyssinia. Some think indeed, that the term papyrus comprehended two or three different kinds of reeds, such as the *Cyperus dives*, which is still cultivated in Egypt, and that the disappearance of the *Cyperus papyrus* is owing to the monopoly of the Roman contractors or publicani, who restricted its culture to a few localities. (Strabo, xvii. 550 c.) According to Pliny, it grew ten feet above, and two in the water, besides striking deep roots into the Nilotic mud, in the pools or marshes of the Sebynnitic and Saitic nomes.

The papyrus was one of those plants which the ancients converted to a multitude of uses. Its elegant and light flowers were woven into crowns, and neither the Spartan Agesilaus nor the Mithradates VI., of the line of Pontus, disdained to use it for that purpose, its pith or pulp was boiled and eaten, and considered the primitive food of Egypt, the root, on the contrary, was dried and used for fuel, the bark was manufactured into matting, sails, and ropes, bedding, and clothes. The priest used it only for sandals; and sandals of it remain to the present day in the collections of the British Museum. (Pliny, N. H. xiii. 11, 22; Strabo, xvii. 799. E). Boxes were also made of its stems, trimmed and tied at the ends and middle; and in an ark or box of papyrus, the youthful Moses was placed amongst the standing pools of papyri. At the time of Homer, it was used by the Greeks for rigging (Odys. xxi. 391), and Antigonus used for the cables of his fleet, papyrus grown in Syria. The ancient Greek name for the material was *bublos*, but it was not applied by prose writers to books (Lucan, iii. 222).

The invention of papyrus for boats was attributed to Isis, who searched for her husband Osiris in a bark of this material, which was said to be especially shunned by crocodiles, probably the reason why Moses was exposed in an ark of the same material by his mother. These boats are mentioned by Isaiah, Theophrastus, and Pliny. But the most remarkable use of this plant was for the manufacture of paper, *tama*, which appears in the hands of scribes on the earliest monuments (Lepsius, Denkm., ii. 6. 9. 11.) in square sheets or long scrolls, *sesht*. The process of manufacture, as described by Pliny, was to cut off both ends of the plant, the portion used was neither the outer bark nor the inner pith, but some twenty layers or pellicles under the rind surrounding the triangular stalk, those nearest the centre being the finest, which were separated by a needle. These were laid side by side upon a board, and other layers, philyræ, were placed at right angles on them, so as to cover them, and the whole cemented with Nile water, or more probably a fine glue. By continuing this process, it was possible to make the piece of any length and breadth required; and the whole was pressed, beaten with a hammer, and rubbed with tooth or shell, it was then pared, smoothed, laid in the sun, bound together and rolled out. The size and quality of this paper differs considerably, the greatest breadth being 1 foot 6 inches, or the lesser cubit; but some are not more than 4 inches, while the quality varies from a coarse and stringy to a silky material remarkably fine and smooth. The length was, of course, quite arbitrary, the longest pieces, such as the hieroglyphical ritual at Leyden, measuring 60 feet, while other portions do not exceed a few inches. The papyrus of the 18th dynasty is generally about 13 inches wide, and of a pale brownish-white colour; that of the 19th dynasty measures 9 and 11 inches, and is of a dark colour, those of the 20th are 14⅘, 11, 8, and 5 inches, and are of whiter colour and stouter texture; in the 21st, the papyrus is 8½ and 5 inches wide, and of dark colour. Some of the papyri of the subsequent dynasties are 1 foot 6 inches, or 1 foot, or 9½ inches wide, of whiter colour but coarser texture, and at the time of the 26th dynasty, the material is remarkably fine and white, but occasionally as narrow as 6 inches. The demotic contracts under the Ptolemies are written on a yellowish-brown papyrus of the average width of 11 inches, and about 20 long, while the Greek papyri, unde the Ptolemies and Romans, measure about 12½—14 inches wide; the rituals, 1 foot, 10 inches, 9½ inches, and these, as well as the Roman rituals, from 1 foot to 9½ or 4 inches, are of a stout and whiter material, not, however, so fine as those of the 26th dynasty.

The darkness of colour is probably owing to the greater age, those of the oldest period being generally the darkest and almost of a sienna colour, the material having carbonised with age, while the later are generally, but not always, white; but there can be no doubt that the contact of the rituals with the hot bitumen of the mummies has in many instances rendered the colour darker, the hieratic historical papyri, said to have been found in vases are, however, extremely dark. Papyri are found under various circumstances, but principally in connection with the mummies, as in their hands, under their arms, between their legs, or under the bandages stretched all over them like a shroud. They are generally, however, of a cylindrical form rolled upon themselves, the first page, of course, being outwards, and those of letters are sealed with a clay seal. The rituals are often placed in wooden cases, made in shape of Osiris, or Ptah Socharis Osiris, hidden in niches made for that purpose, or in the hollowed body of the deity, or else in a niche in the pedestal, so skilfully covered, joined, and painted as to elude detection by the eye. The historical and documentary papyri are said to be found in vases, boxes, and coffins.

The ink with which the Egyptians wrote on this material was an animal carbon, apparently mixed with oil; they used for the purpose a long rectangular palette or canon, from 1 ft. 8 to 9 inches long, and from 2 to 1½ feet in width, having two small cells or hollows which held a small quantity of red and black ink, the pens used were a thin, cylindrical and fibrous reed, called *kash*, the ends of which when split form a kind of natural brush. The writing is according to the nature of the document, the hieroglyphical in vertical lines of thin linear hieroglyphs, the hieratic and demotic in broader and thicker characters, generally about 10 lines to a page of 9 or 11 inches long, and in black and red characters. Compositions of the nature of books, are written with great care and regularity, official documents less so, and with characters of larger dimensions at the commencement. The religious compositions are ornamented with pictures or vignettes, traced with great delicacy, and sometimes brilliantly coloured with simple colours, and even gilded.

Considered as the books and documents of ancient Egypt, the papyri are of the greatest importance to the knowledge of the history and literature. They consist of Hermetic writings, religious and moral books, civil documents, and literary compositions in three kinds of writing, besides manuscripts in Greek of the highest literary importance. The most often repeated and extensively found, is the so-called ritual of the Dead, a copy or abridgment of which in one of the three writings was deposited with every mummy of consequence from the 18th dynasty to the Roman epoch.

This Book of Departure from the Day, and entrance into the future state, is a composition which can be traced as early as the 4th dynasty, or the pyramid builders, copies of which, more or less complete, exist in all the museums of Europe, there being probably 200 papyri relating to it in Europe. One of the copies at Leyden measures 60 feet, another in the British Museum still more; but the most complete example is the so-called ritual of Turin, written about the time of the Ptolemies, and published by Lepsius in the 'Todtenbuch.' The earliest examples are of the age of the 18th dynasty, or about B.C. 1500, with large cursive hieroglyphs written in retrograde lines; there are several of the age of the 19th dynasty, or about B.C. 1000, and one in the British Museum was made for an officer of the court of Seti I. In the subsequent dynasties the rituals are often abridged, a few of the principal chapters, chiefly those relating to the heart being given, and generally in the hieratic hand-writing which prevailed in the 26th, or Saite dynasty, which closed B.C. 525, when the hieroglyphs, if used, are smaller, but still neatly written, and the papyrus remarkably white and fine. Under the Ptolemies and Romans, mere extracts or short papyri containing excerpts of these sacred books were given; and under the Roman empire, the mummies had the allowance reduced to a single chapter. The rituals are divided into books, *shaa*, which are again subdivided into chapters, *su*, and the whole comprised in volumes, *gama*. The sheets are called *sesht*, perhaps the Roman *scheda*, the pages *sesh*, the pictures, *skher*. These vignettes, one of which accompanies each chapter, are placed above the text, and represent the principal action of the chapter, the subject of which and the commencement, as well as the directions and especial words in the text are written in red ink, and are called *skher teshr*, or "rubric." The ritual was an inspired book, and was supposed to have been dictated and written by the god Thoth himself, and the collection of which it was composed assured to the soul a transit through the purgatory and other regions of the dead, the immortality of the future life, and its union with the body, the passage to the future judgment and acquittal, protection against decay and consequent transmigration, and directions for a variety of spells of a magical nature, especially for the preservation of the heart: the most remarkable part of the doctrine is the distinct enunciation of the immortality of the soul at the remote period of B.C. 2000, everywhere spoken of as the acknowledged dogma of Egyptian theosophy.

The first sixteen chapters commence with the invocation of Thoth to Osiris, and contain various prayers, and a formula for the preparation of the sepulchral work or little figures so often found in the tomb. The 17th chapter is an esoteric interpretation of the faith—the 18th to the 21st is the Crown of Justification, in which Thoth justifies the Osiris before or against different deities, in certain mystical regions. From the 22nd to the 26th are the different spells and incantations for the preservation of the heart, tongue, and other parts of the body. The 27th to the 42nd are destined to repel the various Typhonian animals that seek to destroy the body. The 43rd to the 63rd refer to the means for escaping decapitation in Hades, corruption and pollution, and the passage in the *makhen* or mystical boat over the river of Hades. Subsequent chapters refer to the exit of the soul from earth, its expedition into Elysium and passage of the Gates of the Sun. The most remarkable of these was found in the days of king Mencheres by the prince Hartetaf, on a brick under the statue of the god Thoth in Hermopolis. The 77th to the 87th contain the transmigrations or genesis of the soul under various types in the future state. The 89th, the union of the soul and body. Subsequent chapters refer to similar ideas. From 98 to 102 is a group referring to the mystical boat, a kind of Argo, the parts of which address the deceased, and require him to tell their names before it will move. The 110th is the Egyptian *Aahlu* or Elysium, where the deceased sows, irrigates, reaps, and eats of the divine corn of the Heavenly Egypt. The 125th contains the "great judgment," the appearance of the deceased before Osiris and the 42 demons, the negative confession of the sins he has not committed, the justification by Thoth, the weighing of his heart in the balance against the feather of Truth, the devourer of the wicked, the new birth, and metempsychosis. Each part of the Hall calls out to him to tell its name before it will allow him to proceed, and the deceased then escapes the pool of fire or Phlegethon, the subject of the 126th chapter. The subsequent chapters refer to the passage of the Empyreal gateway, and the admission into the boat of the sun in which that luminary circulated through the liquid ether or Celestial Nile. Other chapters contain miscellaneous information; 137 is to restore the vital warmth; 141, 142, the knowledge of the names of the gods; 145, 146, the passage through the mystical doorways of Osiris guarded by demons, whose names the deceased has to declare. In the 152nd, the deceased enters his new mansion and drinks the waters of Nu, or life; the 154th is to preserve the soul from transmigration. Seven others give instructions for the amulets placed on the throat of the mummies; and the last, 162, for the placing of the coffin of the dead so as to be blown upon by the four winds. The ritual closes here, but at the time of the Turin ritual three supplementary chapters, 163-165, were introduced, of mythical import, referring to the worship of Amen Ra.

Besides the ritual other religious papyri are known, one the book of the Lamentations of Isis over her brother Osiris, the other the passage of the sun through the eleventh hour of the night, chiefly found with the mummies of the priestesses of Amen Ra in the age of the XX and subsequent dynasties at Thebes, and a hymn to the Nile.

The hieratic civil and literary papyri are equally interesting and important for the knowledge of the chronology and history of the country. These papyri are known under the names of their possessors, as the Prisse, Sallier, Anastasi, D'Orbiney, and Abot Papyri. Of those as yet published, the most remarkable are the Hieratic canon of the kings at Turin, unfortunately much mutilated, which originally contained a list of kings till the 19th dynasty, with the dates of their reigns, and a chronological introduction; the Prisse Papyrus, consisting of a book of moral instruction written by Ptahhetp, an officer of the 5th dynasty, and the oldest known papyrus; the I. Sallier, containing an account of transactions between the Hykshos king Apapus, and the Egyptian monarch Taakan of the 17th dynasty; the II. Sallier, the instructions of Amenemha I. of the 12th dynasty to his son Usertesen I.; and those of Sakarta to his son Papi on his return from the college at Silsilis, the IV. Sallier, an Almanac of fasts and festivals, with the religious reasons for the same, and the luck or misfortunes of each day; the D'Orbiney Papyrus, the romance of the two brothers written by Enna for the young prince Seti II. in the reign of Merienptah, a kind of novel, the plot turning on the misconduct of the wife of the eldest, the death of the younger, his revival and metamorphosis into a bull, and persea trees; the III. Sallier, or poem of Pentaur celebrating the exploits of Rameses II., against the Khita, and the grand triumph of Egypt over that people. Besides these which are literary, several documentary hieratic papyri remain, as those at Turin, dated in the reign of Thothmes III., Amenophis II., Rameses II., III., V., VI., the contents of which are as yet unpublished, and the Abot papyrus dated in the 16th year of Rameses IX., containing an account of the violation of certain royal tombs and the examination by the police. The Anastasi papyri appear to be copies of correspondence and instructions entered on the Egyptian patent rolls. In Sallier I. are ten letters of Ameneman, and one of Pentaur, about agricultural affairs, the advantages of learning, and instructions. I. Anastasi describes a journey in Palestine, III. Anastasi miscellaneous matters addressed by Amenemap to Pinebsa, giving an account of a military life. IV. Anastasi admonitions and other affairs, V. VI. VII. VIII. of the same series, letters and miscellaneous entries about judicial and other matters. A series of papyri at Leyden refer to similar matters, or magic. At Berlin a papyrus contains the receipts of an Egyptian physician.

The demotic or enchorial papyri consist principally of contracts for the sale of lands, houses, mummies, and tombs, commencing in the reign of Psammetichus I., B.C. 850, and continuing till the reign of Nero; besides which, there are in the same handwriting, memoranda, accounts, letters, translations of fragments, or later rituals by the Gnostics, Basilidians, or Valentinians, occasionally accompanied with valuable interlinear translations and words in Greek. They are chiefly important for the light they throw on the chronology of the Persians and Ptolemies, and on the changes which the language underwent at a later period. Two Phœnician papyri have also been found in a tomb of the Thebaid.

The few Coptic papyri consist principally of portions of the Old and New Testament, religious works, deeds and donations to monasteries at Gemi in the Thebaid. There are no early Arabic papyri, but this language is found in the Neskhi character, probably written in recent times on old material.

Nor are the Greek papyri found in Egypt less important; and recent discoveries have not only added considerably to the stock of Greek literature, but excited hopes of finding still greater treasures. The 150 papyri found in the vicinity of the Serapeum of Memphis have revealed the inner life and government of that temple—the mode of transacting public business, the administration of justice, the value of commodities, the state of the chancery of the Ptolemies, the rules of the religious orders, and many other curious particulars connected with the history of that temple. [SERAPEUM.] Those exhumed from the ruins of Thebes have also been of great interest, throwing considerable light upon the history of the place, especially the sale of the mummies, liturgies, and houses, the quarrels of the various classes of undertakers and others in that declining city. Besides these, letters of private individuals, advertisements for runaway slaves, a treatise on astronomy, a horoscope, and a treatise on grammar, with extracts from lost authors, and other miscellaneous writings have been found. The discovery of a book of the 'Iliad,' and of two lost orations, and portions of two others of Hypereides, have proved what important manuscripts in this material may come from the Theban tombs. The Psalms of David, in uncial characters, on papyrus, in the form of a book, have also been found in Egypt.

Although there is no doubt from the mention of papyrus, either in its natural or manufactured state, by Homer, Alcæus, Æschylus, Herodotus, and Plato, that the Greeks were acquainted with its use at an early period, yet it is doubtful if it was universally employed, notwithstanding the spurious letter of Sarpedon, said to have been written from that monarch when at Troy, and sent to Lycia. It appears from an Athenian inscription that a sheet of papyrus, *charta*, in the days of Pericles, cost 1 drachm 2 obols, or about 1*s.* 1½*d.*, which, taking the value of money at that period as four times greater than at present, amounts to about 4*s.* 6*d.* [Rhangabé 'Ant. Hell. I.,' 1842, No. 56–59; Egger, 'Rev. Contemp.' 1856, p. 171.] Probably the statement of Varro is substantially correct, and it was not much in use till the time of Alexander the Great—before which period the Greeks used palm-leaves, linen, lead, or wax. Among the Ionian Greeks *diptheræ*, or skins, appear to have been anciently employed, for they gave this name to papyri. At the time of the Ptolemies papyri and books were exported from Egypt, but the trade was stopped by the rivalry of the kings of Egypt and Pergamus—Ptolemy Epiphanes V. and Attalus, or Eumenes II., in whose reign the grammarian Crates is said to have invented *pergamena*, or parchment, or rather to have substituted its use, this material having already existed long before in Egypt—rolls of brown leather of the 14th, and of white leather or parchment of the subsequent dynasties existing in the collections of the British Museum of nearly 1000 years older than the parchments of the kings of Pergamus.

The use of papyrus in Rome dated from the earliest period, the books of Numa and the Sibyl were said to have been made of this material, but Varro, in a passage controverted by Pliny, states that the paper was first invented long after, in the days of Alexander the Great. It is clear, however, that it was in use in European and Asiatic Greece, and consequently Magna Græcia, long before. According to other authorities it was raised in Apulia and Calabria, and even in the marshes of the Tiber, in the vicinity of Rome; but there appears to be some doubt whether the Romans manufactured paper at Rome or merely improved and adapted the raw papyri exported from Egypt. In the days of the empire various kinds of papyri then in use were named from their size or fineness. The Romans prepared their paper with greater care, and sized it with a paste of fine flour stirred in boiling water with a few drops of vinegar, and some leaven, which was filtered and kept for one day; after sizing it was beaten with a hammer and sometimes sized a second time, pressed and smoothed. The names of the principal kinds were the *charta Augusta*, 12 inches broad, of a fine and white quality, anciently called the *hieratica*, because used for religious purposes, rather too thin for books, and used only for letters, hence called *epistolaris*; the *Liviana*, named after *Livia*, was the second quality; the third quality was the *amphitheatrica*, so called from being made near some amphitheatre, of 9 inches breadth, being beaten out from an Egyptian papyrus of 8 inches; an improved kind called the *Fanniana*, was prepared by the grammarian Rhemmius Fannius Palæmon, in the reign of Claudius I., 10 inches in width, and very fine, and capable of being written on both sides; the *Claudia*, invented by the same emperor, was 13 inches wide, and underlaid with a second layer; besides which there were the *emporetica*, or warehouse paper, for packing, of 6 inches; the *saitica*, made either of coarser or old material, and narrow; the *tæniotica*, very coarse, sold by weight; and other qualities and kinds as the *Thebaica*, *Carica*, *Memphitica*, named from the places where produced; the *Corneliana*, said to have been called after Cornelius Gallus; the *regia*, or royal, finer, but not large; and the *macrocollus*, larger than 13 inches. The quire, *scapus*, consisted originally of twenty sheets, or *plagulæ*, but was afterwards reduced to ten. The defects were roughness, spots, and gaps. The length of the writing on the pages was narrow, and the Herculaneum papyri do not exceed 4 inches; the writer used an ink made of soot, of pine-wood, burnt pitch, and resin, and special writers, called *chrysographi*, wrote gold letters; all wrote with the *calamus*, a Carian or Egyptian reed, on blind lines, *alokes*, generally on one side only, the back being generally stained with saffron or cedar-oil. The writings or books were rolled up upon a stick, like the Egyptian, into a cylindrical form—each cylinder was called *volumen*; and those of *Herculaneum* have the stick, *bacillus*, or the *umbilicus*, concealed in the rolls: at each end was a projecting knob, *cornu*; the edges were coloured black. Volumes were often placed in purple leather cases, called *sittybæ*; and the title of the roll, *titulus*, was written on a small strip of papyrus or parchment, *lorum*, in letters of a light red colour,—besides which, a portrait of the author was sometimes drawn on the first page of the roll. The titles of works were suspended to the door-posts, *columnæ*, of the booksellers, *librarii*, who formed an important class. Books were not very dear: a copy of the first book of Martial's 'Epigrams' sold for 5 denarii, or about 4*s.*, in the author's lifetime. The Alexandrian trade in books was very great; and nothing astonished Hadrian more on his visit to that city than the activity of the paper manufacture at Alexandria, which formed one of the staples of Egyptian commerce, which is mentioned by Philostratus, A.D. 244; and the pretender to the empire, Firmus, A.D. 272, boasted that he could feed his army off the papyrus and glue of his paper manufactory. The Alexandrian papyrus is mentioned by St. Cyril, A.D. 409, and a Latin deed of sale is known of the same century, found at Philæ. St. Jerome in this century mentions its use as universal. The use of this material continued to be universal in the following century, and there remains of this age the homilies of St. Avitus, A.D. 525; the charters of Ravenna, of A.D. 552; the homilies of St. Augustine, written on papyrus with sheets of parchment introduced; and fragments of Josephus. The most remarkable event of this age is the abolition of the paper duty by Theodoric, recorded in the pompous and flowery panegyric of Cassiodorus, A.D. 562. It is also mentioned in this century in the legend of St. Eugendus, and by Gregory of Tours, as exported from Alexandria. The Greek charters of Mauricius and Heraclius, A.D. 606–616, and the Latin of Dagobert I., A.D. 690, show its use in the east and west in the 7th century; the bull of Pope John VIII., A.D. 876, brings its use down to the 9th; and in Italy it continued to be used till the 11th or 12th, the latest known document being the bull of Paschal II. in favour of the see of Ravenna, but Eustathius, A.D. 1170, speaks of papyrus as extinct in his days; and it appears to have been quite superseded by the use of cotton-paper, *Charta Bombycina*, or *Damascena*, introduced by the Arabs from Asia, of which they obtained the knowledge in A.D. 704, according to some authorities, but no

Arabic paper manuscript bearing a date older than about A.D. 950 is known. Some indeed assert that the so-called papyri of these later centuries are really made of bark, and are a kind of charta corticea.

The most remarkable of the Roman papyri are the 1756 rolls, and fragments found in an excavation of Herculaneum, about A.D. 1753, in a book case in a small room in a house, utterly reduced to carbon, and twisted so as to resemble ram's horns, by the effects of the eruption of Vesuvius. They were at first believed to be mere billets of carbon, but letters having been observed on some, attempts were made to unrol and decipher them. The first attempts to unroll them were made by Paterni, who in 1755 incised them to the centre in two opposite places of the cylinder so as to reveal two pages, but otherwise to spoil the best papyri. The first successful attempts were made by Piaggi in 1753, and since his time no improvement on his system has been made, the attempts of Lapira, Davy, and Sickler, being equally unsuccessful. The process of Piaggi still practised at Naples, is to lay the papyrus in a convex trough on cotton supported by two uprights of wood, which lower at the pleasure of the unroller; the trough is suspended by a band passing over it at each end, and attached above: the outer portion of the papyrus is slightly saturated with gum or glue, and the layer of writing detached with a needle, and as quickly as detached fixed by the back on a layer of gold-beater's skin placed vertically; a third band passes in the middle between those of the ends, and is attached to the gold-beater's skin which is drawn up with the pages attached as the operation proceeds. After a few pages have been unrolled, the skin is cut off and the pages handed to the artists who draw and engrave them, they are then passed to the interpreters who collate and transcribe them. The process is one requiring the greatest care, experience and patience, and the progress is necessarily slow, not more than about an inch can be unrolled in four or five hours, and it took four years to unroll thirty-nine pages of Philodemus on music, and one year and a half to perform the same operation for twenty-nine pages of rhetoric. When unrolled they are framed and glazed, and published. The work proceeds but slowly, owing to the interest taken in them having diminished since their discovery, and the contents not having had the literary importance that was expected. The rolls were in the library of an epicurean, and consist of philosophical disquisitions, chiefly by the philosophers of that school; there is one treatise by Epicurus himself on Nature, another by Chrysippus on Providence, several by Philodemus on Music, Morals, and other subjects, and others by Colotes, Carniseus and Polystratus. The papyri with latin texts are differently prepared, and present still greater difficulties to unroll. Neither the dimensions nor the fabric of these correspond with the description of Pliny, and it may be generally remarked that the monuments and literature of the ancients rarely agree. The breadth of the papyri at Herculaneum is from 8½ to 12¾ inches for that of the Greek, the Latin are wider; the pages are quite black, and the letters only distinguishable in a favourable light by the greater intensity of colour, or by their polish. From the similarity of the letters it is evident the rolls were new. The space occupied by ancient libraries of these rolls appears to have been considerable; from the portion of the 'Iliad' found at Elephantine, 8 feet long and 10 inches wide, it appears that a copy of the works of Homer would require 41 such rolls. In the Alexandrian library, a separate room contained his works and those of his commentators in 1000 rolls. The libraries of the New Museum at Alexandria, and of the Serapeum have been estimated at from 54,000 to 700,000 such books or rolls. At Rome the first public library was that of Asinius Pollio, in the time of Augustus; some private individuals possessed magnificent libraries, and that of Epaphroditus, the grammarian of Chæronea, who lived from the reign of Nero to that of Nerva, had 30,000 rare books in papyri. The rooms which held these papyri were probably small, and when required for reading, a few were carried out in cylindrical boxes, *cistæ*, of bronze, standing on three legs with a vaulted cover, and placed on the floor beside the reader. The rolls stood vertical, and were taken out of the box by a strip of parchment attached. The reader fixed one end by his chin, unrolled as far as he required, and then held the roll with both hands. The first pages were called *protocolla* or protocols, the last *eskatocolla*. So important was the due supply of paper to the Roman scribes and public, that a deficiency in the reign of Tiberius gave rise to a riot.

The manufacture, for the sake of verifying the statements of Pliny, was revived in the last century. Its existence in the vicinity of Panormus at a farm called the Massa Papyreti, had been already mentioned by Gregory and by Hugo Falcandus, at a place called Papero, and in the pools of the Liane, near Syracuse, where it was discovered by the Cavalier Landolina, and a coarse stout papyrus, inferior to the ancient, produced from it, small quantities for curiosities being made to the present day. It was introduced from Egypt under the reign of one of the later tyrants of Syracuse.

The extreme value obtained by papyri, some extraordinary manuscripts having fetched from 90*l.* to 200*l.*, and all of them being a highly prized class of antiquities, menaces these ancient rolls with destruction. The Arab fellaheen, who dive into the cemeteries of Gizeh and Gournal, tear into pieces "these frail rivals of the pyramids," as they have been called, and for the sake of obtaining greater sums from the ignorance of travellers, are accustomed to make out of the unfortunate fragments fictitious rolls of papyri. They make a core or body of blank papyri, or of the dried stem of an ancient plant found in the sepulchre, and then glue over this cylindrical mass fragments of one or more broken papyri, the writing outwards in an admired confusion, tie the whole with a strip, and seal it with a clay seal bearing the impression of a scarabæus. It is painful to think how many Egyptian and Greek manuscripts of the highest value to science and literature have been in this way destroyed.

The extremely brittle condition in which Egyptian papyri are found, renders it impossible to unroll them in their actual condition without injury, but they regain their elasticity by the application of cold or hot water, or exposure to damp, and still better by carefully steaming them in a covered vessel; those that have much oil or bitumen require the application of alcohol to separate them more easily: they should then be unrolled and laid down, if only written on one side, on drawing-paper, and fixed with a paste containing alum or a slight quantity of corrosive sublimate to prevent the ravages of insects. Formerly they were unrolled on a gauze and glued at the edges, and gently pressed with linen, but it is preferable to mount them as prints. When they are only endorsed in a few places, it is merely necessary to leave the endorsements not mounted, and place over them goldbeater's skin or tracing-paper for protection. At Leyden, the papyri are fixed on tissue paper made transparent by glue, and they are rolled up; those in the Vatican are pasted on pages of cloth; those of Paris are glazed or fixed on thin but compact pasteboard; those in the British Museum are mounted in frames, or in separate pages of pasteboard and glazed. The custom of rolling up papyri is objectionable, owing to the fibres splitting with the unrolling and injuring the writing. Facsimiles of hieroglyphic hieratic, demotic, Greek, Latin, and other papyri have been published at various times, exhibiting the palæography, textures, size, and other peculiarities of these rolls.

(The principal works to be consulted are, Guilardinus, *Papyrus*, 12mo, Madrid, 1667; Mabillon, *De Re Diplomatica*, i. c. 8, p. 38 and foll.; Montfaucon, *Palæographia Græca* i. 2, p. 13 and foll.; Caylus, *sur le Papyrus*, *Mem. d'Acad.* xxvi., p. 267; Jomard, *Descr. de l'Egypte*, iii., p. 117–118; Winckelmann, ii., Bd. l.; Goodwin, C. W., *Cambridge Essays*, 1858, p. 226; *Library of Entertaining Knowledge—Egyptian Antiquities*, ii. c. 7; De Rougé, *Revue Contemporaine*, xxvii., p. 389; Chabas, *Revue Archeologique*, 1857; De Rougé, *Rev. Archeol.*, 1852; *Moniteur*, 7 et 8 *Mars*, 1851; Hincks' *Cat. of Eg. Man. Trin. Coll. Dubl.*, 8vo, 1843; Goodwin, Græco-Egyptian work on Magic, 8vo, 1852.)

PAR OF EXCHANGE. [EXCHANGE.]

PARA (coin). [MONEY.]

PARA. A prefix sometimes used in chemistry in naming compounds which either in properties or composition resemble the body to which it is attached, but differ from it in some other respects. Thus paracyanogen is a body of the same composition as cyanogen, but differs from the latter in properties. Such compounds will generally be found under the name to which the prefix is added.

PARABANIC ACID. [URIC ACID.]

PARABLE (*παραβολή*, "a comparison or similitude"), is defined by Bishop Lowth as "a continued narrative of a fictitious event, applied by way of simile to the illustration of some important truth." ('Prælect.,' x.) It is a species of fable, and differs from the apologue by narrating events which, though fictitious, are not impossible to have happened. [FABLE.] This mode of instruction is of great antiquity, especially among the eastern nations. In the Old Testament we have examples of it in the parable of Nathan to David (2 Sam., xii. 1-9), in that of the woman of Tekoah (2 Sam., xiv. 1-13), and repeatedly in the writings of the prophets (Is., v. 1-7; Ezek., xv., xvi., xix., xxxiii., &c.). The parable of Jotham, which is often spoken of as the most ancient parable in existence (Judges, ix. 7-15), is properly an apologue. In the New Testament parables form a most marked feature of our Saviour's teaching. (See the gospels of Matthew, Mark, and Luke.) Lowth lays down as the essential qualities of a parable, that the image must be well known and applicable to the subject, and its meaning clear and definite; it must be elegant and beautiful in itself; all its parts and appendages must be perspicuous and pertinent; and the literal must never be confounded with the metaphorical sense.

Many of the Scripture parables are accompanied by an explanation, which, of course, fixes the sense. Where this is not the case, the intended meaning must be gathered from a consideration of the subject-matter of the parable itself, the context in which it occurs, and the circumstances under which it was uttered.

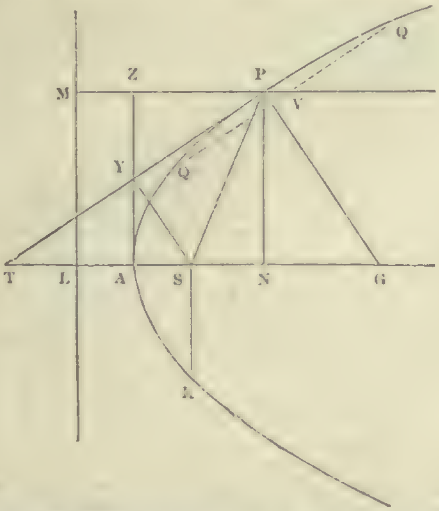
Besides its usual signification, this word is employed in the Scriptures in the following senses:—a proverb, a famous saying, a thing darkly or figuratively expressed, and a visible type or emblem.

PARA'BOLA. The probable origin of this name, as applied to one of the conic sections, may be seen in RECTANGLE. As in the case of the other CONIC SECTIONS [ELLIPSE and HYPERBOLA], we shall here give a small collection of the most remarkable properties of this curve.

1. Let a point P move in such a way that its distance S P from a fixed point S is always the same as its perpendicular distance P M from a given line M L. This point P describes what is called a *parabola*.

2. The line L S, perpendicular to L M, produced, is the *axis*, or *principal* diameter; and any line P V parallel to it is called a *diameter*.

The point S is the *focus*, and the line L M the *directrix*. The ordinate S K drawn through the focus is called the *semi-latus-rectum*, and double of it is the *latus rectum*. The same phrase is used for the ordinate drawn through the focus of an ellipse or hyperbola.



3. S A is equal to A L, and S K to twice A S.

4. If an ellipse be described with the vertex A and the focus S, the farther the centre is from the point S, the more nearly will the part of the ellipse which falls within any given ordinate P N coincide with the corresponding part of the parabola: and the same of an hyperbola drawn with the vertex A and focus S. And a parabola may be considered as an ellipse or hyperbola with a given focal distance A S, and a centre at an infinite distance.

5. The tangent P T bisects the angle M P S, and S P is equal to S T, and A N to A T. The line S Y drawn perpendicular to the tangent from the focus always meets P T in a point of the tangent drawn through A.

6. If the *normal* P G be drawn perpendicular to P T, then S P is equal to S G, and N G is always equal to twice A S.

7. The square on P N is equal to four times the rectangle under A N and A S.

8. The area A N P is two-thirds of N Z, the rectangle under A N and N P.

9. If Q Q′ be drawn parallel to P T through any point V of the diameter P V, Q Q is bisected in V, and the square on Q V is equal to four times the rectangle under S P and P V.

10. The square on S Y is equal to the rectangle under A S and S P.

In applied mathematics the parabola was formerly of great importance both as being the curve in which a comet was supposed to move, and as that in which a cannon-ball or other projectile would move were it not for the resistance of the air. It is still sometimes used as the approximation to the elongated ellipse in which a comet moves. For the more accurate investigations which deduce the real path of a projectile, see GUNNERY.

PARABOLIC REFLECTOR. It is well known in CONIC SECTIONS that lines joining the foci and any point of the curve, make equal angles with the tangent at that point; hence by the law of REFLEXION if the surface of a mirror be formed by the revolution of a conic section about its axis, a pencil of rays incident upon its surface from either focus will, after reflexion, converge to or diverge from the other focus. Mirrors in the form of a parabola are used in reflecting telescopes, and in light-houses; but in the former the incident and in the latter the reflected is the parallel pencil of rays. The conjugate mirrors used for illustrating some of the phenomena of radiant HEAT, are of this kind, and such mirrors are also being introduced for conveying fog and other signals by means of sound.

PARABOLOID. The simplest form of this surface is the paraboloid of revolution, made by the revolution of a parabola about its axis. For the other meanings of the term, see SURFACES OF THE SECOND DEGREE. The solidity of the part of the paraboloid described by the revolution of A P N [PARABOLA] is always half that of the cylinder described by A Z P N.

PARACENTRIC, or "towards the centre," a term sometimes used, as in paracentric velocity, which means the rate at which a moving body approaches a certain centre without reference to the rate at which it moves in space.

PARACHLOROBENZOIC ACID. [BENZOIC ACID.]

PARACHUTE, a French word, signifying a means of preventing a fall. The first part of the word, *para*, is perhaps of Greek origin; the second part is the French word *chute*, a fall, which is of Latin origin.

A parachute is a machine attached to a balloon, and is intended to convey the aeronaut gently to the earth, in case of an accident happening to the balloon. It is in shape like an umbrella, and its construction may be understood by supposing the umbrella to be large and strong, to be provided with ropes or stays fastened to the extremities of the whalebones, and brought down to the handle, where they must be fixed, so as to prevent the umbrella from turning inside outwards. Instead of the stick, suppose a metal tube to be fixed in the centre, with a rope passing through it, attached by its upper extremity to the balloon, and by its lower end to a tub or car. This machine is a parachute: while ascending, it will be like a closed umbrella, but it may at any moment be detached from the balloon by cutting the end of the rope which is tied to the car; the resistance of the air will then cause it to expand, and will at the same time retard the velocity of descent.

The idea of using such a machine to break the fall from a high place is not new: it has been frequently experimented with; has been found utterly useless for any desirable purpose; and has caused the death of many who have attempted to descend by its means.

Three formulas have been given for calculating the velocity of descent of a parachute. They are—

$$26\sqrt{\frac{w}{d^2}}=v$$

$$28{\cdot}28\sqrt{\frac{w}{d^2}}=v$$

$$32{\cdot}98\sqrt{\frac{w}{d^2}}=v$$

in which w is the weight in pounds avoirdupois; d, the diameter of the parachute; v the number of feet fall per second.

According to the first of these, if a parachute be 50 feet in diameter and weigh 529 lbs., it will fall 11·96 feet in a second; according to the second, the fall will be 13·01 feet; according to the third, 15·17 feet: the truth may lie between.

In these three cases, the shock felt on landing would be nearly equal to that caused by a leap from heights represented by the following three formulas respectively:—$10{\cdot}5\,\frac{w}{d^2}$; $12{\cdot}4\,\frac{w}{d^2}$; $16{\cdot}9\,\frac{w}{d^2}$; being, under the given circumstances, something less than 2 feet 3 inches, 2 feet 8 inches, and 3 feet 7 inches: a fall, therefore, of two or three thousand feet would almost certainly be fatal.

PARACHUTE LIGHT is a description of light-ball invented by Captain Boxer, R.A. It consists of two tin hemispheres, one of which is filled with light ball composition, and has a lid soldered on to it, and four fuse holes made in the convex part through which the composition burns; and the other hemisphere contains the calico parachute folded up—the calico parachute is attached by wires to the hemisphere containing the composition. The whole is placed in a paper-shell containing enough powder to burst it, and is fired from a mortar. The fuse is timed to burst it when at the greatest height. The parachute being then liberated supports the hemisphere containing the composition in the air, which burning out of the fuse-holes throws a strong light on the ground, by which an enemy's working parties and movements during the night may be discovered.

PARACYANOGEN. When cyanogen is obtained by heating bicyanide of mercury in a retort, there remains in the latter a dark-coloured substance, which was found by Professor Johnston to be similar in composition to cyanogen, that is, composed of 2 equivalents of carbon 12, and 1 equivalent of nitrogen 14 = 26. It appears therefore that it is a bicarburet of nitrogen, isomeric with cyanogen, but differing from it essentially in its physical and chemical properties, the paracyanogen being solid whilst cyanogen is gaseous. This compound is also formed when mercury is kept in an alcoholic solution of cyanogen.

PARADE is an assemblage of troops for muster, exercise, inspection, &c. The word also signifies the ground on which the exercise and drill are performed.

PARADISE (*παράδεισος*) is a word of Persian origin, signifying a kind of park or pleasure-ground inclosed with walls, and well watered and planted, and stocked with animals for the chase. (Pollux, ix. 13; Gellius, ii. 19.) It was adopted into the Greek language, and applied to any pleasant place. The Septuagint translators use this word for גַּן־עֵדֶן the *garden of Eden*, where God placed the first man upon his creation. (Gen. ii. 8; iii. 23.) Respecting the situation of this place, we are told, in Gen. ii. 8–14, that it lay eastward in the land of Eden, and that it was watered by a river, which, after passing through the garden, divided into four streams, of which the first, Pison, compassed the land of Havilah, where there was gold, bdellium (either the pearl or a sort of gum resin), and the onyx stone; the second, Gihon, compassed the land of Cush; the third was Hiddekel (the Tigris), which went towards the east of Assyria; the fourth was the Euphrates. Many attempts have been made to fix the position, but nothing satisfactory has been, or can be, ascertained, as it is clear the face of the earth, and probably the course of the streams, must have undergone great changes since the period of its existence.

PARADOS is a traverse placed in fortifications in the rear of a work, to cover it from reverse fire.

PAR'ADOX (from *παράδοξος*, "contrary to received opinion") is a term applied to a proposition which is opposed to the general belief, or to one which appears at first sight to contradict some previously ascertained truth. The nature of a paradox and the distinction between it and a contradiction is clearly explained in the following sentence from Bishop Horsley's 19th Sermon:—"When two distinct propositions are separately proved, each by its proper evidence, it is not a reason for denying either, that the human mind, upon the first hasty view, imagines a repugnance, and may perhaps find a difficulty in connecting them, even after the distinct proof of each is clearly perceived and understood. There is a wide difference between a paradox and a contradiction. Both, indeed, consist of two distinct propositions, and so far only are they alike; for of the two parts of a contradiction, the one or the other must necessarily be false: of a paradox, both are often true, and yet, when proved to be true, may continue paradoxical. This is the necessary consequence of our partial view of things. An intellect to which nothing should be paradoxical would be infinite. . . . . In all these cases there is generally in the nature of things a limit to each of the two contrasted propositions, beyond which neither can be extended without implying the falsehood of the other, and changing the paradox into a contradiction; and the whole difficulty of perceiving the connection and agreement between such propositions arises from this circumstance, that by some inattention of the mind these limits are overlooked."

This word was also used by the Greeks for a remarkable saying. Cicero, in his work entitled 'Paradoxa,' illustrates six of these paradoxes, borrowed from the Greek stoics. These propositions are the following:—1. The honourable is the only good. 2. Virtue is sufficient for happiness. 3. All sins and right actions are equal. 4. Every fool is mad. 5. The wise man alone is free, and every fool is a slave. 6. The wise man alone is rich.

PARAFFIN ($C_{20}H_{42}$?). A white crystalline body first found by Reichenbach in coal, wood, and animal tars. He found that the lower the temperature at which the tar was produced the larger the amount of paraffin formed. It is now obtained in large quantities by distilling cannel coal at the lowest temperature practicable, the rectified and purified product constitutes the basis of *paraffin oil*. The tar is filled with crystals of paraffin, which may be collected upon a strainer, and purified by pressure and treatment with concentrated sulphuric acid and caustic soda alternately.

Paraffin is a beautifully white translucent body, like spermaceti, and when manufactured into candles gives a clear smokeless light. It fuses at 110° Fahr., and is remarkable for its resistance to chemical action; hence its name from *parum affinis*.

PARAFFIN, is one of the numerous substances which chemical discovery has added to the list of liquid fuels for lamps; its nature may in some degree be shown by the proceedings in a chancery suit which took place in 1854. In 1850, Mr. Young had taken out a patent for "the treatment of certain bituminous mineral substances, and in obtaining products therefrom." It was Paraffin oil, obtained from bituminous coal. The coal was distilled at a low red heat. If a higher temperature were employed, the elements would be converted into gas and naphthaline; but the lowness of the heat prevented this, and brought over the product as an oil rich in paraffin; and this oil, when purified, became useful as a fuel and a lubricator. On the other side, it appeared that the Hydro Carbon Gas Company of Manchester were the owners of two patents, obtained by Mr. White, for inventions relating to the gas manufacture. One was for obtaining a compound gas from the vapours of oil, fat, and tar, combined with hydrogen obtained by the decomposition of water; while the other was for using resin, tar, fat, or pit coal for the same purpose, but at a white red heat. The defendants sold an oil which they called Paraffin oil, and which the plaintiff claimed as belonging to his patent. The defendant pleaded that paraffin is not a new substance, it having been produced many years ago by Reichenbach, who showed that it can be obtained from wood-tar and coal-tar. The decision was in favour of the plaintiff, as having adopted a low temperature for obtaining paraffin, on finding that a greater heat would result in the production of naphthalin.

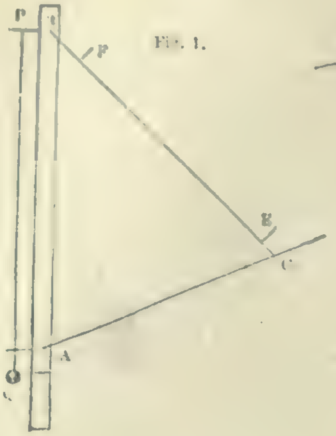
PARAFFIN OIL. [PARAFFIN.]

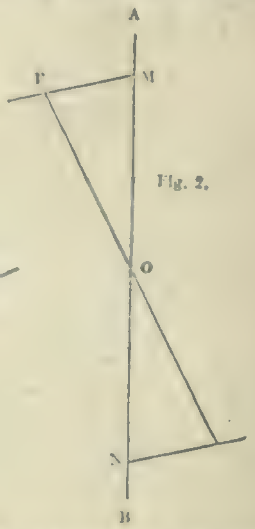
PARALLACTIC ANGLE. The angle which measures the parallax of a celestial body. [PARALLAX.]

PARALLACTIC INSTRUMENT, or *Ptolemy's Rules*, the name given to an instrument invented by Ptolemy for determining the moon's parallax, and described by him, 'Almagest,' b. v., c. 12.

A B, B C, *fig.* 1, are two stout wooden rods turning on a pin or centre at B; B A = B C; A C is a third divided rod, also turning on a pin at A, and passing through a loop or bifurcation of the rod B C at C; P Q, a plumb-line by which A B is adjusted vertically; E F, two sights fixed on C B. It is evident, if A B be truly perpendicular, and any object be seen in the direction E F, that A C will be the chord of the angle A B C, that is, of the zenith distance of the object. A C may be divided as a scale of equal parts, and the angle deduced from a table of chords, or as a line of chords to radius A B, in which case the angle may be read off at once.*

A figure of a similar instrument may be found in Tycho Brahe, 'Astron. Instaur. Mechanica,' sheet C. We have thought *Ptolemy's Rules* worth notice chiefly as pointing out a very cheap and accurate instrument for obtaining the time by the method of equal altitudes.

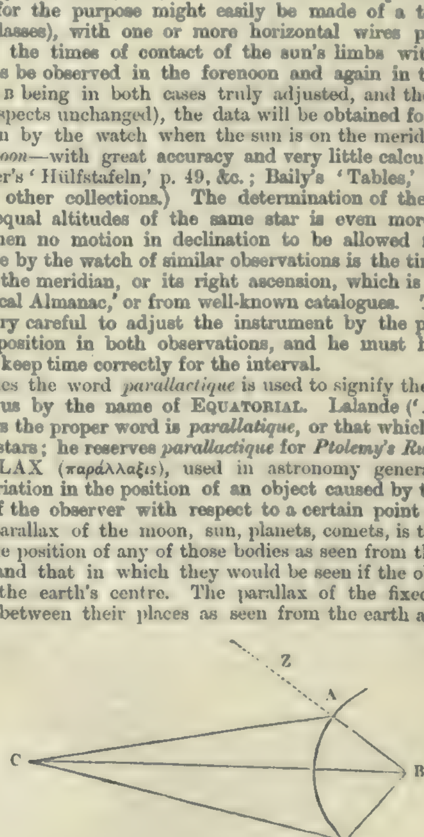




Let A B be a rod turning on pivots above and below,—for instance, between the sill and architrave of a window,—and capable of being set perpendicular by a plumb-line, supposed in the figure to hang behind A B. E C, a stout edge-bar turning round a pin at O, and fixable in any direction by two laths, E M, C N. On E C a telescope is lashed (one sufficient for the purpose might easily be made of a tin tube and spectacle-glasses), with one or more horizontal wires placed in the focus. If the times of contact of the sun's limbs with the horizontal wires be observed in the forenoon and again in the afternoon (the axis A B being in both cases truly adjusted, and the instrument in other respects unchanged), the data will be obtained for finding the time shown by the watch when the sun is on the meridian—that is, *apparent noon*—with great accuracy and very little calculation. (See Schumacher's 'Hülfstafeln,' p. 49, &c.; Baily's 'Tables,' pp. 92, 148, and many other collections.) The determination of the error of the watch by equal altitudes of the same star is even more simple, as there is then no motion in declination to be allowed for, and the middle time by the watch of similar observations is the time when the star passes the meridian, or its right ascension, which is known from the 'Nautical Almanac,' or from well-known catalogues. The observer must be very careful to adjust the instrument by the plumb-line to the same position in both observations, and he must have a watch which will keep time correctly for the interval.

Sometimes the word *parallactique* is used to signify the instrument known to us by the name of EQUATORIAL. Lalande ('Astronomie,' § 2278) says the proper word is *parallatique*, or that which follows the *parallel* of stars; he reserves *parallactique* for *Ptolemy's Rules*.

PARALLAX (παράλλαξις), used in astronomy generally for the angular variation in the position of an object caused by the excentric situation of the observer with respect to a certain point of reference. Thus the parallax of the moon, sun, planets, comets, is the difference between the position of any of those bodies as seen from the surface of the earth and that in which they would be seen if the observer were placed at the earth's centre. The parallax of the fixed stars is the difference between their places as seen from the earth and from the sun, which is for these observations the point of reference. All bodies within the solar system are in the first instance referred to the earth's centre; while those beyond our system, as the fixed stars, are referred



---

* Some liberties have been taken with Ptolemy's description, and several omissions made. He seems to have been singularly unlucky as an observer, for at 50° 55′ Appar. Zen. Dist. he found the moon's parallax = 1° 7′, whence the horizontal parallax is 1° 26′, and the distance of moon from the earth 39·8 of the earth's radii. He has drawn the latter conclusion, but fortunately seems not to have used it in his theory.

to the centre of the sun, and the change arising from excentric position in each case is called parallax.

From the effects of parallax we derive all our knowledge of the distance and magnitude of the bodies which are visible in the heavens.

Let A B be any line the length of which is accurately measured, and let the angles C A B, C B A, be observed, then the distances C A and C B can be computed. In this way trigonometrical surveys are made, with the further precaution that the angle A C B is observed when this is possible, and C is to be fixed with great nicety. The angle A C B is known, since it = 180° − (B A C + A B C), and we have A B : B C : : sin A C B : sin C A B. In the above figure, let A be the position of a spectator on the earth's surface, B the centre of the earth, C the moon, and Z (in B A produced) the geocentric zenith. Then Z A C is the apparent geocentric zenith distance at A; Z B C the true geocentric zenith distance, that is, that which would be seen from the centre of the earth; and A C B = Z A C − Z B C, the moon's parallax: also

$$\sin \text{parallax} = \frac{AB}{BC} \times \sin \text{Appt. geocent. zen. dist.}$$

When A C is at right angles to B A, this sine = 1, and the moon is in the horizon. This value of the parallax is called the *horizontal* parallax; naming this P, and any other value of the parallax p, we have

$$\sin P = \frac{AB}{BC}, \text{ and}$$

$$\sin p = \sin P \times \sin \text{appt. geocent. zen. dist.}$$

It is evident that if P can be measured, the distance R of the moon's centre from the centre of the earth can be found, for the other quantity A B or r is the radius of the earth at the place of observation, which is known from terrestrial measurement. Now, suppose a second spectator on the same meridian at A′, whose geocentric zenith is Z′, and that the two observers each observe the moon upon the meridian at the same moment: then, if z and z' be two observed geocentric zenith distances, and p and p' the parallaxes, $P = \frac{BA}{BC} = \frac{r}{R}$, $P' = \frac{BA'}{BC} = \frac{r'}{R}$, and

$$\angle ABC = z - p$$
$$\angle A'BC = z' - p',$$

and adding $ABA' = z + z' - (p + p')$, where A B A′ is the sum or difference of the geocentric latitudes of A and A′, and z and z', are known by observation; hence the value of $p + p'$, or A C A is found. From the equations

$$p + p' = z + z' - ABA'; \ \sin p = \frac{r}{R} \sin z; \ \sin p' = \frac{r'}{R} \sin z';$$

it is easy to find the value of R.

In practice, though the process is less simple, the principle remains the same. Two distant observatories can scarcely be found exactly on the same meridian; but the tables of the moon enable us to reduce the observation at one of the observatories to exactly *what it would have been* if it had been made under the meridian of the other. When the parallax is small, it is advisable to compare the planet by the *micrometer* with stars which are nearly in its parallel. When the parallax, and consequently the distance, for any given time is known, the distance and parallax for any other time can be found from theory. By observations of this kind, combining the observations of La Caille at the Cape of Good Hope with other observations made in Europe, the parallax of the moon and of Mars were fixed with great accuracy. The late Professor Henderson investigated the value of the moon's parallax from a comparison of his own observations at the Cape with those made at Greenwich and Cambridge. ('Mem. Ast. Soc.,' vol. x., p. 283.)

It will be seen that the point from which the moon's zenith distances are to be measured is in the prolongation of a line drawn from the centre of the earth, and not in the prolongation of a line in the direction of gravity, which is pointed out by a plumb-line. The correction which is to be applied to the astronomical zenith, in order to find out the geocentric zenith, is given in many collections of tables for a certain hypothesis of the figure of the earth. The horizontal parallax given in the 'Nautical Almanac' is that which belongs to the equator where the earth's radius is largest. A second table for reducing this equatorial horizontal parallax to the parallax proper to the place of observation (namely, log. rad., supposing the equatorial rad. = 1) always accompanies that above referred to.

Parallax of the Sun.—The first attempt to determine the sun's distance seems to be due to Aristarchus of Samos, and presupposes the knowledge of the moon's parallax. On drawing a figure, it will immediately be seen that when the moon has completed her first quarter (she is then said to be *dichotomized*, or cut exactly in two), the sun, moon, and spectator form a triangle, which is right-angled at the moon. Now the angle which separates the sun from the moon can be observed at the same instant: suppose it = E, we have

Distance earth & sun = distance earth & moon × sec. E.

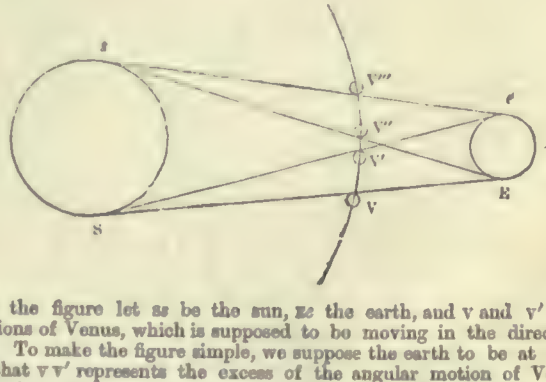
The exact moment of *dichotomy* cannot be noted with much accuracy; yet repeated observations would show that the sun was far more distant than the moon. The ancient astronomers seem to have estimated the sun's parallax to be from 2′ to 3′, which suffered a gradual reduction as the means of observation improved. The parallax of the sun might with modern instruments be measured in the same way as that of the moon or planets above described, but not so well, as a longer time must elapse between the passage of the sun and that of a star nearly in the same parallel. Ptolemy says that Hipparchus computed the moon's parallax from the phenomena of solar eclipses; that is, he deduced the value of the moon's parallax from the phenomena of solar eclipses on two suppositions of the sun's parallax: namely, that it was = 0; and, again, that it was a definite small quantity. As the circumstances of a solar eclipse vary from the effects of parallax, it is clear that in this way Hipparchus would get something like equations of condition involving the parallaxes of the sun and of the moon, which could be solved as soon as, by the problem of Aristarchus or by any other method, he could determine the relation between these two quantities.

We have thus shown that an approximate knowledge of the distances of the moon, sun, and planets, in terms of the magnitude of the earth, requires nothing more than observation and the solution of a triangle one side of which and the two including angles are known. The magnitudes of these bodies can be immediately calculated from their apparent diameters and true distance; so that up to this point there is no room for scepticism, if it be granted that the angles of a triangle equal two right angles.

There is a method of ascertaining the parallax by one observer. Let Mars in opposition be the object, and compare it in right ascension with a neighbouring star in the same parallel on the meridian, and also several hours before and again after his transit. The parallax, being wholly in a vertical circle, will not affect the right ascension in the meridian: hence the meridian comparison will give the true difference of right ascension between the planet and star. The other observations (after correcting the place of Mars by his hourly motion, which is known either from the tables or from observations on preceding and succeeding days) present right ascensions of the planet affected by parallax in different ways, and from these effects it is easy to compute the actual value of the horizontal parallax, and consequently the distance of the planet in terms of the earth's radius at the place. This method has recently been proposed by the Astronomer-Royal, as well adapted for determining the parallax of the star from observations made during the oppositions of 1862 and 1864.

Kepler's discoveries *—that the planets move in ellipses round the sun in the focus; that the area swept by each radius vector in a given time is a constant quantity for the same planet; and lastly, that the squares of the periodic times are as the cubes of the mean distance—have supplied means for a much more accurate determination of the sun's parallax. Assuming these laws, the *forms* of the orbits of the earth and planets, and their *relative* distances, can be determined from observation: hence, if the parallax of any one planet can be found, the parallaxes of the sun and of all the other planets can be computed. Observations of Mars, for instance, at his opposition, made at the Cape of Good Hope and at Greenwich, will afford a very tolerable value of his parallax, and hence of his distance. Again, as the proportion between the distances of Mars and the earth from the sun at any time is known from the form of their orbits and their periodic times, and the angle between the sun and Mars at the earth can be observed, the triangle between the sun, earth, and Mars can be completely solved, and hence the distance of the sun and his parallax be computed. These observations can be repeated at every opposition of Mars; and if Mars be compared by the micrometer with stars near the same parallel, there is scarcely a limit to the possible accuracy of the observations.

The observation however by which the parallax of the sun is determined with the greatest certainty, is that of the passage of Venus over the sun's disc, commonly called the *transit* of Venus. [TRANSIT OF VENUS.]



In the figure let Ss be the sun, Ee the earth, and V and V′ two positions of Venus, which is supposed to be moving in the direction V V′. To make the figure simple, we suppose the earth to be at rest, and that V V′ represents the excess of the angular motion of Venus above that of the earth. A spectator at E will see the commencement of the transit when Venus is at V, but a spectator at e will only begin to see it when Venus is at V′. The time which must elapse between these two moments is equal to the time in which Venus passes from V to V′, or in which she describes the angle ESe round the sun with her *relative* angular motion. But the angle ESe is twice the sun's horizontal parallax; hence, since the time elapsed between the ingress at the two places is known from observation and from the difference of longitudes, and the hourly angular motions of Venus and the earth round the sun are known from the tables, and consequently the difference of these motions, the horizontal parallax of the sun can be found. It is evident that as the ingress is accelerated at E and retarded at *e*, so the egress will be accelerated at E and retarded at *e*, Venus then occupying the positions V″, V‴.

---

* Though these discoveries are due to Kepler, the satisfactory proof of their truth was given by Newton.

Let us suppose further that a spectator who saw the ingress at E, and therefore as early as possible, should by the rotation of the earth be carried to *e*, where he would see the egress as late as possible, while the spectator of the late ingress at *e* is in like manner carried to E, where he sees the earliest egress.* In the first case the time of the transit is increased as much as possible by the effect of parallax, and in the latter case it is equally diminished. Now suppose the parallax of the sun to have a certain value, the parallax of Venus and the effect of these parallaxes in increasing or diminishing the duration of the transit for any specified places of observation can be computed. Hence when the durations are really observed, the differences between the observed duration and that which would have been observed if the spectator had been placed at the centre of the earth will fix the actual amount of the parallax. The especial excellence of this method consists in the nicety† with which a particular phenomenon can be observed, namely, the first streak of light which is seen after the interior contact at ingress and the last streak before the interior contact at egress. Two points on the earth are chosen where the beginning and end are both visible, in one of which the duration is shortened as much as possible, while it is increased in the other. Every observation of either ingress or egress can in fact be used for determining the parallax, provided the longitude of the place of observation and the time be sufficiently well known; but where both the ingress and egress are observed, the duration alone requires care. Transits of Venus were observed in 1761 and 1769, and the parallax of the sun deduced by various geometers. (Lagrange, 'Mémoires de Berlin,' 1766; Encke, 'Der Venus Durchgang,' Gotha, 1824.) The next transits will take place in 1874 and 1882.

In the preceding part of this article the methods of determining the parallaxes, and consequently the distances of the bodies composing our system, have been described, and we will now point out the way in which this knowledge is applied. Every observation of the sun, moon, or planets is affected by parallax and must be corrected for this previous to further calculation. All celestial bodies are apparently elevated by the refraction of the atmosphere, and those of our system are depressed by the effect of parallax. In nautical works there are tables for reducing the observed altitude of any heavenly body to its true altitude, namely, to that which it would have if there were no atmosphere and the spectator were at the earth's centre. In most of the problems from which the longitude is determined astronomically, in solar eclipses, occultations, and lunar distances the great difficulty and trouble is in computing the effect produced by the moon's parallax. Astronomers have invented convenient formulæ for this purpose, according to the planes to which the bodies are referred. Thus in working out an occultation, the moon may be referred to the plane of the *horizon*, when the effects of parallax in altitude, and, if great accuracy be required, in azimuth, must be computed; or again, to the *equinoctial*, when the parallax in right ascension and declination is to be calculated; or finally, to the *ecliptic*, when the parallaxes in longitude and latitude must be found. The rules for these computations are given in treatises on Astronomy.

The mean equatorial horizontal parallax of the sun, according to Encke, = 8·5776″. Its true value for every ten days is given in the 'Naut. Alman.' at the end of the ephemeris of the sun and moon. The equatorial horizontal parallax of the moon for mean noon and midnight is at page III. of each month, and the parallaxes of the planets are in the last column of the planetary meridian ephemeris.

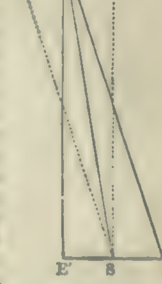
One effect of parallax is, that the moon appears under a larger angle when near the zenith than when near the horizon. This is contrary to common opinion, but may be very easily proved experimentally, by any one who can handle a sextant with ordinary care. When the moon is in the zenith, the horizontal diameter may be *augmented* from 30″ to 40″. There is a table for this augmentation of the moon's semidiameter in most nautical works.

Constant of Parallax (*la constante de la parallaxe*) is the angle under which the earth's radius would be seen at the centre of the moon when she is at her mean distance. The radius chosen by La Place is that which belongs to a latitude of which the square of the sine = ⅓.

PARALLAX, ANNUAL, is the angle under which the earth's orbit is seen by a superior planet.

PARALLAX OF THE FIXED STARS. When Copernicus proposed his hypothesis of the earth's motion, one striking *astronomical* objection was, that the enormous displacement of the spectator's place which his system supposed was not supported by a corresponding change in the positions of the fixed stars. Every improvement in instruments, in the art of observing, or in the science of computation, seemed to increase the distance of the sun, and consequently the orbit of the earth, and still no sidereal change could be detected. Hence, until the discoveries of Newton brought forward physical arguments, of which, however, the conclusiveness is not immediately visible, the Copernican hypothesis was embraced on the grounds of its symmetry and simplicity rather than on demonstration. Opponents might always ask for the *experimentum crucis*, the effects of the earth's motion in the apparent displacement of the fixed stars, and this could not be supplied.

Many attempts were, however, made. Hooke erected a zenith sector at his chambers in Gresham College, and made some incomplete observations in which he fancied he could trace the effects of parallax. Flamsteed found variations in the north polar distances of fixed stars, which he attributed to parallax, although, as was shown by Cassini and Roemer, this would have produced results with a totally different law. Roemer himself, after many efforts to deduce parallax from observations in declination, renounced the attempt, on account, as he says, of "a certain variation in the declinations of stars which can neither be attributed to refractions nor parallaxes," and pursued his investigation by observations in right ascension, in which it seems he believed himself to be successful. At length Bradley commenced the research with far better astronomical means, and by his discoveries of aberration and nutation, fully explained the phenomena which had perplexed his predecessors. It is curious that Roemer, who had discovered the gradual transmission and finite velocity of light, should have been perplexed with the necessary results of this very property in another shape; and that Bradley, while pursuing the problem of parallax, which had been originally interesting as a proof of the earth's *change of place*, should have hit upon phenomena which satisfactorily proved the earth's *motion*, and so confirmed the Copernican hypothesis by evidence different from what he sought. Bradley's observations further showed that the effect of parallax in any of the stars observed by him could not amount to 2″ and probably was not 1″.



The nature of the changes in the places in the fixed stars, which the change of position in the earth would produce, may be seen from the following figure. Let S be the place of the sun, E that of the earth, and *s* that of a fixed star. Then the star is seen from the earth in the direction E *s*, and from the sun in the direction S *s*; the difference in these two directions is the angle E *s* S, that is, the angle of parallax. If S *s*′, *s s*′, be drawn parallel to E *s*, E S, and the observations made from the earth be referred, as observations of this kind are always supposed to be, to the sun, the true place of the star is at *s*, while the place which is assigned to it by observation is *s*′. At the end of half a year the place of the earth will be at E′, and the star is seen in the direction E′*s*. Hence it is referred to the position *s*″ in respect of S. It is evident that the effect of parallax is to cause the star to appear to describe an orbit round its true place in a plane parallel to the ecliptic, similar and equal to the earth's orbit round the sun; and further, that parallax is always in a plane passing through the star, sun, and earth, and that its effect is to diminish the angle which the sun and star subtend at the earth. When this is clearly conceived, it will also be seen that this ellipse, which is similar to the earth's orbit, will be seen obliquely from the earth, and consequently be projected into another ellipse with altered proportions. The same figure would serve for an explanation of aberration, except that aberration is in a plane defined by the star and the *direction* of the earth's motion, which direction is at right angles to the line joining the earth and sun, so that the *phenomena* of parallax and aberration are similar, only the effect of parallax is at right angles to the effect of aberration. This affords a convenient mode of computing the coefficient of parallax when that of aberration is known.*

There is another view of parallax. Suppose a spectator at the star *s*; then he would see the earth's radius vector S E under the angle of parallax. The earth's orbit may be considered to be circular, and as the plane is inclined to a spectator anywhere except in the pole of the ecliptic, the earth will appear to describe an ellipse about S as

---

[*] The explanation is only intended to exhibit the *principle* on which this very important problem depends.

[†] This observation seems not to have been quite as definite as was expected; a little confusion was remarked at the point of interior contact before the formation of the thread of light, a sort of black drop (gutta nigra). Mr. Baily saw several black threads connecting the edges of the sun and moon during the formation and breaking up of the annulus in the eclipse of May 15, 1836 ('Mem. Ast. Soc.,' vol. x. p. 1), which seems to be a phenomenon of the same kind.

[*] This similarity between aberration and parallax is not rigorous, but nearly so. It would be strictly true if the earth moved uniformly in a circle. There are convenient tables for computing aberration for a given constant of aberration. Calculate the aberration by these tables for ⊙ + 90°, ⊙ being the sun's longitude at the time, divide by the seconds of the constant of aberration, and you have the coefficient of parallax, the parallax being supposed = 1″. Also the times when the parallax in right ascension or declination is the greatest possible will be when the effect of aberration in those directions is 0, and *vice versâ*.

centre. The nearer the star *s* is to the ecliptic, the more excentric this ellipse will be,[*] but in all cases there is a diameter of the earth's orbit, namely, that which is perpendicular to the line joining S *s*, which is seen in its true proportions without foreshortening.

Since Roemer and Bradley, many astronomers have sought for parallax by observation in right ascension and declination. Bessel could find no evidence of such an effect in Bradley's transit or zenith distance observations. Piazzi, from meridian zenith observations, concluded that Sirius had a parallax of 4″ and Procyon one of 5″·7; Calandrelli found a parallax of 4″·4 in α Lyræ. But the most persevering and accurate observations for deducing the value of parallax from meridian observations were prosecuted by Dr. Brinkley at Dublin with an 8-foot circle by Ramsden, and by Pond at Greenwich with the 6-foot mural-circle of Troughton. Dr. Brinkley conceived that he had established without doubt a sensible parallax in α Lyræ, α Cygni, and α Aquilæ, while Pond maintained that no sensible parallax was shown in any of those stars, from observations in declination and in right ascension. He further corroborated this result by comparing two stars, α Cygni and β Aurigæ, which have nearly the same declination and opposite right ascension, with a fixed tube. This controversy continued for several years, and though there can be no doubt *now* that Dr. Brinkley was mistaken, and that Pond was right in his conclusions, there is a good deal of interest attached to the discussion. Dr. Brinkley's last memoir is in the 'Transactions of the Royal Irish Academy,' vol. xiv. Mr. Pond's paper on the parallax of α Lyræ will be found in the 'Phil. Trans.,' 1823, part i., p. 53.

Sir William Herschel first pointed out the mode of detecting parallax which affords a probability of success, namely, that which depends upon the measurement of double stars. In his paper, 'Phil. Trans.,' 1782, part i. p. 82, he showed that if the stars which compose a double star be at different distances from the earth, which was at that time supposed to be the chief cause of differences in magnitude, they must be differently affected by parallax, and therefore that their apparent distance from each other will be altered by a change of position in the spectator. Now as the apparent distance of two neighbouring stars can be measured with great accuracy,[†] the problem of parallax is thus reduced to that of finding a double star in which a variation of distance is observable, and following the law which the earth's change of place requires. It was in this inquiry that Sir William Herschel discovered that very many double stars have a relative motion both in distance and angular position, which proves them to be a connected system, and that unexpected result, which he prosecuted with all his ardour and genius, seems to have led him from the investigation of parallax into his profound and original researches. Sir John Herschel ('Phil. Trans.,' 1826, part iii., p. 266,) extended his father's proposal for the discovery of parallax by showing that the variation produced by parallax in the angle of position of two stars is a more sensible phenomenon and one more easily measured than the variation in distance; and in the 'Phil. Trans.,' 1827, p. 126, he published a considerable list of stars suitable for his research, with the times of year when the observations would show the greatest effect of parallax.

It has been shown that the earth's change of place in its orbit causes each star to have an apparent motion in an ellipse of which the major axis is parallel to the ecliptic and equal to the diameter of the earth's orbit as seen at the distance of the star, and the minor axis equal to the major × sine *'s latitude. If then the stars be a connected system, and comparatively near each other, the stars will appear to describe two equal and similar elllipses, and the line joining their apparent places will be equal and parallel to the line joining their true positions. It is therefore in vain to look for any effect of parallax in micrometrical or relative measures of distance and position in a connected system. But if one of the stars be much farther from us than the other, suppose it ten times farther off, then the apparent ellipses will continue to be similar, and similarly described, only the dimensions of that described by the more distant star will be 1-10th of that described by the nearer star, which comes to the same thing as supposing the more distant star to be fixed, and the nearer star to describe round its true place an ellipse of 9-10ths the actual dimensions. If with Sir William Herschel we measure the apparent *distances* of the two stars, those are best suited to the purpose in which the line joining the stars is in the direction of the major axis of the parallactic ellipse, that is, is parallel to the ecliptic. If we proceed by measures of position, as recommended by Sir John Herschel, those stars are most favourable in which the line joining the two stars is perpendicular to the ecliptic. It is scarcely necessary to say that these conditions are not rigorous, and that stars tolerably near the pole of the ecliptic are equally well suited to either kind of measure, as the apparent ellipse is then almost a circle. Since the application of clock-work to large equatorials, we think that the measures of the distance of double stars may be made nearly as accurately, and even more easily, than angles of position; and further, that any telescopes which have yet been constructed may be mounted equatorially and carried by clock-work. Most of the close double stars are probably connected, and are therefore unfit for the detection of parallax.

In the last-named property, that of measuring considerable angles, the heliometer is unrivalled, and thus we see its especial use in the researches connected with parallax. It is almost hopeless to attack the problem by any other means at present known; and the divided eyepiece, which is found very useful for *small* measures of distance, is, like the wire micrometer, *limited* to this object.

For his researches on parallax, Bessel selected the double star 61 Cygni, which is a double star having a large proper motion. This property leads us naturally to guess that it is a comparatively near star, as its actual velocity would otherwise be enormously large. Two stars *a* and *b* were chosen, *b* in the direction joining the component stars of 61 Cygni, and *a* at right angles to this direction. The observations of *b* are made by bringing it into the middle of the two stars, those of *a* by placing it in the same line with the two stars. As the two stars of 61 Cygni are nearly of the same brightness, the observation is exceedingly accurate. These measurements were continued for fourteen months with very little interruption. The stars *a* and *b* are so far removed from 61 Cygni as to render any connection highly improbable. Variations were found in these distances, which, being compared with the effect which parallax would produce, are *exactly* accounted for; therefore this variation is produced by parallax, for it can be shown that any other *known* cause of disturbance has been got rid of by the skill of the observer. The result is that the parallax of 61 Cygni is 0″·314; whence the distance of 61 Cygni is 658,000 times the distance of the earth from the sun, and light from the star is 10¼ years in reaching us.

This result has received a most satisfactory confirmation from the researches of Professor Peters, and those of the late Mr. Johnson, director of the Radcliffe Observatory, Oxford. The value deduced by the former of these astronomers, namely, 0″·349, was founded on observations made by himself with a vertical circle at the Imperial Observatory of Pulkowa. In 1852-3 Mr. Johnson measured the distance of the star from two other small stars in its vicinity with the Oxford heliometer, and obtained 0″·384 for the value of its parallax.

The parallax of α Lyræ, was determined by M. Struve, in the year 1835. The method employed by him consisted in measuring with a wire micrometer the distance of the star from another bright star in its vicinity. In this way he found the parallax of α Lyræ to be 0″·261. The parallax of this star has also been investigated by Professor Peters, M. Otto Struve, and Mr. Johnson. M. Otto Struve, by combining his own value of the parallax of the star with the values obtained by his father and Professor Peters, obtained 0″·1549 for the definitive result. Mr. Johnson obtained very imperfect evidence in favour of a sensible parallax of the star.

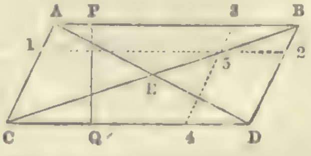
The late Professor Henderson, of Edinburgh, determined the parallax of the bright star α Centauri, from observations made by himself with the mural circle at the Cape of Good Hope in the years 1832-3. In this case, the resulting parallax was large, amounting to 1″·16. Mr. Maclear, from observations made at the Cape in the years 1839-40, found the parallax of the same star to be 0″·9128; and from subsequent observations extending down to 1848, he deduced 0″·9187 as the most probable value of the parallax. The parallaxes of several other stars have been investigated in recent times, but no trustworthy results have yet been arrived at.

PARALLAX, in practical optics, is the longitudinal misplacement of the wires in a telescope or microscope. If the wires are not at a proper distance from the object-glass, the image of the object is not seen distinctly when the wires are so seen. On giving a little motion to the eye, the object will seem to move upon the wires. If it move in the direction of the eye, the cell carrying the wires must be pushed in, and *vice versâ*. There are means for this adjustment in all instruments which require it, and it is a point to which the attention of observers should be very carefully directed.

PARALLEL. [PARALLELS.]

PARALLEL PRESSURES. [PRESSURE.]

PARALLELOGRAM (παραλληλό-γραμμα, parallel-drawn figure) is the mathematical term for a four-sided figure of which the opposite sides are parallel. Such a figure may be obtained from *any* four-sided figure by bisecting the four sides and joining the adjacent bisecting points. When all the angles of a parallelogram are equal, they are therefore right angles, and the figure is called a RECTANGLE. When the sides are also equal, the figure is a SQUARE: matters of more historical interest are connected with either of these terms than with the generic term parallelogram. Referring therefore to those articles, we shall here give the principal properties of parallelograms in general.



1. The opposite sides are equal, as AC and BD.
2. The opposite angles are equal, as ACD and ABD, and adjacen

---

[*] The semi-axis major is the earth's radius vector, and the semi-axis minor is the earth's radius vector × sin of *'s latitude.

[†] It is perhaps more easy to determine the distance of a double star to 0″·1 than to fix an absolute place to 1″·0.

angles (as those at A and B) are together equal to two right angles, or are *supplements* of each other.

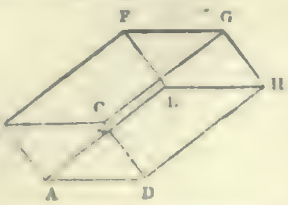
3. The diagonals (A D and B C) bisect one another.

4. The sum of the squares on the four sides is equal to the sum of the squares on the diagonals.

5. The area of a parallelogram depends only on the side (as C D) and the perpendicular distance (P Q) between that and the opposite side; so that parallelograms on equal bases and between the same parallels are equal.

6. If the point (5) be taken on a diagonal (C B) and made the vertex of a pair of parallelograms (A 153 and D 452) lying in the equal triangular halves of the parallelogram, these parallelograms will be equal to one another in area.

PARALLELOPIPED (παραλληλ-επίπεδον, parallel-plane solid) more correctly written *parallelepiped*, is the name given to a solid contained by six parallelograms, which are equal and parallel, two and two. It is in fact a quadrangular prism.



When all the parallelograms are rectangles, we have one of the figures to which our eyes are most accustomed, as in the case of a die, a box, a plank, a room, &c. &c. Persons not acquainted with mathematics would hardly believe that English mathematicians seldom express this most simple and elementary of all solids in less than ten syllables, as follows:—

rect-an-gul-ar par-all-el-o-pi-ped.

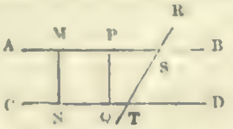
A more simple term might easily be obtained, and one perfectly consistent with analogy, namely *right solid*. Thus a right line might be conceived as generated by the most simple motion of a point; a right surface (or rectangle) by the most simple motion of a right line; and a right solid (or rectangular parallelopiped) by the most simple motion of a right surface. We shall consider the properties of a right solid in the article RECTANGLE.

When the adjacent rectangles of a right solid are squares, the solid is a CUBE, for which fortunately there is a shorter term than equilateral rectangular parallelopiped.

The number of cubic units in a parallelopiped is found by multiplying the number of square units in either base by the number of linear units in the perpendicular distance between that base and the opposite one. The diagonals A G, B H, C E, D F, meet in the same point, which bisects them all, and the sum of their squares is equal to the sum of the squares of all the twelve sides of the solid.

PARALLELS (παράλληλα, by the side of each other), the name given by the Greek geometers to lines in the same plane having that relation of situation of which it is one of the most obvious properties that such lines never meet, however far they may be produced or lengthened.

If we examine the properties of lines experimentally, it will be easy to satisfy ourselves of the existence of such pairs as A B, C D, which neither diverge nor converge, and to which common perpendiculars, such as M N and P Q, all of the same length, can be drawn through any point of either. Moreover the angles R S B and R T D made by the same line with both, will be found to be the same. If then we take the notion of permanence of direction which always accompanies that of straightness [DIRECTION], and also the notion of differing directions, which is suggested by two lines which make an angle, we may readily see that the relation of situation which, adopting Euclid's term, may be called *parallelism*, is really that which would be also conveyed by the words sameness of direction; so that if two lines A and B be parallel, A may be substituted for B or B for A, in any proposition which involves relations of direction only, without affecting the truth of that proposition if true, or its falsehood, if false.



Geometry, as every beginner knows, depends upon a small number of self-evident truths, or rather of propositions the truth of which (*with one exception*) is so soon and so easily perceived, that no one doubts of them when stated with ordinary attention to clearness of expression. The exception alluded to appears for the first time in Euclid, and has been the occasion of a controversy which has lasted from his time to the present.

It will be remarked that the definition of parallel lines is purely negative: it describes what they are not, not what they are: if lines which meet, or which will meet if produced, be called intersectors, parallels are non-intersectors. Those who would found geometry upon definitions entirely, may think that the difficulty of the theory of parallels arises from insufficient definition: but those who believe it to be deducible from real and positive conceptions, having nothing arbitary about them, must suspect that, in this purely negative definition of parallels, we have not sufficiently described that very obvious relation of position which distinguishes parallelism from convergence, however short the lines we image to ourselves, or however little we think of what will take place if they are produced. Euclid, proceeding upon axioms the admission of which is not considered to be a question connected with the present difficulty, establishes the following proposition:—If the two lines S B and T D make the angles P S T and S T D equal, or R S B and S T D equal, or B S T and S T D together equal to two right angles (all which amount to the same thing), then S B and T D are non-intersectors. But before any further step can be made, it must either be proved or assumed that in every other case they *are* intersectors, and Euclid, being unable to prove it, assumes it directly. That is to say, he requires it to be granted that if B S T and S T D be together less than two right angles, S B and T D will meet, if produced, and on that side on which they make with S T the angles less than two right angles. The last clause is not a necessary part of the axiom, since it can be shown, independently of the present theory, that two lines which meet must make angles together less than two right angles with any line which cuts them internally on the side of meeting.

Euclid obviously puts the *whole* difficulty into an assumption; which, though the most direct course, is not that which is best calculated to give the highest degree of evidence to geometrical truths. For it is a more obvious proposition that two lines which intersect one another cannot *both* be parallel to a third line, and this being granted, Euclid's axiom readily follows. If it should be objected that this is merely Euclid's axiom in another form, it is replied that the form is a more easy one, and therefore preferable: just as it would be wiser to assume "Every A is B and every B is A," than the identical but more complicated proposition "Every A is B, and everything which is not A is not B."

It is known then that the difficulty is entirely removed if we grant that "two lines which intersect are not both parallel to any third line," or, which is the same thing, that "through a given point not more than one line can be drawn parallel to a given line." The theory of Euclid being thus improved so far as it is capable of being done by a mere difference of statement, it remains to ask, 1. Whether assumption can be dispensed with altogether, and a direct proof of Euclid's axiom, or something equivalent to it, given? 2. If the preceding question be answered in the negative, can any more simple assumption be made the foundation of the theory?

The attempts to answer one or the other question in the affirmative have been very numerous, and have (without any exception but one in which new axioms of another sort are introduced) tacitly contained the defect which their authors were desirous of avoiding. The author of 'Geometry without Axioms' (General Perronet Thompson) has collected and commented on thirty instances, of which we here make a brief abstract, adding one or two more.

1. The axiom of Euclid in question. 2. Ptolemy; his proof assumes the symmetricality of parallel lines on one side and the other of any line which cuts both. 3. Proclus assumes that intersectors diverge infinitely from the point of intersection, and that parallels do not. 4. Clavius assumes that a line which is everywhere equidistant from a straight line, is itself straight. 5 and 6. Two demonstrations of Dr. Thomas Oliver (1604) assume Clavius's axiom. 7. Wolf, Boscovich, T. Simpson (in the first edition of his Elements), and Bonnycastle, define parallel lines as those which always preserve the same distance, which is Clavius's axiom in the disguise of a definition. 8. D'Alembert would define parallels as lines one of which has two points equidistant from the other, but acknowledged that he could not complete the proof of the axiom of Clavius. 9. T. Simpson (Elements, 2nd edition) proposed to assume that two lines, one of which has two points unequally distant from the other, must meet. 10. Robert Simpson proposed to assume that a straight line cannot first approach to and then recede from another, without cutting it. 11. Varignon, Bezout, &c., would define parallels as lines which make the same angle with a third line: if *a* third line mean *some one* third line, the difficulty remains just as before; if *any* third line, the difficulty is tacitly removed by an assumption. 12. Ludlam, Playfair, &c., recommend the axiom which we have also recommended, namely, that two intersecting straight lines cannot be both parallel to a third. 13. Leslie proposes to attain the same axiom in a sort of experimental manner, by making a line revolve about a point. 14. Playfair (in his Notes) proposes to assume that a straight line which turns completely round, and thus regains its first position, must turn through four right angles, whether it constantly revolves about one point, or whether the pivot of revolution changes. 15 and 16. Franceschini (1787) proposes to assume that the projections of a straight line on a line making an acute angle with it, increase without limit with the projected line. 17. Some have proposed to define parallels as "lines having the same direction," assuming it to be obviously contained in the conception of direction, that two similar

directions make the same angle with any other direction. 18. Mr. Exley (1818) proposes to assume that if four equal straight lines, each at right angles to the preceding, do not meet and enclose a space, a fifth such line would do so. 19. Dr. Creswell proposes to assume that through any point within an angle less than two right angles, a straight line may be supposed to be drawn cutting the two straight lines which contain the angle. 20. Professor Thompson makes it an axiom that "if a triangle be moved along a plane, so that its base may always be on the same straight line, its vertex describes a straight line equal to that described by either extremity of the base. 21. M. Legendre (in the earlier editions of his Elements) makes a direct appeal to the senses. 22. In the seventh edition he assumes (as in instance 15) that a magnitude increases without limit, where perpetual increase is all that is demonstrable. 23. In the twelfth edition he fairly brings the disputed proposition to rest upon the axiom, that if two angles of a triangle diminish without limit, the third (whatever the base may be) approaches without limit to two right angles, a proposition not admissible when, as in M. Legendre's final construction, the base at the same time increases without limit. 24. In a note to the same edition, he demands as an axiom that no straight line can be entirely included between two straight lines which make an angle less than two right angles, which may easily be shown to be nothing more or less than Euclid's axiom. 25. He attemps a proof of the last, which fails. 26. M. Legendre's analytical proof, which we shall presently examine. 27. M. Lacroix would confine the assumption of Euclid to the case in which one of the internal angles is a right angle and the other less. 28. M. Bertrand extends the use of the term equality; we shall afterwards examine his proof. 29. Mr. Ivory assumes a right to construct a series of triangles in a manner which cannot be certainly done unless an assumption as difficult as in (20) be made: and 30, Professor Young makes a modification of the preceding, which does not remove the difficulty.

For further information we may refer to the work from which the preceding abstract is taken. The author of it proposes his own system, the latent assumption of which is, that if equal straight lines make an angle, and other straight lines equal to them be attached to their extremities at the same angle, the remaining extremities of the second pair of straight lines will *not*[*] always meet.

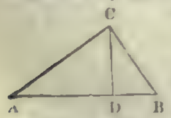
The same author, whose erudition on this subject would alone entitle any attempt of his to attention, has published a new view of the subject, in which he proposes to deduce the properties of the equiangular spiral, and to make them the foundation of a proof of Euclid's axiom. It assumes the doctrine of limits, and the theorem that velocities (in one case at least) are to one another in the limiting ratio of spaces described in the same times. Whatever may be thought of this method as evidence for producing conviction, we cannot take such an assumption as removing the geometrical difficulty, since, by the introduction of a totally new line, it leaps the conventional boundaries of geometry; to say nothing of the question which may fairly arise, as to whether the axioms of the theory of limits are not as difficult as that of Euclid.

Two proofs have been referred to as requiring further explanation: those of MM. Legendre and Bertrand. We take them successively.

The first assumes all that knowledge which is derived from algebra and the theory of algebraical operations. We premise that the theory of parallels may be strictly deduced, though not without some trouble, if it can previously be shown that the three angles of a triangle are equal to two right angles. Let there be a triangle of which the base contains c linear units, and the opposite angle C angular units, the other angles containing A and B units. Then it can be easily shown that any other triangle which has the same base c and the same adjacent angles A and B must be in all respects equal to the first: that is, c, A, and B being the side and adjacent angles of a really existing triangle, C is given when c, A, and B are given. There must then be some algebraical mode of expressing C in terms of c, A, and B, such as

$$C = \phi(c, A, B).$$

From such an equation, if it exist, c can be found in terms of A, B, and C, that is, the length of a straight line can be expressed by means of angles only. Now it is known that no equation can determine a magnitude by means of magnitudes no one of which is of the same kind with it: and the only way of avoiding this supposition is by supposing that c does not enter the equation at all, or that $C = \phi(A, B)$, so that the third angle of a triangle is given when the other two are given, whatever the side may be, *provided the triangle be known to exist.* Let there be a right angled triangle ACB, and let CD be perpendicular to AB; then the



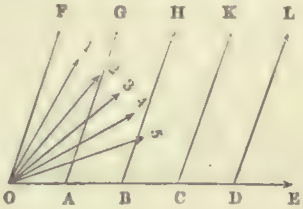
triangles ACB, ACD, have a common angle at A, and a right angle in each: consequently their third angles are equal, or ACD = ABC. Similarly DCB = CAB; whence the angles at A and B are together equal to a right angle. And if the two acute angles of a right angled triangle be equal to one right angle, it is readily shown that all the three angles of any triangle are equal to two right angles.

It is not our intention to go fully into the objections which have been made to this proof, nor into Legendre's answers; all which may be found in the notes to Sir David Brewster's translation of Legendre. It has the disadvantage of being founded upon a science which requires more and harder axioms than geometry itself, and of which the particular process employed, namely, inversion of a function, is in many cases full of unexplained difficulties; while it has the advantage of not appealing to any new notions of space. As an illustration of the connection between algebra and geometry, it must always be valuable: but we suppose no one would think of making it the foundation of geometry. Some objectors imagined that Legendre would infer that a base c, with two adjacent angles together less than two right angles, must be the base of a triangle; or that because the formula applies wherever there is a triangle, that there must be a triangle wherever the formula applies. If this were the case, undoubtedly they were right in saying that Legendre did in fact assume Euclid's axiom: but if, as we apprehend, he would have applied the proposition thus proved of existing triangles, to the proof of Euclid's axiom, he should certainly have stated his intention more distinctly in his reply. It seems to us that he took it as admitted on all sides how to deduce Euclid's axiom, while his opponents imagined that he considered himself as having proved that axiom.

It is of much importance, in connection with Legendre's view, to remember the point mentioned at the end of ANGLE, namely, that angle, of all magnitudes, is the only one of which number is a function, and the converse.

The proof of M. Bertrand is as follows:—Let it be granted that two spaces, *whether finite or infinite*, are equal,[*] when one can be placed upon the other so that any point whatsoever of either lies upon a point of the other: that is, let it be legitimate to say, of the word equal as thus used, that spaces which are equal to the same space are equal to one another. Granting this, it is easily shown—1, that the infinite spaces of equal angles are equal; 2, that of two angles, the infinite space contained in the greater is greater than the infinite space contained in the less.

Let there be two lines, OF, AG, making with OA internal angles FOA, GAO, equal to two right angles. Then OF and AG are parallel.



Take AB, BC, CD, &c., each equal to OA, and make the angles HBC, KCD, LDE, &c., all equal to FOA or GAB. Let all lines with arrowheads be produced without limit in the direction to which the arrowhead points. Then if OA be placed on AB, the lines OF and AG will in their new positions coincide with AG and BH, or the infinite space FOAG is equal to the infinite space GABH: and similarly HBCK, KCDL, &c., are all equal to one another and to FOAG. But it is obvious that no number of these spaces, however great, will fill up the infinite space of the angle FOE. Now let a line O1 be drawn in such a manner that 1OA and GAO are together less than two right angles; whence O1 falls nearer to OE than does OF. Take FO2 double of FO1, FO3, treble of FO1 and so on: whence, since of two quantities which bear a ratio, the less may be multiplied so as to exceed the greater, some multiple of FO1 must be greater than FOE, whence some multiple of the infinite space FO1 is greater than the infinite space FOE. But no multiple of FOAG will be so great as FOE; whence the infinite space FO1 must exceed the infinite space FOAG. Therefore O1 produced must cut AG; for if not, the space FO1 would be entirely contained in FOAG, and the former could not exceed the latter.

We have not noticed the numerous attempts at the solution of the difficulty which proceed by tacit assumption or illogical process, under the pretence of avoiding the axiom of Euclid, without substitution of any other. We shall conclude this article with an account of a result contained in a paper, by Legendre, in the 12th volume of the 'Memoirs of the Institute,' being his latest attempt at the solution of the problem. It is what he properly styles a geometrical translation of the analytical proof already noticed, and its chain of reasoning proceeds through three propositions.

---

[*] In the edition of 1833, this assumption was explicitly made. A writer in the 'Journal of Education' (vol. vii. p. 105), having pointed this out, the words "provided the straight lines do not meet" were added (in the edition of 1834) to the enunciations of the leading propositions of the proof. This certainly removes the difficulty from the propositions themselves, but throws it upon their consequences; and the final result only remains proved, provided those lines do not always meet: that is, the proposition that they do not always meet, still remains an axiom. The work is well worth the perusal of the student, though we have no doubt whatever that in respect to the theory of parallels it is no amendment of Euclid.

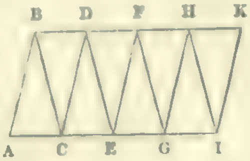
[*] The author of 'Geometry without Axioms' cites Plato for the axiom that equality is only to be predicated of finite magnitudes. But withon tlooking at the authority of Plato, or any one else, it is for the reader now to ask himself whether he can, by comparing the infinite spaces contained in equal and unequal angles, obtain a distinct conception of equality, of greater, and of less: if so, the proof of M. Bertrand must be admitted by him; if not, no one has a right to demand his acquiescence. We are inclined to think that it *is* a proof to some, but not to others; to us it certainly is a proof. But we do not contend for the admission of considerations respecting infinity into elementary geometry: we should hold such a plan altogether opposed to every principle of sound teaching.

1. It is impossible that the sum of the angles of a triangle can in any case exceed two right angles.

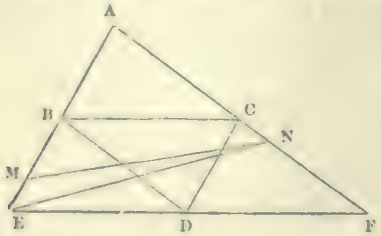
2. If there be any one triangle which has angles together equal to two right angles, the same must be true of all triangles.

3. If the angles of a triangle be not equal to two right angles, then angles alone may be made to determine a straight line.

1. If it be possible, let there be a triangle B A C having its angles together greater than two right angles. In A C produced take C E, E G, G I, &c. each equal to A C, and make the angles D C E, F E G, &c. each equal to B A C, and let C D, E F, &c. be each equal to A B. Join B D, D F, &c. which are not known to be in the same straight line, though they are so. Then the triangles D C E, F E G, &c. are severally equal in all respects to B A C. And because the angles at A, B, C, are together (by hyp.) greater than two right angles, and two of them are equal to two of the angles at C, it follows that the angle A B C is greater than B C D, whence A B and B C being severally equal to D C and C B, it follows that A C is greater than B D. Similarly C E is greater than D F, &c., whence A I exceeds B D F H K by as many times the excess of A C over B D as A C is contained in A I. Now however small this excess may be, it may be multiplied until the multiple exceeds twice A B, or A B and K I together. That is, A I, one side of a figure, may be made greater than A B, B D, D F .... K I, the sum of all the other sides; which is absurd. Hence, it is not true that the angles of any triangle are together greater than two right angles.

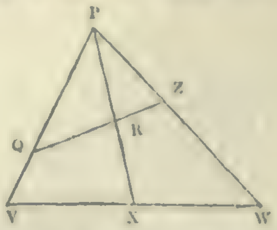


2. Let there be any one triangle A B C in which the sum of all the angles is two right angles. Make the angle B C D = A B C, and C B D = A C B, whence the triangle B D C is in all respects equal to A B C. Produce A B and A C each to double of its length, and join E, D, and D F. The angle C B E being equal to B A C and A C B together, and C B D being = B C A, it follows that E B D = B A C; whence the triangle E B D is in all respects equal to B A C, and the same, for similar reasons, is D C F. Hence the three angles at D are severally equal to those of the triangle A B C, or to two right angles; and thus E D F is a straight line, and A E F a triangle equiangular with A B C, and therefore having angles equal to two right angles. Or, if there be any such triangle, there is another of the same sort with double sides and the same angles; and since this process of doubling the sides may be repeated to any extent, it follows that, if there be any other given triangle, a triangle can be found with longer sides, and having the sum of its angles equal to two right angles.

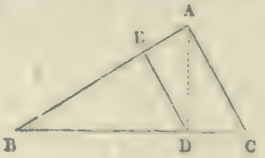


Next, any triangle A M N which has the angle A, must have the sum of all its angles also equal to two right angles. Continue the preceding process until the triangle A M N is completely inclosed, say in A E F, and join E, N. Then all the angles of the three triangles A M N, M N E, N E F, make up the angles at A, E, F (two right angles), those at M (two right angles), and those at N (two right angles); six right angles in all. Consequently each set of angles, in each triangle, must be equal to two right angles; for all three sets making up six right angles, no one set can fall short of two right angles, without another set exceeding it, which has been shown to be impossible.

Lastly, on the preceding assumption (namely, that there is one such triangle), every triangle has the sum of its angles equal to two right angles. Let A B C be the one triangle, as before, and let P Q R be any triangle not equiangular with A B C; one of its angles must be less than one of the angles of A B C; for if not, the sum of the angles P, Q, R would be greater than that of A, B, C, or greater than two right angles. Let it be that P is less than A, and make Q P Z equal to B A C, constructing, by the preceding process of doubling the sides, a triangle V P W containing P Q R. Then since P V X has an angle (at V) common with P V W, the angles of P V X are together equal to two right angles, and because P V X has an angle in common with P Q R, the angles of P Q R are also equal to two right angles. Hence, if any one triangle have its angles equal to two right angles, the same must be true of all triangles whatsoever.



3. If then we deny the preceding truth in the case of any one triangle, we must deny it in the case of all. Let it then be universally denied; and, taking any triangle A B C, take a point D, at which make the angle B D E = B C A. Then the angle B E D must be greater than B A C; for if not, D E A and E A C are at least equal to two right angles, and, E D C and A C D being together equal to two right angles, the angles of the triangles E D A, A D C, are together at least equal to four right angles, which is denied. For it is denied that either set is equal to two right angles, and it has been shown that neither set can be greater. In like manner it may be shown that if D move from C to B (the angle B D E being always = B C A), the angle B E D must continually increase, and can therefore only have a given value for a thereby determined value of B D. That is, by assigning the angles B, D, E, the side B D can be absolutely laid down. Now since angles might be given in numbers (taking the right angle, which is absolute, as a unit), it therefore follows that the length of a straight line might be handed down from generation to generation, by means of numbers only, without any dependence on a *linear* unit. This is the same conclusion as follows from the analytical proof, against those who would deny its conclusions.



We consider the preceding process as containing the most remarkable addition which has been made to the theory. With regard to the whole question, we do not consider the difficulty as one of a different kind from that of the quadrature of the circle or the trisection of the angle. In the earlier stages of mathematical investigation, all that was not evidently impossible was attempted, and failure was, properly and modestly, attributed to the want of sagacity in the investigators. In the instance before us, the object was to deduce positive properties from a purely negative definition, involving, be it observed, the idea of infinity. For if we say that parallels are lines which never meet, however far produced, we must, in the hypothesis "let A B and C D be two parallel lines," contemplate every point of both, however remote from A and B. The demonstration of M. Bertrand appears to us to assume considerations which are indispensable to the direct treatment of this negative definition; nor can we imagine the positive deduction of properties from the assumption of lines which never meet, without making their intervening space, as compared with other spaces, an object of reasoning. And even if the preceding process of M. Legendre should be allowed, so far as proving that one triangle only need be shown to have the sum of its angles equal to two right angles, and should the final theorem be ultimately completed by a less objectionable third process (of which we do not entirely despair), it may be doubted whether right reasoning will be promoted by the arbitrary rejection of notions intimately connected with those which are necessary for the perfect conception of a definition. On this the whole question must at last turn: it will readily be granted that a studied exclusion of a particular figure (for instance, of the equilateral triangle) would be no real gain to the strictness of geometry, even though it should be shown that the whole of Euclid might be established without it. The new considerations brought forward by M. Bertrand have not yet received the degree of attention which we will venture to prophesy must yet be given to them. When they have been maturely discussed, the following question will arise:—In admitting the notion and definition of parallels, and rejecting the comparison of their intervening spaces with angular spaces, are we, or are we not, in the position of those who admit one notion, while they exclude another which is as much of kin to the first as that of an equilateral triangle to any other triangle? We should be sorry to see this question settled either way without such an examination of the nature of our ideas of magnitude, and in particular of the connection of finite and infinite, as has not yet been made. But even if our question should be resolved in the affirmative, it does not follow that comparisons of infinites can be successfully introduced into elementary teaching.

PARALLELS, in the attack or siege of a place (SIEGE), are wide trenches affording the besieging troops a free covered communication between their batteries and approaches, and a protection for the guard of the trenches and the covering parties in the day time. What were in former times termed lines of contravallation are now termed parallels. There are usually three or four parallels made in the attack of a place, though of course the number will depend wholly on the strength of, and the artillery possessed by, the garrison; the saliency of its main works, and of its outworks and detached works, should it possess any; the vigour of the defence and the nature of the ground in the neighbourhood, whether providing good natural cover for bodies of covering troops or not. Though the siege of different places will vary much according to these points, methods of attack are laid down in works on fortification on certain assumptions, in order to give an idea of the general method, and from which to deduce a standard of strength of different systems. In these there are generally three parallels; the first at 600 yards from the place, another at about 300 yards, and a third at the foot of the glacis. The second parallel is constructed by *flying sap*, the third by regular sap, while the first, being supposed out of the range of musquetry, grape-shot, and canister, by ordinary trench-work. These distances and methods may be much modified in practice, especially by the introduction of arms of precision, but as an assumption either for instruction or for comparing different systems they are still retained. The method of tracing, &c., will be found under SIEGE.

PARALYSIS (a Greek word, *παράλυσις*, which signifies literally a "loosening" or "relaxation") is the diseased condition in which the natural power of sensation or motion is lost in any part of the body.

The principal forms of paralysis are dependent on the fact that although most of the nerves distributed through the various parts of the body contain filaments for performing the functions of motion and sensation within the same sheath, yet the two orders of filaments are distinct in their origins and arise from separate portions or tracts of the brain and spinal chord. If a sensitive nerve, or the tract of nervous matter from which the sensitive nerves of any part arise, be destroyed or seriously diseased, there will be a loss of sensation in that part, but its natural power of motion will remain; if the same injury befal a motor nerve, or a centre of origin for motor nerves, the part supplied therefrom will lose its motion, but retain its sensibility; and if a mixed nerve, or both nervous centres simultaneously, be affected, there will be a loss at once of sensation and of motion. Hence we have two distinct kinds of paralysis—loss of sensation, which is sometimes called *anæsthesia*, and loss of motion, to which the term paralysis, or palsy, is by some exclusively applied.

Each of these varieties of paralysis may vary in its degree of severity, or in the extent of the part of the body which it affects. For example, either kind may be *complete* or *incomplete*: in the former, the sensation or loss of motion, or both, are completely destroyed; in the latter, they are only impaired. In its varieties of extent, paralysis of sensation may affect either a single nerve, as in loss of sight when dependent on disease of the optic nerve [AMAUROSIS]; in loss of smell, or anosmia, from affection of the olfactory nerve; in deafness, from disease of the auditory nerve; and loss of taste, from disease of the nerves appropriated to that function: or it may affect the sensitive nerves of a limb or of a variable portion of the body. In like manner paralysis of motion may affect a single muscle, as in *ptosis*, or dropping of the eyelid, from disease of the third nerve; or it may occur in a part of the muscles of the face, or the muscles of one or more limbs, or of a part of the trunk and limbs. Lastly, whole regions of the body may be paralysed; and of these cases the chief varieties are, *hemiplegia*, in which one side—half of the body—is deprived of sensation or motion, or of both; *paraplegia*, in which the lower part of the body is paralysed, while the upper retains both sensation and motion; and general paralysis, in which the loss of nervous power extends over nearly every part of the body.

Other varieties of paralysis are described from peculiar circumstances in their cause or symptoms; as *lead*-palsy, which is produced by the influence of lead, either locally applied, as to the hands of painters, or received into the system generally; *creeping*-palsy, which, commencing in a limited part of the body, gradually extends over a large portion of it; *shaking*-palsy, in which the loss of motion being incomplete, any attempt at its exercise is effected by a trembling unsteady action, like that of a fatigued muscle.

The conditions under which these various forms of paralysis arise are numerous. Its most common and general causes are those which mechanically destroy that condition which is essential either to the conduction of sensitive impressions to the brain and to their perception by the mind, or to the conveyance of the stimulus of the will through the nerves of motion to the muscles. Thus pressure on the brain, by a fracture and depression of the skull [HEAD, INJURIES OF], or by a large effusion of blood [APOPLEXY], or by large tumours, or an excessive fulness of the arterial or venous system of the brain [ENCEPHALITIS; MENINGITIS] may, by preventing the free circulation of the blood through every part of its substance, produce general paralysis. Disorganisation of the brain by softening or other excessive change of structure has the same effect, but often in a less degree, producing not a complete loss, but an impairment of nervous power. Injuries of the same kind affecting only one side of the brain produce hemiplegia, the loss of power existing on the side of the body opposite to that on which the brain is compressed, in consequence of the decussation of the nerves which takes place at the medulla oblongata. [BRAIN, NAT. HIST. DIV.]

In like manner a similar compression of the spinal cord in any part will produce a paralysis of all the parts of the body whose nerves come off below the level of the injured part; and a similar obstruction applied to a single nerve will affect only that part which it supplies. The effect is the same, whatever be the nature of the cause preventing the performance of the functions of the nerves or their centres; the results of each differing only in the suddenness or slowness, or the degree of intensity with which its symptoms are produced.

There are some other but rarer and generally less serious cases of paralysis, in which no material change is discoverable in the structure of the nervous system. These are called functional or idiopathic paralysis; but it may be reasonably doubted whether they do not all, or for the most part, depend on some alteration not yet discovered, and perhaps inappreciable by our present means of investigation. Such cases occur in some anomalous forms of nervous diseases, as in hysteria, and appear to be connected by sympathy with disorder of the uterine or digestive functions; they are also not unfrequently produced by the introduction of poisons, as in those who work with lead or mercury.

General paralysis, in which all sensation and voluntary motion are impaired or lost, is most commonly the result of apoplexy, or of severe injury to the head, producing concussion or compression of the brain; and indeed it may be said to exist in all cases of complete coma, or insensibility. More rarely it is produced gradually; the patient losing in succession the power of motion in all his muscles, and at last existing only with an internal life, but disabled from all active communication with the external world. This state is usually the result of disease of the brain or spinal cord gradually spreading through their substance; and especially of disease of the latter spreading upwards. It not unfrequently comes on in the inmates of lunatic asylums.

The most frequent if not the only cause of paraplegia is injury or disease of the spinal cord; and this may originate in its own structure, or be produced by injuries or diseases of the vertebral column or other parts surrounding it. Paraplegia, when the result of disease, commonly affects first the lower extremities and the parts below the level of the haunches, because the first part affected in the greater number of diseases is the lower portion of the spinal cord, from which the nerves supplying the lower extremities and pelvic organs are derived. When produced by injuries of the vertebral column however, the paraplegia may from the first affect the body to a much higher level; its extent being always determined by the height in the vertebral column at which the injury is inflicted. In either case the disease, whether original or consequent upon injury, tends to spread up the cord; and with a corresponding progress, the paralysis rises up the trunk, and affects successively the chest and arms, terminating in death when the disease has reached the origin of the phrenic nerves, upon which the movements of the diaphragm depend.

In this form of paralysis, when all sensation and voluntary motion are destroyed, involuntary movements are produced by irritating the skin of the insensible parts. These motions depend on the reflex action of the spinal cord [NERVOUS SYSTEM, NAT. HIST. DIV.]; the power of conducting impressions to and from the brain is lost, but the power which the cord possesses of exciting motions when impressions are made upon it, remains. The patient thus affected is indeed, as far as his nervous system is concerned, in the same condition as a beheaded animal; and the actions produced by irritating the parts below the divided or injured portion of the cord are of the same kind as those observed after decapitation.

In paraplegia the parts deprived of nervous connection with the brain are, even more than in any other form of paralysis, liable to mortification when long subjected to pressure; and hence the sloughing of the back, which so commonly tends to shorten the patient's life. The sensibility to the pain produced by long-continued pressure being destroyed, the patient would not be inclined, even if he were able, to make those frequent changes of position by which a healthy person avoids its dangers.

Hemiplegia, in which the paralysis is confined to one side of the body, usually affects (as paraplegia does) the sensitive and the motor nerves simultaneously. This is by far the most frequent form of paralysis, and is that by which those popularly called paralytic are usually affected. Hemiplegia generally occupies exactly one-half of the body, the middle vertical plane separating the healthy from the paralytic portion. It is at once easily recognised in any patient by the flatness and smoothness of the affected side of the face, by the angle of the mouth being drawn over towards the opposite side, and by a general *wry* position of the features. The arm hangs powerless by the side; and in walking, the patient drags the affected leg after him, or, raising it from the groud by depressing the opposite side of the pelvis, lets it swing forward with its toe pointed towards the ground like a pendulum. Hemiplegia is most frequently the consequence of apoplexy [Apoplexy], remaining after the patient has recovered from the complete insensibility or general paralysis by which the seizure was at first followed. More rarely it appears to rise from congestion or disorganisation of the brain, and is not preceded by any fit, but is developed by degrees from slight to perfect loss of nervous power.

The varieties of paralysis, in which single and small portions of the body are affected, do not in general continue permanently limited to the part first attacked, but are often precursors of the more general affections already described. The most important forms, and those in which the paralysis most frequently remains for a long time local, are those in which the eyelids or muscles of the eye, and those in which the muscles of the face, are affected.

In paralysis of the muscles of the eye, the most commonly affected are the elevator of the upper eyelid and the orbicular muscle of both the eyelids. When the former loses its power, the eyelid drops, and the eye is constantly more or less closed; when the latter is affected, the eye cannot be shut, and remains permanently wide open. The dropping of the upper eyelid (or ptosis) is dependent on a disease or injury of the third pair of nerves, and is usually accompanied by a paralysis of some of the muscles of the eyeball which are supplied by the same nerve; so that the position of the eye is altered, or it cannot be freely moved. The permanent openness of the eye is the result of disease of the seventh or facial nerve, or of its branch supplying the orbicular muscle; sometimes this latter branch alone is implicated; but more frequently the whole trunk is affected, and there is coincident paralysis of all the muscles of the face. As far as regards their influence on vision, both cases are almost equally injurious; the first by placing a veil constantly over the front of the eye; the second by destroying the power by which particles of dust, &c., are removed from the surface of the eye, and thus leaving it exposed to the dangers of constant irritation and inflammation.

In paralysis of the face many different conditions are observed, according to the nerve which has been diseased or injured. The sensation of the face depends entirely on the sensitive or larger portion of the fifth pair of nerves [Brain, in Nat. Hist. Div], the motion of its muscles on the seventh or facial nerves, and the motion of the muscles of mastication on the motor or small portion of the fifth pair. Now if either of these three nerves or their sources in the brain be separately injured, the paralysis will be limited to a loss of sensation, a loss of the motion of the muscles of the face, or a loss of the motion of those of the jaw, on the side affected. In the most frequent cases of affection of the fifth nerve, both its sensitive and motor portion are injured, and there is both a loss of motion of the muscles of the jaw and a loss of sensation of the whole of the skin of one side of the face.

Lastly, a limb, or a part of a limb, or a single muscle or set of muscles in any part of the body, may be paralysed. In some cases such an affection is only a sign of disordered digestion, and thus they occur chiefly in children; in others it exists in what is called general nervousness, as in hysterical women, who, with many other strange disorders, sometimes lose the power of swallowing or speaking. Most frequently, however, these forms of local paralysis depend on injury of the nerves of the part, which are compressed by tumours or involved in some diffused disease.

An important class of local paralytic affections includes those in which recent investigations have detected the sources of many cases of congenital or acquired deformity, such as club-foot, curvature of the spine, squinting, &c. In these, one or more muscles of a limb or organ being from birth or from childhood weak or powerless, its antagonist muscles draw the part into an unnatural position, and hold it there firmly and permanently fixed. One of the most important achievements of modern surgery is the cure of these affections by the division of the contracted muscle or its tendons. [Contraction.]

These, however, are the only cases in which general rules of treatment can be laid down. The varieties of causes from which paralysis may arise, afford sufficient evidence that its treatment in different cases must vary greatly. It cannot indeed be said to be a disease of itself, since it is only a sign of some disorder of the nervous system, which is often seated at a distance from the part whose motion or sensation is lost. This disorder, also, is of no definite kind, but may be the result of hæmorrhage, or inflammation, or slow structural change of the nervous substance; or it may be produced by the pressure of fractured bones, or tumours, &c. In each case, therefore, the cause of the paralysis must be treated before there can be any expectation of removing its effects.

PARA'METER. This term was first used in reference to the conic sections only, in which it was synonymous with latus rectum; that is, the perpendicular drawn to the axis through a focus, terminated both ways by the curve, was the parameter of the curve. It was afterwards used to denote any straight line or even numerical co-efficient, by the value of which one individual curve of a species may be distinguished from the rest. Thus the curve whose equation is $y = ax + bx^3$ has two parameters, a and b. This last phraseology was never in very general use, and is now preserved only in questions in which what is called the variation of parameters is to be employed. Thus when in the planetary theory the motion of a planet is ascertained by determination of the variation of the instantaneous ellipse [Gravitation; Orbit], and of the motion in that ellipse, in contradistinction to determining the motion in longitude and latitude separately, the method of variation of parameters was said to have been employed. But the *parameters* of the orbits are now generally called their *elements*; and the first term is little used in astronomy, though it occurs frequently enough in works on the differential calculus to require notice in a work of reference.

PARAMIC ACID. This name has been given to a white crystalline precipitate obtained by dissolving paramide in ammonia and then pouring the solution into hydrochloric acid. Its composition and even its existence are somewhat doubtful.

PARAMIDE (C_8HNO_4), *Mellimide*, is formed when mellitate of ammonia is heated in a retort to about 320°. It is accompanied by another body called *euchroic acid*. Paramide is a solid yellow substance, which when long boiled with water is changed into a bimellitate of ammonia.

PARAMORPHIA, *paramorphine*. [Opium, Alkaloids of.]

PARAMOUNT. [Title.]

PARAMUCIC ACID. [Mucic Acid.]

PARANAPHTHALIN. [Naphthalic Group.]

PARAPET (from the Italian *parapetto*, compounded of the Greek preposition παρὰ, "against," and *petto*, "breast;" in German, *brustwehr*), a low or breast-high wall or fence, to serve as a protection on bridges, terraces, platform roofs, &c. In Italian architecture, parapets are generally balustrades. In Gothic architecture, the parapet is a continuation of the wall carried up above the edge of the roof, and finished by a coping; unless machicolated, in which case it projects and overhangs the walls below. [Machicolation.] In the Romanesque buildings of Italy there is seldom any parapet, the eaves of the roof finishing the elevation. The same is frequently the case in the Norman style, or else the parapet is quite plain; whereas in Pointed Gothic it is commonly embattled, even in ecclesiastical buildings, and both the battlements and the crenelles or spaces between them have usually moulded copings. In the Third Pointed or Perpendicular style, parapets and battlements are either pierced or enriched with panels. East Basham manor-house is a fine specimen of such decoration in domestic architecture. (Pugin's 'Goth. Examples,' vol. i.) The perforated or open-work parapets of quatrefoil ornaments and other carved patterns often form a very rich feature in ecclesiastical and collegiate buildings of Third Pointed date. At a later period instances occur of open-work for such purpose, forming the letters of some motto, date, or inscription. In Elizabethan buildings open-work parapets, forming various fantastical devices, are common.

PARAPET, in Fortification, is generally an embankment of earth which is formed either on the natural ground or on the upper surface of the rampart of a fortress or outwork. In the latter case the parapet rests on that part of the rampart which is nearest to the exterior of the work, the terreplein, or nearly level part on the interior side, being occupied by the artillery or left free for the movements of the defenders. Parapets of brick or stone are sometimes constructed for works which are masked by others in their front, or on heights, or on the sea-coasts; but in other circumstances they would be improper, because the splinters detached from such materials by the enemy's shot are dangerous to the defenders, whereas the shot sinks into earth without doing further mischief.

The height of a parapet above the ground, or above the terreplein of a rampart which it surmounts, is about 7½ feet, in order that it may effectually cover the defenders behind it. In its mass are cut the embrasures through which the guns are fired; and a banquette, or step, about 3 feet high and 4 feet broad is formed, usually of earth, at its foot, on the interior side, in order to enable men, by standing on it, to fire over the upper surface. The form of a transverse section of a rampart, surmounted by a parapet, is represented in *fig.* 2, Bastion; the parapet with its banquette being that which occupies, on the right hand side of the figure, rather less than the upper half of the space between the dotted lines.

The exterior face of a parapet of earth is generally formed in a plane making an angle of 45 degrees with the horizon, in order that the earth may stand unsupported; the superior surface, which varies in breadth from 3 feet to 25 feet according to the nature of the shot which it is intended to resist (from musket bullets to the balls discharged from the heaviest ordnance), has its exterior crest or edge lower than the other by about one-sixth of the breadth of that surface. It is recommended that the depression of the slope should not bear a greater proportion to the breadth, lest the upper part of the parapet should by its acuteness be weakened; but the general rule is that the plane of the superior slope should, if produced, meet the counterscarp line of the ditch in front, in order that the enemy, at the time of an assault, and when detained by the obstacles there, may be completely exposed to the fire of musketry from the parapet. The interior face of the parapet is frequently formed in a plane passing through the crest, and, at the terreplein of the banquette, or at the foot of the parapet if there is no banquette, deviating from a vertical plane passing through the same crest about one-third of the height of the slope. By this inclination the earth, when reveted with fascines or sods, and even without any revetment, will support itself for a time, while a man, by leaning a little forward, is enabled without inconvenience to fire over the parapet.

Occasionally parapets of field-works have been formed with the earth obtained by excavating the ground in the interior; and, in this case, the crest of the parapet may be only 3 or 4 feet above the exterior ground. Such a construction is admissible, however, only when the site of the work is several feet higher than the ground which the enemy may occupy, since otherwise the defenders, except when close behind the parapet, would be exposed to his fire. Again, should the ground about the spot to be fortified be higher than that spot, the crest of the parapet must have a greater height than 7½ feet, in order that the defenders may be sufficiently covered by it: but in general the parapets of field-works cannot be raised more than 14 feet above the ground; since a man can scarcely throw earth with a spade to a greater height than 7 feet, and a greater height than 14 feet would require, above ground, more than two rows of shovellers, one row 7 feet above the other, besides one row, or two rows, at an equal interval in the ditch; and it is seldom that the numerical strength of a working party is sufficient to allow such a disposition to be made.

The earth used for forming the parapets should be as free as possible from stones or gravel, or these should be put into the centre of the mass, in order to avoid the accidents which might arise from the dispersion of the stones when shot or shells strike; and the slopes, as well as the banquettes, when time permits, should be covered with turf.

PARAPHERNA'LIA. This term comprehends the dress and ornaments of a wife which she occasionally wears, and which she is entitled, under some limitations, to retain after her husband's decease. It cannot be accurately stated how much a wife may claim as her paraphernalia, for this will depend on the rank and fortune of the husband and wife. A widow is entitled to retain as paraphernalia ornaments which she has received from her husband, provided she has worn them occasionally. The wife cannot give or bequeath such paraphernalia during her husband's life, nor can her husband bequeath such paraphernalia so as to deprive her of them; but he can sell them or give them. The wife's paraphernalia are liable to the payment of the husband's debts, unless the articles were given to her by a stranger before marriage or after marriage: in such case the articles are considered as gifts to the separate use of the wife, and are accordingly neither at the disposition of the husband nor liable to the claims of his creditors; but if such gifts are to be considered as the separate estate of the wife, they are not properly paraphernalia.

The widow is entitled to her paraphernalia in preference to any claim of legatees; and if specialty creditors of her husband have taken her paraphernalia for payment of their debts after the personal estate is exhausted, she has a right to reimburse herself out of the real estate which has descended to the heir.

The term paraphernalia is derived from the Greek *parapherna*, a term which the Roman lawyers adopted to express what in their own language could not be expressed by a single word, and which was expressed by the periphrasis of *præter* or *extra dotem*. The parapherna comprised the things which the wife brought to the husband's house, and which were not part of her *dos*. The common practice at Rome was for the woman to make out a list of such things as she used, clothing, &c., which list was signed by the husband, as an acknowledgment of receiving them, or at least of receiving them into his house. This practice, derived from the Roman law, is still in use in some countries of Europe. The husband did not obtain the ownership of the things included in such list, and in case of a separation, they were restored to the wife: if they were not restored, she could recover them by an action framed according to the circumstances of the case. ('Dig.,' 23, tit., 3, s. 9.) It must be remembered that the Roman *dos* is a different thing from the English *dower*, though some English writers on law have confounded them. (Roper, 'Law of Husband and Wife,' "Paraphernalia.") [MARRIAGE.]

PARAPHRASE (from the Greek *παράφρασις*). A paraphrase partakes of the nature both of a version, if the work paraphrased be in a foreign language, and of a commentary. Its object is to express the full sense contained in the words which are paraphrased, by the introduction of circumlocutions, explanatory clauses, and expansions of the author's meaning. A paraphrase, if well and honestly executed, is an excellent mode of giving a connected interpretation of a whole work. The faults to which this sort of commentary is most liable are an alteration of the author's sense, and a degree of weakness and tediousness resulting from the use of unnecessary words.

PARAPLEGIA. [PARALYSIS.]

PARASANG (*ὁ παρασάγγης*), a Persian measure of length, which, according to Herodotus (ii. 6; v. 53; vi. 42), was equal to 30 stadia and if we reckon eight stadia as equal to one English mile, the parasang was consequently equal to nearly four English miles. Hesychius and Suidas also give the length of the parasang at 30 stadia; and Xenophon must have calculated it at the same length, as he says ('Anab.,' ii. 2, s. 6) that 16,050 stadia are equal to 535 parasangs (16,050÷535 = 30). Pliny ('Hist. Nat.,' vi. 30), however, informs us that the length of the parasang was reckoned differently by different authors; and Strabo states (xi., p. 518, Casaubon) that some reckoned it at 60, others at 40, and others at 30 stadia. The Arabic geographers (see Freytag, 'Lex Arab.,' sub Farsakh) reckon it equal to three miles. The Rev. G. Rawlinson remarks (in a note in his edition of Herodotus, 1859), that the parasang, like the farsakh, was originally a measure of time, not of distance, and consequently varied according to the nature of the country passed over. He agrees, however, in the general conclusion that it averaged about three and a half to four English miles.

Parasang is a Persian word, and is derived from the ancient farsang, which is pronounced in modern Persian, ferseng. It has been changed in Arabic into farsakh. Various etymologies of this word have been proposed. The latter part of the word is supposed to be the Persian *seng*, a stone, and the word might thus be derived from the stones which were placed to mark the distances in the road. Bohlen (quoted by Rödiger) supposes the first part of the word to be the preposition *fera*, and compares the word with the Latin *ad lapidem*.

PARATHERMIC RAYS. Photographic processes are considerably expedited by the application of a gentle heat, and the active agent is supposed to consist of rays which are found in and below the red and orange of the solar spectrum, and which are emitted by bodies heated just below redness. These parathermic rays probably bear the same relation to the true calorific rays as those which produce chemical phenomena do to the luminous rays.

PARATHIONIC ACID ($C_4H_6S_2O_8$). An acid of little importance, isomeric with sulphovinic or ethyl-sulphuric acid. [ETHYL.]

PARATONNERRE. The French term for a LIGHTNING CONDUCTOR.

PARCÆ (*Μοῖραι*), the Fates, were goddesses who were supposed to preside over the destinies of man. In Homer we only read of one deity, *Μοῖρα* or *Αἶσα*; but in Hesiod and all succeeding poets we read of three Fates: Clotho (*Κλωθώ*), the "Spinster;" Lachesis (*Λαχέσις*), the "Distributor;" and Atropos (*Ἄτρωπος*), the "Unchangeable." In one passage Hesiod ('Theog.,' 904) calls them the daughters of Zeus and Themis; and in another ('Theog.,' 217), the daughters of Night, which agrees with the statement of Cicero ('De Nat. Deor.,' iii. 17), who makes them the daughters of Night and Darkness (Erebus). This contradiction seems to have arisen from the different notions entertained by the ancients respecting the relative power of Zeus and the Fates, since they were sometimes represented as ruling the gods and Zeus himself, and at other times as merely carrying into effect the determinations of Zeus. In the ancient Greek writers, and especially the tragic poets, the gods themselves are represented as subject to the decrees of fate; but in later times the Fates appear to have been generally regarded as subject to Zeus. Thus we learn from Pausanias (v. 15, s. 4; x. 24, s. 4) that Zeus was worshipped both at Olympia and Delphi under the name of *Μοιραγέτης*, or "Leader of the Fates," which title was also applied to Apollo at Delphi. (Paus., x. 24, s. 4.) Pausanias, in describing (i. 40, s. 3) a celebrated statue of Zeus at Megara, on the head of which the Fates (*Μοῖραι*) were placed, remarks that this was done because destiny (*τὴν πεπρωμένην*) is obedient to Zeus alone.

The Fates are usually spoken of by the Greek and Roman poets as spinning the destinies of men ('Il.,' xx. 128; 'Od.,' vii. 197); and according to mythologists, each of the three presided over different periods of human life: Clotho over the beginning, Atropos the end, and Lachesis the general course of the life of each individual. Apuleius ('De Mundo,' p. 280, Bipont), whose opinion however can scarcely be regarded as representing the popular belief upon the subject, assigns a different office to each of the Fates. Atropos he regards as the Fate of past time, Lachesis of future, and Clotho of present events. In Greek art the Fates are sometimes represented as matrons winged. In some instances Atropos has a style, holds scales, or points to the hour on a sun-dial, or is cutting the thread of life; Clotho is spinning; Lachesis holds a roll, or is writing.

There was a temple at Lacedæmon sacred to the Fates (Paus., iii. 11, s. 8), and there were also altars sacred to them in the neighbourhood of Sicyon. (Paus. ii. 11, s. 4) They had also in later times a small temple at Rome in the eleventh district (regio) of the city (Onuphr. Panvin. apud Rosin., i, c. 13); but their worship seems to have prevailed at Rome to a very small extent.

PARCENERS, or COPARCENERS, are so called because the lands of which they are parceners may be partitioned or divided among them. There may be parceners by common law and parceners by custom.

As to parceners by common law, if a man dies intestate seised of lands in fee, and leaves only daughters, the lands will descend equally to all the daughters; or if he has no daughters and no brothers, the lands will descend equally to all his sisters, if he has any; and if there are no nearer heirs, the lands will descend to his aunts. The descent is the same if a man dies seised of lands in tail, except where the estate tail was limited to such man and the heirs of his body, for in that case the lands can only descend to those who are heirs of the body. In all cases where several females take one inheritance by descent, they are called parceners; and all lands or tenements, including a rent charge, may descend in this manner. If there be a title of dignity descendible to heirs of the body, the lands and tenements belonging to it may descend to parceners; but the dignity itself does not descend, for all the parceners only make one heir, and a title of dignity is not in its nature divisible. The dignity therefore will be in abeyance. [BARON.]

The descent of the crown is an exception to this rule; for if there are several daughters, &c., and no male heir, the crown with all its rights descends to the eldest female. In the case of the high constableship of England, if there were parceners, the office was executed by the husband of the eldest daughter, and, before her marriage, by deputy.

Parceners resemble joint tenants in having a unity of title and one entire freehold; but the unity of title can only be by descent, and there is no survivorship among parceners; if one of them dies, her heir is parcener with the survivor or survivors. Parceners resemble tenants in common, in having each a moiety or several interest in the land which has descended to them. It follows from the nature of this interest, that one parcener may either enfeoff another parcener of her share, or release her share to such parcener. If a parcener aliene her undivided share before partition, the alienee is tenant in common with the other parceners.

Parceners may voluntarily make partition of the land among them; or any one might formerly compel her coparceners to make such division by a writ entitled de partitione faciendâ, which was also applicable to the case of joint tenants and tenants in common. The Court of Chancery in course of time acquired a jurisdiction in these matters, and a bill may be filed in chancery by a parcener, praying for partition, which prayer will be granted on the parcener making out her title. The partition is effected by issuing a commission out of chancery to commissioners, who set out and divide the lands, upon which the parties execute mutual conveyances. When partition is made, the several parceners hold their lands as several and distinct estates. By statute 8 & 9 Vict., c. 106, a deed is made necessary to a partition. It might previously have been effected by a writing not under seal. The general Inclosure Act, 8 & 9 Vict., c. 118, contains a provision by which the Inclosure Commissioners are enabled to effect partitions in a more compendious mode than that of a suit in chancery. (2 Blackst. 'Comm.,' p. 320, Mr. Kerr's ed.)

Coparcenary may exist among males and females. For instance, if a man has two daughters, and one of them dies in his life-time, but leaving a son and daughters, and then the father dies, the son of the deceased daughter will be coparcener with his aunt; for he must trace his descent through his mother, who, if she had survived her father, would not have been his heir, but together with her sister, who did survive the father, would have made his heir.

By a recent Act (3 & 4 Will. IV., c. 27, s. 12) it is declared that when a parcener has been in possession of more than her share of the land, or in the receipt of more than her share of the rent, held in coparcenary, for her own benefit or for the benefit of some other persons than her coparceners, such possession or receipt by her shall not be considered the possession or receipt of her coparceners.

When all the sons take the land equally among them by descent, as in the case of gavelkind lands in Kent, they are parceners by custom.

Coparcenary is not very common at present, lands being generally so settled as to prevent its occurrence. The chief rules as to coparcenary are stated in Comyn's 'Digest,' 'Parcener;' and in Littleton, b. iii., "Of Parceners."

PARCHMENT is the skin of an animal prepared for writing upon. The name is a corruption of the Latin *Pergamena*, from Pergamus, the alleged place of its invention. Parchment is said to have been invented by Eumenes II., king of Pergamus (who reigned B.C. 197–159), in consequence of the prohibition of the export of papyrus from Egypt by Ptolemy Epiphanes; but parchment of at least 1000 years earlier date is in the collections of the British Museum. [PAPYRUS.] The probability is, that some improvement was made in the manufacture at Pergamus. The word Pergamena was not used until several centuries after the death of Eumenes. Tatto, a monk of the 4th century, is, according to Mabillon, the first writer in whose works it is met with. Previous to his time the usual term was *membrana*, which is the word we find in the Greek Testament, 2 Timothy, iv 13.

The ancient parchment must have been exceedingly fine, if we are to believe the story of Cicero's having seen the 'Iliad' written on this material enclosed in a nut-shell; but for this we have only Pliny's authority. ('Hist. Nat.,' vii., c. 21.) The parchment of the 7th to the 10th century was white and good; and at the earliest of these periods it appears to have nearly superseded papyrus, which was brittle and more perishable. A very few books of the 7th century have leaves of parchment and papyrus mixed, that the former costly material might strengthen and support the friable paper. About the 11th century it grew worse. This may possibly have arisen from the circumstance, that writers of this time prepared their own parchment, and that they were probably not so skilful as manufacturers; and a dirty coloured parchment is evidence of a want of antiquity. A curious passage from a sermon of Hildebert, archbishop of Tours, who was born in 1054, is a voucher for this fact. The sermon is on the 'Book of Life,' which he recommends his hearers to obtain. "Do you know what a writer does? He first cleanses his parchment from the grease, and takes off the principal part of the dirt; then he entirely rubs off the hair and fibres with pumice-stone; if he did not do so, the letters written upon it would not be good, nor would they last long. He then rules lines, that the writing may be straight. All these things you ought to do, if you wish to possess the book which I have been displaying to you." (Sermon xv., Paris, 1708, fol.) At this time parchment was a very costly material; we find it mentioned that Gui, count of Nevers, having sent a valuable present of plate to the Chartreux of Paris, the unostentatious monks returned it with a request that he would send them parchment instead. It had long been customary to erase ancient writing from parchment by rubbing it with pumice-stone. When the custom began we do not know; but it had became common in the 9th and 10th centuries. [PALIMPSEST.] But the invention of linen paper came in aid to the uses of parchment; and when its manufacture became cheap, it superseded the more costly article for all purposes except those in which luxury was aimed at or uncommon durability required.

Parchment is ordinarily made of the skin of sheep or lambs. For drums it is often made of goat or wolf skins; the parchment with which church-books are covered is made of pigs' skins. Vellum is a finer, smoother, and whiter sort of parchment, made of the skins of very young calves.

Whatever may be the kind of skin used, the process of manufacturing is the same. When the skin is divested of its hair or wool, it is placed for some time in a lime-pit, and then stretched on a square wooden frame drawn tight by pegs. When in the frame, it is first scraped on the flesh side with a blunt iron, then wetted with a moist rag, covered with pounded chalk, and rubbed well with pumice-stone; after a short pause, these operations are repeated, but without chalk; the skin is then turned and scraped on the hair side once only; the flesh side is scraped once more, and again rubbed over with chalk, which must be brushed off with a piece of lamb-skin retaining the wool. All this is done by the skinner, who allows the skin to dry in the frame, and then cuts it out and sends it to the parchment-maker, who repeats the operations with a sharper tool, using a sack stuffed with flocks to lay the skin upon instead of stretching it in a frame. One of the largest pieces of parchment ever prepared forms part of a drum made by Mr. H. Distin for the Crystal Palace, and first used in June, 1860; it is 7 feet in diameter.

There is a kind of parchment made from refuse fish. The skin and offal being removed, all the rest is mixed with a dilute solution of soda ashes or carbonate of potash, and then with a dilute solution of muriatic acid. The mass is then pulped, washed over sieves to remove the bones, &c., drained or pressed, and saturated with a dilute solution of bichloride of mercury. When washed thoroughly, the pulp is formed into sheets in the same way as paper; and these sheets are finally rolled and pressed to equalise the surface. The sheets may either be used as parchment or may be tanned into a kind of leather.

PARCHMENT, VEGETABLE, is a substance lately brought into notice, as an important addition to the materials for manufactures. It is in fact, paper, but paper so altered as to possess many of the qualities of parchment. Messrs. Mongolfier, of Paris, have a mode of so preparing paper as to convert it into a kind of parchment, applicable, among other purposes, as a substitute for goldbeaters'-skin; but Mr. Gaine's vegetable parchment is a different substance. As described before the Royal Institution, in 1857, it appears to be paper altered in its textural qualities by the action of sulphuric acid. [PAPYRIN.] Very little more is required than dipping a sheet of paper into the acid; but then the strength of the acid must be exactly determined. The peculiar effects of acids and alkalies on paper were known long before—as in Kuhlmann's pyroxylised texture, Pelouze's gun paper, and Mercer's process for fibrous textiles; but Mr. Gaine's success depends mainly on the adoption of one particular strength of sulphuric acid, mixed with half its bulk of water. A sheet of paper being dipped in this liquid, it is almost instantly changed in character. It becomes tough, hard, and fibrous, without any alteration of weight. It gives a writing surface far better than that of animal parchment. It receives oils and varnishes freely. It bears rubbing better than any kind of paper, and almost as well as sheepskin. It will serve as a substitute for vellum in bookbinding; as a material for policies, certificates, &c.; as a strong paper for school-books: and as covering for jars and bottles of various kinds. Ordinary paper, even after being printed on, can be converted into this vegetable parchment. The substance is so strong, that a ring seven-eighths of an inch in width, and weighing only 28 grains, is said to bear a suspended weight of 92 lbs.

Soon after Mr. Gaine's process became known, and commercially introduced by Messrs. De la Rue, Mr. W. Crookes made experiments to determine its possible or practicable relation to photography. He passed slips of paper-photographs through acid of the required strength, and found that the colours and tints, even in the delicate half-tones, remained intact; that the uniform contraction of the paper added materially to the sharpness of the picture; that the paper became much stronger than before; that it would bear rough handling immediately, without tearing; that the non-albumenised photographs acquired a peculiar glossy appearance, giving a rich finish without glare; and that the picture might be washed with soap and water, and rubbed with a cloth, without injury.

Professor Muschamp, of Wurtemberg, has devised a mode of making paper waterproof, without, however, giving it those qualities which belong to vegetable parchment. He dissolves 24 ozs. of alum and 4 ozs. of white soap in 2 lbs. of water; also, 2 ozs. of gum arabic, and 6 ozs. of glue, in 2 lbs. of water; the two solutions are mixed, and the sheets of paper dipped into the mixture while warm. The sheets are hung up till dry, and sometimes also passed between rollers. The paper thus prepared is intended for packages exposed to the weather.

PARCLOSE, or **PERCLOSE**, an enclosure; in Gothic architecture the screen or railing which encloses anything, or separates it from the main body of the church. Thus the screen or railing which divides the choir from the nave; shuts off a mortuary chapel; or surrounds a tomb, is termed a parclose.

PARDON. According to the laws of most countries, a power of pardoning, or remitting the penal consequences of a conviction for crimes before the judicial tribunals, is vested in the chief magistrate of the state. The utility of such a power has been doubted by judicial writers, upon the ground that it supposes an imperfect system of criminal law, and that every instance of its exercise is the proclamation of an error either in the law itself or in the administration of justice. (Beccaria, chap. 46.) There is no doubt that the nearer a penal system approaches to perfection, the fewer will be the occasions for resorting to extrajudicial remissions of the execution of the law: but considering the numerous causes of erroneous decision, arising not only from the imperfection of laws themselves, but from the infinite sources of error in the instruments and means by which they are administered, it seems to be desirable that some power should exist which may by timely interference prevent the occurrence of irremediable wrong in cases where the error cannot be corrected by any appellate tribunal. At the same time it is evident that such a power should be circumscribed and defined, as far as its nature will admit, and exercised with the utmost caution. By the law of England, besides pardons by act of parliament, the power of granting pardons for crimes is exclusively vested in the sovereign as a branch of the prerogative. [Prerogative.]

Formerly, Counts Palatine, Lords Marchers, and others who possessed *jura regalia*, had authority to pardon crimes; but by the stat. 27 Henry VIII., c. 24, this power was entirely abolished, and the sole right of remitting the sentence of the laws was permanently vested in the crown. The power of pardoning is applicable in all cases in which the crown is either concerned in interest or prosecutes for the public; the only exception being that contained in the Habeas Corpus Act (31 Car. II., c. 2, s. 12), by which persons convicted of signing commitments of British subjects to foreign prisons, are declared to incur the penalties of a *præmunire* and to be "incapable of any pardon from the crown."

The crown has, moreover, no power to pardon any offence in the prosecution of which a subject has a legal interest, or, as Bracton expresses it, "non potest rex gratiam facere cum injuriâ et damno aliorum" (lib. iii., p. 132). Thus in appeals of death, robbery, or rape, the king could not pardon the defendant, "because," says Sir Edward Coke, "it is the suit of the party to have revenge by death" (3 'Inst.' 237). Upon the same principle, where an attaint was brought against a jury who had delivered a false verdict, and the party in whose favour it had been given was joined in the attaint, the king might pardon the *jury*, if convicted, because they were merely subject to an exemplary punishment; but he could not pardon the *party*, because the latter was liable to make restitution to the plaintiff who prosecuted the attaint. So also in informations upon penal statutes, where the penalty or any part of it goes to the informer, or the party grieved, the crown cannot pardon the offender. Formerly, the crown appears to have exercised without restriction the power of pardoning offenders impeached by the Commons in parliament; but the lawfulness of the exercise of this power during the pendency of the proceedings was questioned by the House of Commons on the impeachment of the Earl of Danby in the reign of Charles II. (Howell's 'State Trials,' vol. ii., p. 724); and it was afterwards enacted, by the Act of Settlement, "that no pardon under the great seal of England shall be *pleadable* to an impeachment by the Commons in Parliament." This statute however does not affect the power of the crown to pardon the offender *after* he has been found guilty upon the impeachment, and the proceedings are determined.

A pardon from the crown to be effectual must apply in express terms to the particular offences intended to be pardoned; and no grant of a commission or protection by the king can amount by implication to a pardon of any offence previously committed.

A pardon may be either absolute or subject to any condition which the crown may think proper to annex to it; and in the latter case, the validity of the pardon will depend upon the performance of the condition. Until the recent improvements in the criminal law of England, almost all felonies were nominally capital; and in the numerous cases where it was not intended that the sentence of death should be executed, the criminal obtained a pardon upon condition of his submitting to transportation or some other punishment. At the present day, where the crown interferes to mitigate or commute a sentence, the mode by which it is effected is by granting a conditional pardon.

It was formerly necessary that a pardon should be under the great seal; but by stat. 7 & 8 Geo. IV., c. 28, s. 13, it is now sufficient, if under the sign manual, and countersigned by one of the secretaries of state.

The effect of a pardon is not merely to prevent the infliction of the punishment denounced by the sentence upon the offender, but to give him a new capacity, credit, and character. A man attainted of felony ceases to be *probus et legalis homo*, and can neither bring an action for damages nor be a witness or a juror in any legal proceeding; but upon receiving a pardon, all these legal disabilities are removed. In this respect a pardon by the law of England differs from the abolitio of the Roman law, to which in other points it bears a near resemblance. According to the latter, "Indulgentia, quos liberat, notat; nec infamiam criminis tollit, sed pœnæ gratiam facit." ('Cod.' lib. ix., tit. 43.) By the English law a distinction is made as to the effect of a pardon where the incapacity is part of the legal sentence, and not merely a consequence of attainder, as in the case of perjury under the statute 5 Elizabeth, c. 9; where the incapacity or infamy is part of a statutory sentence, a pardon from the crown has been held not to restore the party, and in such a case nothing less than an act of parliament will have that effect. Some doubt has been expressed, and the point has not yet received a judicial determination, whether a pardon will fully restore a person convicted of a crime, such as perjury, which is considered infamous at the common law. This subject is elaborately discussed, and all the authorities carefully examined in Mr. Hargrave's 'Argument on the Effect of the King's Pardon of Perjury.'

(Hargrave's *Juridical Arguments*, vol. ii., p. 221.)

PARELLIC ACID ($C_{13}H_{9}O_{8}$?), *Parellin*. One of the substances produced in the various dyeing lichens of commerce. It is found in company with lecanoric acid. [Lichens, *Colouring matters of.*]

PARELLIN. [Parellic Acid.]

PARENT AND CHILD. This relation arises only from a legal marriage. The relation between parents and their illegitimate children is considered in the article Bastard.

Parents are bound to maintain their legitimate children who are unable to maintain themselves owing to infancy or inability to work. This obligation extends to father and mother, grandfather and grandmother, if they are able to perform it (43 Eliz., c. 2; 5 Geo. I., c. 8). But such persons are only bound to furnish the children with the necessaries of life; and the penalty incurred in case of refusal is only 20s. per month. A husband is also, by 4 & 5 Will. IV., c. 76, liable to maintain the children of his wife, born before marriage, whether they are legitimate or not, until they are of the age of sixteen, or until the death of his wife. If a parent deserts his children, the churchwardens and overseers may seize his goods and chattels, and receive his rents, to the amount mentioned in the justices' warrant, which must be obtained before such seizure is made.

Formerly, if a Popish parent refused to allow his Protestant child a suitable maintenance, with the view of compelling him to come over to the Roman Catholic religion, the lord chancellor might enforce from the parent a proper allowance (11 & 12 Will. III., c. 4); and so if Jewish parents refused to allow their Protestant children a maintenance suitable to the parent's fortune and the age and education of the children, the lord chancellor might make such order as he thought proper (1 Anne, st. i. c. 30). Both statutes were repealed by 9 & 10 Vict., c. 59.

Parents are not bound to make any provision for their children after their death. Every man, and every woman who is capable of disposing of her property by will, may dispose of it as they please; except a freeman of London, who is under some limitations as to the power of disposing of his personalty by will, which limitations are in favour of his wife and children. A parent or child may aid each other in a law suit, without being guilty of maintenance. [Maintenance.]

Parents are not legally bound to give any education to their children, nor are they under any restrictions as to the kind of education they may give. Certain penalties might formerly be imposed (1 Jac. I., c. 4; 3 Jac. I., c. 5) on a person who sent a child under his government beyond seas, either to prevent his good education in England or for the purpose of placing him in a Popish college, or being instructed in the Popish religion. The statute 3 Car. I., c. 2, extended these penalties, and added certain disabilities. It seems that it was intended to repeal these penal and disabling statutes by the 31 Geo. III., c. 32, in favour of any Roman Catholic who took the oath therein prescribed. They are now repealed by 2 & 3 Will. IV. c. 115.

The power of a parent over his childen continues until the age of twenty-one, when they are emancipated; and if a parent die leaving a child under age, he may appoint a guardian to such child till the age of twenty-one. A mother has no power over her children.

A child under age may acquire property by gift; and if a father is the trustee of his child's estate, he must account to the child when he comes of age, like any other trustee. So long as a child who is under age lives with and is supported by the father, the father is entitled to receive the reward of the child's labour. When a child has a fortune of his own, and the father is not able to maintain him suitably to such fortune, a court of equity will allow the father a competent sum for maintenance out of the child's estate; but a father is not entitled to any such allowance in respect of costs incurred by him for his child's maintenance before he obtains such order of court for maintenance.

A parent may maintain an action for the seduction of a daughter on the ground of loss of her services, if there is evidence of her acting in the capacity of servant, or living with the parent in such a manner that the parent had a right to her services. This action has been maintained by a father in the case of his daughter, a married woman above age, living separate from her husband, and with the father; and by an aunt for the seduction of her niece living with her, to whom she stood in the relation of parent. The foundation of the right to maintain such an action is the loss of the services to which the parent is entitled.

A father is legally entitled to the care and custody of his children, but he may be deprived of the care of them by the court of chancery, if his conduct is such as, in the opinion of the court, endangers the morals of the children. Percy Bysshe Shelley was, among other things, restrained by an order of the court of chancery from taking possession of the persons of his infant children, on the ground of his professing irreligious and immoral principles and acting on them. W. P. T. L. Wellesley was also restrained by a like order from removing his children from the care and custody of their aunts, on the ground of his immoral conduct, and directions were given by the court for the custody and education of the children. But, except in such cases as these, the children cannot be taken from the care of the father and given into the custody of the mother or any other person.

Under Talfourd's act (2 & 3 Vict., c. 54) a mother may obtain access to her child which is in the sole custody of the father, or of any person by his authority, or of any guardian after the death of the father, subject to such regulations as the court of chancery may think convenient and just; and if such child shall be within the age of seven years, the court may order the child to be delivered into the custody of the mother until the child attains the age of seven years. But no mother is to have the benefit of the act against whom adultery has been established by judgment in an action at law, or by the sentence of an ecclesiastical court.

A child who is under the parental power owes obedience to his parent, which the parent may enforce by his superior strength, provided he uses it with moderation. He may beat his child and restrain his liberty, but not in such a way as to injure his health. A child is legally bound to maintain his indigent father and grandfather, mother and grandmother, if he is able; the penalty in case of refusal is 20*s.* per month.

The paternal power (patria potestas) among the Romans was a peculiar feature in their institutions. It was founded on a legal marriage, or on a legal adoption: the children of such marriage and such adopted children were in the power of the father; the mother had no power over them. It followed from the principle of the patria potestas, which involved a right of property, that the children of a son, not emancipated, were also in the power of their grandfather. By the death of the grandfather the son became *sui juris*, and his children and grandchildren fell into his power. This patria potestas could be dissolved by EMANCIPATION. Originally the father's power was absolute over the child, who had no independent political existence, at least as a member of his father's family. He was a Roman citizen, but at home he was subject to the domestic tribunal. Within the family the father had a power of life and death, and could sell the son as a res mancipi, either by way of punishment, or by way of dissolving the family connection. [EMANCIPATION.] The father also originally possessed the jus noxae dandi with respect to his son as well as a slave, a power which was a consequence of the principle of the father being answerable for the delicts of his son, and continued so long as that principle was in full vigour. The son who was in the power of his father could acquire no property for himself; all his acquisitions, like those of a slave, belonged to his father; but at the death of the father they might become his own property, a circumstance which distinguished the acquisitions of a son from those of a slave. The father could marry his children, divorce them, give them in adoption, and emancipate them at pleasure.

The strict notion of the patria potestas lies at the foundation of the Roman polity. Like other institutions, however, which in the early history of a state form its essential elements, the strict character of the patria potestas became gradually relaxed and greatly changed. The history of such changes is part of the history of Rome.

The patria potestas might be dissolved in other ways besides those mentioned. If a father or son lost his citizenship, the relation between them ceased, for this relationship could only exist between Roman citizens. If father or son was made a prisoner by an enemy, the relation was in abeyance (in suspenso), but was not extinct. If the son attained certain high offices in the state, either civil or religious, the patria potestas was thereupon dissolved.

(Gaius, i. 55, 97, 127, &c.; Marezoll, *Lehrbuch der Instit. des Röm. Rechtes*, 1839; Savigny, *System des heutigen Röm. Rechts*, 1840.)

PARGETING, or PARGE-WORK, the old English term for plasterwork in building. It is now chiefly applied to the ornamental plasterwork, mostly of patterns moulded in relief, of which characteristic examples are seen on the fronts of houses of the reigns of Elizabeth and James I., some of which are very picturesque. By workmen the term is used in the present day for the plastering of the sides of chimney-places and other coarse work.

PARHE'LION (παρὰ, by the side of, ἥλιος, the sun), a name given to the mock suns, as they have been called, which sometimes appear near the sun; being, as is supposed, images of the latter formed by reflection from a cloud.

PARIAN CHRONICLE is the name given to a block of marble preserved at Oxford, which contained in its perfect state a chronological account of the principal events in Greek history during a period of 1318 years, beginning with Cecrops, B.C. 1582, and ending with the archonship of Diognetus, at Athens, B.C. 264. The chronicle of the last ninety years was however lost, so that the part which now remains ends at the archonship of Diotimus, B.C. 354. This chronicle was purchased at Smyrna, together with several other relics of antiquity, by Mr. William Petty, who was employed by the Earl of Arundel, in the year 1624, for the purpose of making collections for him of ancient works of art in Greece, Asia Minor, and the islands of the Archipelago. Gassendi states in his 'Life of Peiresc' (lib. iv., ed. of 1629), who was counsellor in the parliament of Provence, and a munificent patron of arts and learning, that the Parian Chronicle was first discovered by means of Peiresc, and was purchased for him by one Sampson, his agent at Smyrna, for fifty pieces of gold, but that when it was ready to be sent on board, Sampson was thrown into prison, and that the Chronicle was afterwards purchased for Lord Arundel, by Mr. Petty, at a much higher price. Dr. Hales, in his 'Analysis of Chronology' (vol. i. p. 103, 8vo. edition), brings forward several reasons to show the improbability of this account; but however this may be, the Chronicle reached London in 1627, and was examined, at the suggestion of Sir Robert Cotton, with great care by the learned Selden, in conjunction with Patrick Young, librarian to James I. and Charles I., and Richard James, Fellow of Corpus Christi College, Oxford. "Many of the characters," says Selden, "were entirely obliterated, and many nearly so; nevertheless, by the assistance of glasses, and the critical sagacity of my very kind friend Patrick Young, after a great many repeated trials, I have restored them as well as I could." The Chronicle was published by Selden, together with other inscriptions which were brought to England by Mr. Petty in the following year (1628), under the title of 'Marmora Arundelliana.'

During the civil war in the reign of Charles I., the Earl of Arundel removed to Antwerp, and many of the marbles, which were deposited in the gardens of Arundel House, were defaced and broken, or used to repair the house. The latter was the fate of the Parian Chronicle; the upper part of it, containing at least half the inscription, is said to have been worked up in repairing a chimney at Arundel House; but fortunately a copy of it was preserved in Selden's work.

In 1667 the Hon. Henry Howard, grandson of the Earl of Arundel who obtained the Chronicle from Greece, presented it to the University of Oxford, where it is preserved, together with other antiquities collected by the Earl of Arundel, in a room adjoining to the public schools, called the Museum Arundelianum. The Chronicle was published again in Prideaux's 'Marmora Oxoniensia,' fol. 1676, which was reprinted in 1732, under the care of Michael Maittaire, and again in 1791, Oxford, under the care of W. Roberts. In Chandler's 'Marmora Oxoniensia,' which was published in 1763, great pains were bestowed upon the Parian Chronicle, and many parts in which the inscription was defaced were supplied by conjectures, which are frequently very ingenious and probable. It has also been published, with an English translation, in the works of Robertson, Hewlett, and Hales, which are mentioned in the course of this article.

The authenticity and antiquity of this Chronicle was never called in question till the latter end of the last century, when a work was published by the Rev. J. Robertson under the title of 'The Parian Chronicle, or the Chronicle of the Arundelian Marbles, with a Dissertation concerning its Authenticity,' London, 1788, in which it is maintained to be a fabrication of modern times. The principal objections brought forward by Robertson are:—1. That the characters have no certain or unequivocal marks of antiquity. 2. It is not probable that the Chronicle was engraved for private use. 3. It does not appear to have been engraved by public authority. 4. The Greek and Roman writers for a long time after the date of this Chronicle complain that they had no chronological account of the affairs of ancient Greece. 5. This Chronicle is not once mentioned by any writer of antiquity. 6. Some of the facts seem to be taken from authors of a later date. 7. Parachronisms appear in some of the epochas, which we can hardly suppose a Greek chronologer in the 129th Olympiad would be likely to commit, &c.

The objections of Robertson were replied to by Mr. Hewlett, in a work entitled 'A Vindication of the Authenticity of the Parian Chronicle,' London, 1789: by Mr. Gough, in the ninth volume of the 'Archæologia;' and by Porson, in the 'Monthly Review,' in 1789. His objections have been more recently noticed in the first volume of Hales's 'Chronology;' and the whole subject has been investigated with great accuracy by Böckh, in the second volume of his 'Corpus Inscriptionum.' The authenticity of the Chronicle has been also vindicated by Wagner, Gött., 1790, 8vo. The result of these inquiries can leave little doubt respecting the authenticity and antiquity of the Chronicle; and the subsequent silence of classical writers respecting it, which is perhaps the strongest argument against its antiquity, may be accounted for, as Dr. Hales has remarked, by the retired and insular situation of Paros. It is written in pure and classical Greek; the characters bear several marks of antiquity; and none of the passages adduced by Robertson to prove that parts of it were taken from writers of a later date are sufficient to establish the fact.

The marble on which the Chronicle was engraved was five inches thick, and measured, when Selden viewed it, 3 feet 7 inches by 2 feet 7 inches; but one corner had been broken off. It contained at that time 93 lines, reckoning the imperfect ones, and might originally perhaps have contained a hundred. Upon an average the lines consist of 130 letters, all capitals, in close continuation, and unbroken into words. The events which it records are not so much those which relate to the history of the different states of Greece, but rather such as serve to illustrate the history of the civilisation and literature of

Greece. Thus we do not find one event in the Peloponnesian war either mentioned or alluded to, but we have an account of the establishment of the principal religious festivals, of the introduction of the different kinds of music into those festivals, of the origin of tragedy and comedy, and of the time in which the most eminent poets and philosophers lived.

For an examination of the dates which are assigned to the different events it records, the reader is referred to the first volume of Hales's 'Analysis of Chronology.'

PARIDIN ($C_{12}H_{10}O_6$?). A crystalline, colourless, organic substance found in the leaves of the *Paris quadrifolia*. It is coloured red by concentrated phosphoric or sulphuric acid.

PARIETIN. A name first given to a substance extracted from *Parmelia parietina*, but which has now been proved to be identical with usnic acid. [USNIC ACID.]

PARIGLIN. [SMILACIN.]

PARING AND BURNING. This operation consists in cutting a thin slice from the surface of land which is overgrown with grass, heath, fern, or any other plants which form a sward by the matting together of their roots. The sods are allowed to dry in the sun to a certain degree, after which they are arranged in heaps, and burnt slowly, without flame or violent heat. The result is a mixture of burnt earth, charred vegetable fibre, and the ashes of that part which is entirely consumed.

The object of this operation is twofold: first, to kill insects and destroy useless or noxious weeds completely; and secondly, to obtain a powerful manure, impregnated with alkaline salts and carbonaceous matter, which experience has shown to be a very powerful promoter of vegetation.

The instruments by which this is effected are, either a common plough with a very flat share, which may be used when the surface is very level without being encumbered with stones or large roots, as in low moist meadows, or in most other cases a paring-iron used by hand. Instead of the common plough, Snowden's or Woofe's paring plough (Hancock, Gloucester) may be used. It is a very effective tool—self-cleaning in its operation—and capable of cutting a thinner slice than can be separated by the common plough. The hand-parer is a most cumbrous tool, and in its use the power of the workman is most wastefully exerted. The crossbar of the instrument is held with both hands; and the upper parts of the thighs, being protected by two small slips of board, push the instrument into the ground, so as to cut a slice of the required thickness, which is then turned over by moving the cross-handle. The labour is severe, and a good workman can scarcely pare more than one-sixth of an acre in a day. The price of this work is from 15*s.* to 25*s.* per acre, according to the price of labour. The drying, burning, and spreading of the ashes are contracted for at from 10*s.* to 15*s.* more: thus the whole cost is from 25*s.* to 2*l.* per acre. In France it is done by a *cob*, which is like a shipwright's adze, and the operation is called *écobuer*.

Paring and burning the surface is an almost invariable preliminary in the converting of waste lands to tillage; and where these lands are in a state of nature, overrun with wild plants which cannot be easily brought to decay by simply burying them in the ground, burning is the readiest and most effectual mode of destroying them. In this case the practice is universally recommended and approved of.

But it is not only in the reclaiming of waste lands, and bringing them into cultivation, that paring and burning the surface is practised. The fertility produced by the ashes, which is proved by the luxuriance of the vegetation in the first crop, has induced many to repeat this process so often, as materially to exhaust the soil, and induce partial sterility. Hence the practice has been recommended on the one hand, and strongly reprobated on the other.

When we come to apply to the subject the test of experience, and reason correctly on the facts which are presented to us by the abettors of the practice and its adversaries, we shall find that the advantages and disadvantages arise chiefly from the circumstances under which the operation is carried on. But it may be necessary to an impartial examination of the subject, to inquire into the changes produced on the substances subjected to the process of burning, when it is done with due precautions.

In burning vegetable matter in an open fire, the whole of the carbon is converted into carbonic acid and flies off, leaving only some light ashes containing the earthy matter and the salts which the fire could not dissipate. These are no doubt very powerful agents in promoting vegetation, when they are added to any soil: but they are obtained at a very great expense of vegetable matter, which by its decomposition in the earth, might also have afforded food for vegetation. If the earth which is burnt with the sods is of a cold clayey nature, the fire will change it into a kind of sand, or brick dust, which is insoluble in water, and corrects the too great tenacity of clays, by converting them more or less into loams. This is so well known, that clay is often dug out of the subsoil to be partially burnt. But in addition to the many mechanical effects of heat on clay, there are certain chemical results of great advantage to fertility. When not burned to excess the alkaline ingredients of clays become more soluble when they are exposed to heat, and no doubt some of the beneficial effects of clay burning are due to the greater quantity of soluble alkaline matter which is then made available: and on stiff clay soils therefore there is a double advantage in paring and burning, that of the vegetable ashes and of the burnt clay.

Burning clay soils is in fact something analogous to liming. Lime dissolves the vegetable matter and sets free the alkalies, and it enables the detached elements to enter into new combinations; but if no new vegetable matter be added to restore what is exhausted by vegetation, liming, as well as paring and burning, is detrimental in the end. Many experienced farmers pare and burn the soil on the edges of their ditches and on the banks on which the hedges grow, because they thereby exterminate many rank weeds; and the burnt earth mixed with farm-yard dung makes an admirable compost. Here the burnt earth acts as an absorbent, and no doubt attracts many of the volatile parts of the manure, which are produced by the decomposition of animal and vegetable matter in it. Paring and burning therefore should be joined to manuring, if a powerful and immediate effect is desired without exhausting the soil; and in this case we do not hesitate to recommend it on all cold clay soils where rank weeds are apt to spring up, and coarse grasses take the place of the better sorts which have been sown. The proper time to pare and burn is evidently after the land has lain in grass for several years, and is broken up for tillage. The surface should be pared thin; about two inches is the extreme thickness allowable for the sod if the soil is very stiff and poor, and as thin as possible in a better soil. The sods should be moderately dried, and then arranged into small heaps with a hollow in the middle to hold heath or bushes to kindle the fire. When it has fairly established itself, all the apertures should be carefully closed. Wherever any fire breaks out, a fresh sod should be immediately put over it; a heap containing a small cart-load of sods should be smouldering for several days without going out, even if it rains hard. If the fire is too brisk, the earth will form hard lumps, and even vitrify; but otherwise it comes out in the form of a fine powder, in which evident marks of charcoal appear. If this is of a fine red colour, it is a good sign; for the iron in the earth has been converted into a peroxide, which is perfectly innocent in its effects on vegetation, whereas all the saline impregnations of iron are more or less hurtful. It is better to burn the sods in large than in small heaps; for the more the fire is smothered, the better the ashes.

So great a quantity of ashes is sometimes produced as to admit of a portion being carried off on grass-land, or used to manure another field for turnips. As this is evidently robbing the field where the operation has been carried on, an equivalent quantity of manure should be brought in exchange. Perhaps the most advantageous mode of using the ashes is to spread them in the drills where the turnip-seed is to be sown, after a portion of dung has been buried under them. In this manner the ashes from one acre of land pared and burnt, together with ten or twelve cart-loads of good yard dung, and a half dressing of superphosphate of lime, will manure two acres, and all the manure of one acre, in the ordinary mode of raising turnips on ridges, will be saved. If the ashes will produce as good turnips with half the usual quantity of dung, the expense of paring and burning is amply repaid. But experience proves that the earth and ashes almost ensure a good crop of turnips in many poor stiff soils in which they would probably not have succeeded if sown in the common course of cultivation without bones or ashes.

When a considerable extent of poor land is brought into cultivation, and there is no sufficient supply of manure at hand, paring and burning a portion of the land every year, by which a crop of turnips is obtained, is a most effectual means of improvement. Lime may be used at the same time with the ashes, and will increase their effect, provided some vegetable undecayed matter remains in the soil after paring; but lime will tend to exhaust this; and if, in consequence of liming, a few good crops of corn are obtained at first, the soil will be so exhausted as to be of little value afterwards. This is the abuse of the practice, which has caused it to come into disrepute. It would be a great waste to burn the surface of a rich piece of grass-land where the plants growing in it are tender and succulent, and would readily rot on being ploughed under; in such case a moderate application of lime would have a much better effect. This kind of land will produce good crops without any manure, and continue fertile for many years if judiciously cultivated. To pare and burn rich land is wasteful, and can never be recommended. It is only on poor land which has not strength to produce a crop, and of which the texture requires to be improved and its powers stimulated, that paring and burning is advantageous; on poor thin chalky soils which have been laid down with sainfoin, of which the roots and stems are grown coarse and hard, so as not readily to rot in the ground, the operation is proper and advantageous. The turnips produced by the ashes, with or without the assistance of dung, must be fed off by sheep folded on the land, whose dung and urine will enrich it, and their tread consolidate it. By this mode of proceeding great advantages are obtained from paring and burning, and the land, so far from being deteriorated, will be improved.

Many landlords rigidly forbid their tenants to pare and burn any part of their land, from an idea that the heart of it is destroyed by the burning. But in the hands of an intelligent tenant the practice is perfectly safe and even beneficial, for he knows it to be his interest to apply a certain quantity of dung, either at the same time that the land is thus treated, or for the next crop, and where under ordinary farming there is no sowing of corn crops except after turnips, clover, or some other green crop consumed on the farm, there could be little danger of any detriment to the land, even if it were pared and burnt once in every ten or twelve years, provided it were judiciously treated in the intervals. The farmer would be benefited in many situations, and the practice would tend to keep up the value of the farms.

In Devonshire, where the land has been pared and burnt from time immemorial, even where the soil is rich, the practice has been often resorted to without any judgment. Provided a crop of corn or potatoes was obtained at little cost, the consequences to the future state of the land were not heeded; and landlords, seeing their farms impoverished, put a stop to the practice. Thus many useful modes of cultivation have been reprobated from the abuse of them, which, properly applied, would have been advantageous to all parties. There is no maxim more true than this: that whatever injures the landlord, injures the farmer who is not desirous of removing, and *vice versâ*; and all positive restrictions on cultivation, however necessary when there is a fear of dishonest conduct, diminish the value of a farm and lessen the rent which can be fairly afforded for it. Ignorance is often a greater destroyer of the interest of both landlord and tenant than wilful dishonesty; and the spreading of useful information amongst tenants, so that they may see their own advantage, is the surest means of improving landed property. Many tracts of waste land might be brought into cultivation by means of paring and burning, which without it would never repay the labour required. Where the soil is inclined to peat, this operation and abundant liming are the indispensable preliminaries of cultivation. The ashes and the lime will produce vegetation and food for animals. These will produce dung to supply what the vegetation abstracts, and to assist also in the further decomposition of the peaty matter, converting it into vegetable mould.

The first crop after paring and burning, as was observed before, should, if possible, be turnips, and these should be consumed on the spot; but there are exceptions to the rule. The soil may be a stiff clay of a considerable degree of natural fertility, only encumbered with rank weeds and grasses. In this case the surface is burnt to destroy these, and a crop of corn may safely be taken after the paring and burning, the land coming into a regular alternate rotation after it. For example, the next crop may be beans or tares, with a good proportion of dung; or clover may be sown with the first crop, if the ground appears fit for it. The effect of the ashes will be readily perceived in the luxuriance of the clover. Such land may be afterwards cultivated, according to its nature and quality, with the rest of the farm; or laid down to grass after a course of cleansing and ameliorating crops. Thus old wet meadows, after having been well underdrained, may be greatly improved, and either converted into arable fields or laid down again with choice grasses.

Old rough pastures have often been greatly improved by a very thin paring and burning, so as not to destroy all the roots of the grass. When the ashes are spread over the pared surface, some good grass-seeds are sown with them. The whole is well harrowed or scarified and rolled, and the grass which will spring up after this will be greatly improved, and will fully repay the expense of this simple mode of renovating it. This is the cheapest mode of improving coarse pastures that we know, without breaking them up.

The partial paring and burning of the headlands of fields, for the purpose of mixing the ashes and burnt earth with dung in a compost, is a most excellent practice, and often superior to that of using the sods only, without burning them. These sods contain innumerable seeds of weeds, and eggs or maggots of insects, which are not destroyed by the fermentation of the heap, but on the contrary, are brought to life. The loss of a portion of vegetable matter in the burning is amply compensated by the destruction of these enemies of the future crops.

It now only remains to take notice of the soils and situations where paring and burning cannot be recommended. Wherever the soil is very loose from a great proportion of silicious sand in its composition, and is held together chiefly by the slender roots which run through it, the burning would destroy the whole of the vegetable matter; and the residue would be a mere barren silicious sand, much worse and more porous than it was when held together by the roots. The only way to bring such soils into cultivation is to put clay or marl on them, and to force vegetation by means of liquid and other manures, consolidating them by every means applicable, so that they may retain moisture, and that the manure may not be washed through by the rains. Such soils may be improved, but they are the most ungrateful of any; and it is only necessity and indefatigable industry which can make them produce any crops.

On the whole, the operation of paring and burning, when judiciously applied and properly performed, is a most excellent and cheap improvement of dry soils, and it will never diminish their fertility, if they are properly cultivated and manured, and a judicious succession of crops is adopted; but on the contrary it will improve their quality and texture, and make them more productive.

PARIS RED. [COLOURING MATTERS.]

PARIS YELLOW. [COLOURING MATTERS.]

PARISH. This word is probably derived into the English language from the French *paroisse*, and the Latin *parochia* or *parœcia*, and ultimately from the Greek *paroikia* (παροικία). At the present day it denotes a circumscribed territory, varying in extent and population, but annexed to a single church, whose incumbent or minister is entitled by law to the tithes and spiritual offerings within the territory. In the early ages of Christianity the term appears to have been used in some parts of Europe to signify the district or diocese of a bishop, as distinguished from the 'provincia' of the archbishop or metropolitan. (Du Cange, 'Gloss.,' ad verb. 'Parochia;' Selden's 'History of Tithes,' chap. vi., sect. 3.) These large ecclesiastical provinces were gradually broken down into subdivisions, for which ministers were appointed, either permanently or occasionally, who were under the rule of the bishop, were paid out of the common treasury of the bishopric, and had no particular interest in the oblations or profits of the church to which their ministry applied. This was the state of things in the primitive times, which probably continued till towards the end of the 3rd century. After that period proprietors of lands began, with the licence of the higher ecclesiastical authorities, to build and endow churches in their own possessions; and in such cases the chaplain or priest was not paid by the bishop, but was permitted to receive for his maintenance and to the particular use of his own church the profits or the proportion of the profits of the lands with which the founder had endowed it, as well as the offerings of such as repaired thither for divine service. This appears to be a probable account of the origin and gradual formation of parochial divisions in almost all countries where Christianity prevailed; and Selden has satisfactorily shown that the history of parishes in England has followed the same course. Soon after the first introduction of Christianity into this country, the heathen temples and other buildings were converted into churches or places of assembly, to which the inhabitants of the surrounding district came to receive religious instruction from the minister, and to exercise the rites of Christian worship. As the members of the new religion increased, a single or occasional minister was insufficient for the purpose; and a bishop, with subordinate priests, began to reside in the immediate neighbourhood of the religious houses, having the charge of districts of various extent, comprehending several towns and villages, and assigned principally with a view to the convenience of the inhabitants in assembling together at the church. Within these districts, or *circuits*, as they were called, which were precisely analogous to the diocesan *parishes* in other parts of Europe, the ministering priests itinerated for the purpose of exercising their *shriving*, but they always resided with the bishop. By degrees other churches were built to meet the demands for public worship, but still at first wholly depending upon the mother-church, and supplied by the bishop from his family of clergy resident at the bishopric with ministers or curates, who were supported by the common stock of the diocese. For the fund or endowment in each of these districts was common; and whatsoever was received from tithes or the offerings of devotees at the different altars, or by any other means given for religious uses, was made into a general treasure or stock for the ecclesiastical purposes of the whole diocese; and was applied by the bishop in the first place to the maintenance of himself and the college of priests resident with him at the church, and afterwards for distribution in alms among the poor and for the reparation of churches.

This community of residence and interest between the bishop and his attending clergy, who are often termed in the chronicles of those days *episcopi clerus*, constituted the notion of cathedral churches and monasteries in their simplest form. How long this state of things continued does not precisely appear, though Selden expresses an opinion that it was in existence as late as the 8th century. ('History of Tithes,' chap. ix., sect. 2.) It has indeed been asserted by Camden ('Britannia,' p. 160), and was formerly the commonly received opinion, that Honorius, the first archbishop of Canterbury after Augustine, divided his province into parishes about the year 630; but Selden proves satisfactorily that Honorius could not have made a parochial division in the sense in which we now understand the term; and that, if made at all, it must have been such a distribution into districts, then called parishes, as is above described, and which was so far from originating with Honorius, that it must have been nearly as ancient as bishoprics.

It seems most probable that the creation of parishes in England was not a simultaneous act, but was the gradual result of circumstances, and was not fully effected till near the time of the Conquest. (Hallam's 'Middle Ages,' vol. ii., c. 7, pt 1.) As Christianity became the universal religion, and as population increased, the means of divine worship supplied by the bishoprics and monasteries became inadequate to the wants of society, and lords of manors began to build upon their own demesnes churches and oratories for the religious purposes of their families and tenants. Each founder assigned a definite district, within which the functions of the minister officiating at his church were to be exercised, and expressly limited the burden as well as the advantages of his ministry to the inhabitants of that district. As these acts of piety tended to the advancement of religion, and were in aid of the common treasury of the diocese, they were encouraged by the bishops, who readily consecrated the places of worship so established, and consented that the minister or incumbent should be resident at his church, and receive for his maintenance, and for the use of that particular church, the tithes and offerings of the inhabitants, as well as any endowment or salary which the founder annexed to it. This endowment or salary usually consisted of a glebe, or a portion of land appropriated to that purpose, which was indeed the only means of providing for the maintenance of the incumbent at a time when almost all the wants of life were supplied from the immediate produce of the earth, and, together with the right of receiving the other ecclesiastical profits which arose within the territory limited by the founder, became the settled revenue of the church, and annexed to it in perpetuity. The last concession made to the lay founder was probably the patronage or right of presenting the clerk to the church, which by the primitive constitution, belonged exclusively to the bishop; and when this was obtained, these limited territories differed in no material respect from our modern parishes. Indeed it can scarcely admit of doubt that our parochial divisions arose chiefly from these lay-foundations, the differences in extent being accounted for by the varying limits appointed for them at their origin. Their names were derived from some favourite saint, from the site, or the lordship to which they belonged, or from the mere fancy of the respective founders. Such appears to have been the origin of the lay parishes; and it is reasonable to conclude that as soon as this practice was established, the bishops and religious houses, in the districts or parishes in which they had reserved to themselves the right of presentation, followed the same course by limiting the ecclesiastical profits of each church to the particular incumbent, and restricting the devotions as well as the offerings of the inhabitants to that church only.

The earliest notice of these lay foundations of parishes is by Bede, about the year 700 ('Hist. Eccl.' lib. v., c. 4 and 5). By the end of the 8th century they had become frequent, as clearly appears from the charters of confirmation made to Croyland Abbey, by Bertulph, king of Mercia, in which several churches of lay-foundation are comprehended. In the laws of king Edgar (A.D. 970) there is an express provision that every man shall pay his tithes to the most ancient church or monastery where he hears God's service; "Which I understand not otherwise," says Selden, "than any church or monastery whither usually, in respect of his commorancy or his parish, he repaired: that is, his parish church or monastery." ('History of Tithes,' chap. ix., 1-4.)

Although the origin of parishes generally in England is pretty clearly ascertained, the history of the formation of particular parishes is almost wholly unknown. As these divisions originated in an unlettered period, and were too local and obscure to be recorded in the chronicles or general histories of the times, and for the most part too ancient to be preserved in any episcopal registers now existing, it would be unreasonable to expect any satisfactory evidence of their particular origin; and as a matter of fact, no evidence whatever can be produced on the subject.

However satisfactory this account of the origin of parishes may be with reference to country parishes, it furnishes no explanation of the origin of parishes in towns—a subject which is involved in great obscurity; and indeed the changes which the latter may be shown to have undergone within time of memory seem to point to a different principle of formation.

The country parishes appear to be nearly the same in name and number at the present time as they were at the time of Pope Nicholas's 'Taxation,' compiled in the reign of Edward I. (A.D. 1288); but in some of the large towns the number of parishes has very considerably decreased. Thus, in the city of London there are at present 108 parishes, though at the time of the 'Taxation' the number was 140; in like manner in Norwich the number has been reduced from 70 in the time of Edward I., to 37 at the present day. In other ancient towns, such as Bristol, York, and Exeter, the number does not appear to have materially changed, but the names have been often altered. The particular causes of these variations it would be difficult to trace; but greater changes might reasonably be expected in towns than in the country parishes, in consequence of more frequent fluctuations of wealth and population in the former. Where a decrease has taken place in the number of town parishes in the three last centuries, it is probably to be accounted for by the great reduction since the Reformation in the amount of oblations and what are called *personal* tithes, which in cities were almost the only provision for the parochial clergy.

The size of English parishes varies much in different districts. In the northern counties they are extremely large, forty square miles being no unusual area for a parish; and, generally speaking, parishes in the north are said to average seven or eight times the area of those in the southern counties. The boundaries of parishes in former times appear to have been often ill-defined and uncertain; but since the establishment of a compulsory provision for the poor by means of assessments of the inhabitants of parishes, the limits have in general been ascertained with sufficient precision.

It is not easy to ascertain the exact number of parishes in England and Wales; for although they have been enumerated on several occasions, the number ascertained has usually depended upon the object and purpose of the particular enumeration. Thus in the returns under the Poor Law Commission, a parish is generally considered as a place or district supporting its own poor, and from these returns, in 1854, it appears that the total number of such places is 14,603, and the number is constantly increasing with the increase of population. But in this number are included many subdivisions of parishes, such as the townships in the northern counties, which by stat. 13 & 14 Car. II., c. 12, f. 21, are permitted to maintain their own poor, and also other places which by act of parliament, though not parishes, have the same privilege. Another difficulty, which has probably affected all the enumerations which have hitherto been made, is the large number of doubtful parishes. It is somewhat uncertain at the present day what circumstances constitute a parish church. In the Saxon times, and for some centuries after the Conquest, the characteristics which distinguished a parish church from what were called field churches, oratories, and chapels, were the rights of baptism and sepulture. (Selden, 'History of Tithes,' chap. ix., 4; Degge's 'Parsons' Counsellor,' part i., chap. xii.) But in modern times this line of distinction would include as parish churches almost all chapels-of-ease, and also the churches and parochial chapels erected under the stat. 58 Geo. III., c. 45, "for building additional churches in populous places." The various views entertained of the constituents of a parish will in a great measure account for the different results of the several enumerations which have been made; and this is in fact one of the reasons assigned by Camden for the difference between the number of the parish churches in England and Wales stated to Henry VIII. in 1520, by Cardinal Wolsey, and that stated about a century after to James I., the former being 9407, and the latter 9284. (Camden's 'Britannia,' 161-2.) The number of the parishes mentioned in Pope Nicholas's 'Taxation' above referred to, as nearly as can be ascertained, appears to be between these two accounts. Blackstone says, that the number of parishes in England and Wales had been computed at 10,000. Perhaps the number of parishes in England and Wales (meaning by the term simply a district annexed to a church whose incumbent is by law entitled to tithes in that district) may be taken to be about 11,000.

(See Holland's 'Observations on the Origin of Parishes,' in Hearne's *Discourses*, vol. i. p. 194; and Whitaker's *History of Whalley*, book ii. chap. l.)

PARK. This term, in its legal signification as a privileged enclosure for beasts of the forest and chace, is at the present day nearly obsolete. Under the ancient forest-laws, the franchise of the highest degree was that of a forest which was *nomen generalissimum*, and contained within it the franchises of chace, park, and warren. The only distinction between a chace and a park was, that the latter was enclosed, whereas a chace was always open, and they both differed from a forest, inasmuch as they had no peculiar courts or judicial officers, nor any particular laws, being subject to the general laws of the forest; or as Sir Edward Coke maintains, to the common law exclusive of the forest-laws. (4 'Inst.,' 314.) A chace and a park differed from a forest also in the nature of the wild animals to the protection of which each was applied. The beasts of the forest, or beasts of venery, as they were called, were *tantùm silvestres*, that is, as Manwood explains the phrase ('Forest Laws,' chap. iv., sec. 4), animals such as the hart, hind, hare, boar, and wolf, which "do keep the coverts, and haunt the woods more than the plains." On the other hand, the beasts of chace or park were *tantùm campestres*, that is to say, they haunted the plains more than the woods. According to the strict legal meaning of the term, no subject can set up a park without the grant of the Crown or immemorial prescription, which is presumptive evidence of such a grant. In modern times the term is little known, except in its popular acceptation as an ornamental enclosure for the real or ostensible purpose of keeping fallow deer, interspersed with wood and pasture for their protection and support. (Blackst. 'Comm.' Mr. Kerr's ed. vol. ii.)

PARK OF ARTILLERY. [Artillery Park.]

PARK, ENGINEER, is the term applied to the whole equipment of stores, intrenching tools, &c. belonging to the engineer department in the field, and to the depôt where these are stored, and where the officers and men of this branch of the service are camped. In a siege the engineer park should be as near as possible to the siege works, but covered from the enemy's fire. Natural positions, in hollows and behind hills, affording such protection, may generally be found within 1000 yards or so of the first parallel.

PARKS, PUBLIC. [Arboretum.]

PARLIAMENT, IMPERIAL, the legislature of the United Kingdom of Great Britain and Ireland, consisting of the king or queen [King], the lords spiritual and temporal [Lords, House of], and the knights, citizens, and burgesses [Commons, House of] in parliament assembled.

The word is generally considered to be derived from the French *parler*, to speak. "It was first applied," says Blackstone, "to general assemblies of the states under Louis VII. in France about the middle of the 12th century." The earliest mention of it in the statutes is in the preamble to the statute of Westminster, A.D. 1272.

Origin and Antiquity of Parliament.

The origin of any ancient institution must be difficult to trace, when in the course of time it has undergone great changes; and few subjects have afforded to antiquaries more cause for learned research and ingenious conjecture than the growth of our parliament into the form which it had assumed when authentic records of its existence and constitution are to be found. Great councils of the nation existed in England both under the Saxons and Normans, and appear to have been common amongst all the nations of the north of Europe. They were called by the Saxons *michel-synoth*, or great council; *michel-gemote*, or great meeting; and *wittena-gemote*, meeting of wise men—by the last of which they are now most familiarly known.

The constitution of these councils cannot be known with any certainty, and there has been much controversy on the subject, and especially as to the share of authority enjoyed by the people. Different periods have been assigned for their admittance into the legislature. Coke, Spelman, Camden, and Prynne agree that the commons formed part of the great synods or councils before the Conquest; but how they were summoned, and what degree of power they possessed, is a matter of doubt and obscurity. "The main constitution of parliament, as it now stands," says Blackstone, "was marked out so long ago as the seventeenth year of King John, A.D. 1215, in the great charter granted by that prince, wherein he promises to summon all archbishops, bishops, abbots, earls, and greater barons [BARONS] personally, and all other tenants in chief under the crown by the sheriff and bailiffs, to meet at a certain place, with forty days' notice, to assess aids and scutages when necessary; and this constitution has subsisted, in fact at least, from the year 1266, 49 Hen. III., there being still extant writs of that date, issued by Simon de Montfort, earl of Leicester, to summon knights, citizens, and burgesses to parliament." A statute, also, passed 15 Edw. II (1322), declares that "the matters to be established for the estate of the king and of his heirs, and for the estate of the realm and of the people, should be treated, accorded, and established in parliament, by the king and by the assent of the prelates, earls, and barons, and the commonwealth of the realm, *according as had been before accustomed*." In reference to this statute, Mr. Hallam observes, "that it not only establishes by a legislative declaration the present constitution of parliament, but recognises it as already standing upon a custom of some length of time." (1 'Const. Hist.,' 5.)

CONSTITUENT PARTS OF PARLIAMENT.

These have been treated of in separate articles, and nothing more will be attempted in this place than a brief analysis, which will bring the whole under one view. Of the king (or queen), the first in rank, nothing need be repeated.

The House of Lords is at present composed of—

LORDS SPIRITUAL.

2 archbishops (York and Canterbury)
24 English bishops
4 Irish representative bishops

Total, 30

LORDS TEMPORAL.

3 princes of the blood royal
20 dukes
21 marquesses
111 earls
22 viscounts
213 barons
16 representative peers of Scotland
28 representative peers of Ireland

Total, 461

The number has been greatly augmented from time to time, and there is no limitation of the power of the crown to add to it by further creations. The titles of all temporal peers are now hereditary; since the decision of the House of Lords in 1856 (when by letters patent Baron Wensleydale was created "for and during his natural life"), that neither such letters patent, nor the writ of summons, could enable the person named therein to sit or vote in parliament. The introduction of the representative peers of Scotland and Ireland was effected on the union of those kingdoms respectively with England. The former are elected by the hereditary peers of Scotland descended from Scottish peers at the time of the Union, and sit for one parliament only; the latter are chosen for life by the peers of Ireland, whether hereditary or created since the Union. The power of the crown to create Irish peers is limited by the Act of Union, so that one only can be created when three of the peerages of Ireland have become extinct.

The House of Commons properly consists of 658 members, but St. Albans and Sudbury having been disfranchised, and not having been replaced by any other towns, it now consists of 654 only, distributed as follows:—

ENGLAND AND WALES.

159 knights of shires
337 citizens and burgesses

Total, 496

SCOTLAND.

30 knights of shires
23 citizens and burgesses

Total, 53

IRELAND.

64 knights of shires
41 citizens and burgesses

Total, 105

Total of the United Kingdom, 654.

An account of the changes effected in the parliamentary constituencies at different times, more particularly by the Reform Act, and a full view of the present system of representation, is given in the article COMMONS, HOUSE OF.

The lords and commons originally were one assembly, but the date of their separation is not known. Sir Edward Coke states that he had seen a record, 30 Hen. I. (1130), of their degrees and seats as one body, and affirms that the separation took place at the desire of the commons. (13 'State Trials,' 1410.) Elsynge avers that "the commons ever had a place for their consultation apart from the lords, though they did often meet and sit together in one room," and gives several precedents in support of his position. ('Manner of Holding Parliaments,' pp. 101–104, 155.)

POWER AND JURISDICTION OF PARLIAMENT.

1. LEGISLATIVE AUTHORITY COLLECTIVELY.—The authority of parliament extends over the United Kingdom and all its colonies and foreign possessions. There are no other limits to its power of making laws for the whole empire than those which are common to it and to all other sovereign authority, the willingness of the people to obey, or their power to resist them. It has power to alter the constitution of the country, for that is the constitution which the last act of parliament has made. It may take away life by acts of attainder, and make an alien be as a natural-born subject.

Parliament does not in the ordinary course legislate directly for the colonies. For some, the queen in council legislates, and others have legislatures of their own, and propound laws for their internal government, subject to the approval of the queen in council; but these may afterwards be repealed or amended by direct statutes from this country. Their legislatures and their laws are both subordinate to the mother country.

The power of imposing taxes upon colonies for the support of the parent state was attempted to be exercised by parliament upon the provinces of North America; but this attempt was the immediate occasion of the severance of that great country from our own. The injustice and hardship of colonial taxation must be admitted; but the legal power of parliament to impose such taxes can only be restrained by its own acts conferring constitutions and privileges upon the colonies, which are all subject to its authority.

There are some subjects indeed upon which parliament, in familiar language, is said to have no right to legislate; such for instance as the Church; but no one can intend more by that expression than that it is inexpedient to make laws as to such matters. The very prayers and services of the Church are prescribed by statute. Parliament has changed the professed religion of the country, and has altered the hereditary succession to the throne. To conclude, in the words of Sir Edward Coke, the power of parliament "is so transcendent and absolute, that it cannot be confined, either for causes or persons, within any bounds."

2. DISTRIBUTION OF POWERS BETWEEN KING, LORDS, AND COMMONS.—Custom and convenience have assigned to different branches of the legislature peculiar powers. These are subject to any limitation or even transference which parliament may think fit. The king swears at the coronation to govern "according to the statutes in parliament agreed upon," and these of course may be altered. Prerogatives of the crown which have ever been enjoyed might yet be taken away by the king, with the consent of the three estates of the realm. The king sends and receives ambassadors, enters into treaties with foreign powers, and declares war or peace, without the concurrence of lords and commons; but these things he cannot do without the advice of his ministers, who are responsible to parliament. Without entering into a view of his general prerogatives, which are treated of elsewhere [KING], it will be necessary to advert to certain parliamentary functions exercised by him, and which are most important in the conduct of legislation.

Summons.—It is by the act of the king alone that parliament can be assembled. There have been only two instances in which the lords and commons have met of their own authority, namely, previously to the restoration of King Charles II. and at the Revolution in 1688.

The first act of Charles II.'s reign declared the lords and commons to be the two houses of parliament, notwithstanding the irregular manner in which they had been assembled, and all their acts were confirmed by the succeeding parliament summoned by the king; which however qualified the confirmation of them by declaring that "the manner of the assembling, enforced by the difficulties and exigencies which then lay upon the nation, is not to be drawn into example." In the same manner the first act of the reign of William and Mary declared the convention of lords and commons to be the two houses of parliament, as if they had been summoned according to the usual form, and the succeeding parliament recognised the legality of their acts. But although the king may determine the period for calling parliaments, his prerogative is restrained within certain limits; as he is bound by statute to issue writs within three years after the determination of any parliament; while the practice of providing money for the public service by annual enactments renders it compulsory upon him to meet parliament every year.

There is one contingency upon which the parliament may meet without summons, under the authority of an Act of parliament. It was provided by the 6 Anne, c. 7, that "in case there should be no parliament in being at the time of the demise of the crown, then the last preceding parliament should immediate convene and sit at Westminster, as if the said parliament had never been dissolved." By the 37 Geo. III., c. 127, a parliament so revived would only continue in existence for six months, if not sooner dissolved.

As the king appoints the time and place of meeting, so also at the commencement of every session he declares to both houses the cause of summons by a speech delivered to them in the House of Lords by himself in person, or by commissioners appointed by him. Until he has done this, neither house can proceed with any business.

The causes of summons declared do not make it necessary for parliament to consider them only, or to proceed at once to the consideration of any of them. After the speech, any business may be commenced; and the commons, in order to prove their right to act without reference to any authority but their own, invariably read a bill a first time *pro formâ* before they take the speech into consideration. Other business is also done very frequently at the same time. New writs are issued for places which have become vacant during the recess, returns are ordered, and even addresses are presented on matters unconnected with the speech.

Prorogation and Adjournment.—Parliament, it has been seen, can only commence its deliberations at the time appointed by the king; neither can it continue them any longer than he pleases. He may prorogue parliament by having his command signified in his presence by the lord-chancellor or speaker of the House of Lords to both houses, or by writ under the great seal, or by commission. The effect of a prorogation is at once to suspend all business until parliament may be summoned again. Not only are the sittings of parliament at an end, but all proceedings pending at the time, except impeachments by the commons, are quashed. A bill must be renewed after a prorogation, as if it had never been introduced, though the prorogation be for no more than a day. William III. prorogued parliament from the 21st October, 1689, to the 23rd, in order to renew the Bill of Rights, concerning which a difference had arisen between the two houses that was fatal to it. It being a rule that a bill cannot be passed in either house twice in the same session, a prorogation has been resorted to in other cases to enable a second bill to be brought in.

Adjournment is solely in the power of each house respectively. It has not been uncommon indeed for the king's pleasure to be signified, by message or proclamation, that both houses should adjourn. Either of them however may decline complying with what can be considered as no more than a request. Business has frequently been transacted after the king's desire has been made known, and the question for adjournment put in the ordinary manner.

Dissolution.—The king may also put an end to the existence of parliament by a dissolution. He is not however entirely free to define the duration of a parliament, for after seven years it ceases to exist under the statute of George I., commonly known as the Septennial Act. Before the Triennial Act, 6 Wm. & Mary, there was no limit to the continuance of parliament, except the will of the king. Parliament is dissolved by proclamation, after having been prorogued to a certain day. This practice, according to Hatsell, "which has now been uniform for above a century, has probably arisen from those motives that are suggested by Charles I., in his speech in 1628, 'that it should be a general maxim with kings themselves only to execute pleasing things, and to avoid appearing personally in matters that may seem harsh and disagreeable.'"

In addition to these several powers of calling a parliament, appointing its meeting, directing the commencement of its proceedings, determining them for an indefinite time by prorogation, and finally of dissolving it altogether, the crown has the creation of one entire branch of the legislature; together with other parliamentary powers, which will hereafter be noticed in treating of the functions of the two houses.

The judicial functions of the lords and their right to pass bills affecting the peerage which the commons may not amend, are the only properties peculiar to them, apart from their personal rights and privileges.

Taxation.—The chief powers vested in the House of Commons are those of imposing taxes and voting money for the public service. Bills for these purposes can only originate in that house, and the Lords may not make any alterations in them, except for the correction of clerical errors. On the opening of parliament, the king directs estimates to be laid before the house, but the amount may be varied by the commons at pleasure. Grants distinct from those proposed in the estimates cannot be made without the king's recommendation being signified. The commons will not allow the right of the lords to insert in a bill any pecuniary penalties or to alter the amount or application of any penalty imposed by themselves; but the rigid assertion of this rule was found to be attended with much inconvenience, and a standing order was made in 1831, directing the Speaker in each case to report whether the object of the lords appears to be "to impose, vary, or take away any pecuniary charge or burthen on the subject," or "only to relate to the punishment of offences, and the house shall determine whether it may be expedient in such particular case to insist upon the exercise of their privilege."

On May 21, 1860, the bill for the repeal of the paper duty was thrown out by the House of Lords, after having been passed by the commons. This excited much attention, as it was contended that the power of refusing to repeal a tax was in fact equal to that of imposing one. It was, however, generally agreed that the lords had the power of refusing to pass any bill of which they disapproved. On July 5, the House of Commons, on the motion of Lord Palmerston, unanimously resolved, "1. That the right of granting aids and supplies to the crown is in the commons alone, as an essential part of their constitution; and the limitation of all such grants, as to the matter, manner, measure, and time, is only in them. 2. That although the lords have exercised the power of rejecting bills of several descriptions relating to taxation, by negativing the whole, yet the exercise of that power by them has not been frequent, and is justly regarded by this house with peculiar jealousy, as affecting the rights of the commons to grant the supplies and to provide the ways and means for the service of the year. 3. That to guard for the future against an undue exercise of that power by the Lords, and to secure to the commons their rightful control over taxation and supply, this house has in its own hands the power so to impose and remit taxes, and to frame bills of supply, that the right of the commons as to the matter, manner, measure, and time, may be maintained inviolate."

Right of determining Elections.—Another important power peculiar to the commons is that of determining all matters touching the election of their own members, and involving therein the rights of the electors. Upon the latter portion of this right a memorable contest arose between the Lords and Commons in 1704. Ashby, a burgess of Aylesbury, brought an action at common law against the returning-officers of that town for having refused to permit him to give his vote at an election. A verdict was obtained by him, but a judgment was given against him in the Queen's Bench, which was reversed by the House of Lords upon a writ of error. The commons declared that "the determination of the right of election of members to serve in parliament is the proper business of the House of Commons, which they would always be very jealous of, and this jurisdiction of theirs is uncontested; that they exercise a great power in that matter, for they oblige the officer to alter his return according to their judgment; and that they cannot judge of the right of election without determining the right of the electors, and if electors were at liberty to prosecute suits touching their right of giving voices in other courts, there might be different voices in other courts, which would make confusion, and be dishonourable to the House of Commons; and therefore such an action was a breach of privilege." In addition to the ordinary exercise of their jurisdiction as regarded the right of elections, the commons relied upon an Act of the 7 Will. III., c. 7, by which it had been declared, that "the last determination of the House of Commons concerning the right of elections is to be pursued." On the other hand, it was objected that "there is a great difference between the right of the electors and the right of the elected: the one is a temporary right to a place in parliament *pro hâc vice;* the other is a freehold or franchise. Who has a right to sit in the House of Commons, may be properly cognizable there; but who has a right to choose, is a matter originally established, even before there is a parliament. A man has a right to his freehold by the common law, and the law having annexed his right of voting to his freehold, it is of the nature of his freehold, and must depend upon it. The same law that gives him his right must defend it for him, and any other power that will pretend to take away his right of voting, may as well pretend to take away the freehold upon which it depends." These extracts from the Report of a Lords' Committee, 27th March, 1704, upon the conferences and other proceedings in the case of Ashby and White, give an epitome of the main arguments upon which each party in the contest relied. The whole of this Report, together with another of the 13th March, may be read with great interest.

Encouraged by the decision of the House of Lords, five other burgesses of Aylesbury, now familiarly known as "the Aylesbury men," commenced actions against the constables of their town, and were committed to Newgate by the House of Commons for a contempt of their jurisdiction. They endeavoured to obtain their discharge on writs of *habeas corpus*, but did not succeed. The commons declared their counsel, agents, and solicitors guilty of a breach of privilege, and committed them also. Resolutions condemning these proceedings were passed by the lords; conferences were held, and addresses presented to the queen. At length the queen came down and prorogued parliament, and thus put an end to the contest and to the imprisonment of the Aylesbury men and their counsel.

The question which was agitated at that time has never since arisen. The commons have continued to exercise the sole right of determining whether electors have had the right to vote while inquiring into the conflicting claims of candidates for seats in parliament, and specific modes for trying the right of election by the house have been prescribed by statutes, and its determination declared to be "final and conclusive in all subsequent elections, and to all intents and purposes whatsoever."

Connected with the right of the commons to adjudicate upon all matters relating to elections, may be mentioned their power over the eligibility of candidates. John Wilkes was expelled, in 1764, for being the author of a seditious libel. In the next parliament (February 3, 1769) he was again expelled for another libel; a new writ was ordered for the county of Middlesex, which he represented, and he was re-elected without a contest; upon which it was resolved, on the 17th of February, "that having been in this session of parliament expelled this house, he was and is incapable of being elected a member to serve in this present parliament." The election was declared void, but Mr. Wilkes was again elected, and his election was once more declared void, and another writ issued. A new expedient was now tried. Mr. Luttrell, then a member, accepted the Chiltern Hundreds, and stood against Mr. Wilkes at the election, and, being defeated, petitioned the house against the return of his opponent. The house resolved that although a majority of the electors had voted for Mr. Wilkes, Mr. Luttrell ought to have been returned, and they amended the return accordingly. Against this proceeding the electors of Middlesex presented a petition, without effect, as the house declared that Mr. Luttrell was duly elected. The whole of these proceedings were severely condemned, and on the 3rd of May, 1782, the resolution of the 17th of February, 1769, was ordered to be expunged from the journals as "subversive of the rights of the whole body of electors of this kingdom." A resolution similar to that expunged had been passed in the case of the unfortunate Hall, in 1580, as part of the many punishments inflicted upon him, which we shall have occasion to mention.

Oaths.—The power of administering oaths exercised by the lords is not claimed by the House of Commons. They formerly endeavoured to attain the end supposed to be secured by the administration of an oath, by resorting to the authority of justices of the peace who happened to be members of their own body; but all such expedients have long since been abandoned, and witnesses guilty of falsehood are punished by the house for a breach of privilege, not being amenable to the laws regarding perjury. Election committees have power by statute to administer oaths, and witnesses giving false evidence are guilty of perjury.

3. *Privileges.*—Both houses of parliament possess various rights and privileges for the maintenance of their collective authority, and for the protection, convenience, and dignity of individual members. At the commencement of each parliament, the Speaker, on behalf of the commons, has "laid claim to them of the king" since the reign of Henry VIII., but they appear to have been always enjoyed with equal certainty before that time. Some of them have been subsequently confirmed, modified, and even abolished by acts of parliament, but the petition of the Speaker remains unchanged, and prays for some which have been disallowed by law since the original form was adopted.

Commitment and Fines.—The power of commitment for contempt has always been exercised by both houses. It has been repeatedly brought under the cognisance of the courts, and allowed without question. Mr. Wynn, in his 'Argument,' states that there are upwards of one thousand cases of commitment by the House of Commons to be found in their Journals since 1547. Breaches of privilege committed in one session may be punished by commitment in another, as in the well-known case of Murray, in 1751-2, who was imprisoned in Newgate for a libel until the end of the session, and on the next meeting of parliament was again ordered to be committed; but he had absconded in the meanwhile. Contempts of a former parliament may also be punished. The lords may commit for a definite period beyond the duration of the session of parliament; but a commitment by the commons holds good only until the close of the session.

The House of Lords, in addition to the power of commitment, may impose fines. This privilege is not exercised by the commons, although there is a case in D'Ewes's 'Journal of Queen Elizabeth,' in which Mr. Hall, a member who had incurred their displeasure, by publishing a work "very slanderous and derogatory to the general authority, power, and state of the house, and prejudicial to the validity of its proceedings in making and establishing laws," was ordered to "pay a fine to the queen of five hundred marks." The house at the same time assumed a power not found to have been exercised in other cases. It committed Mr. Hall to the Tower, and ordered that he should remain there for "six months, and until he should made retraction of the book." This punishment was commitment for a time certain without reference to the continuance of the session, and, in the event of a refusal to retract the book, amounted to perpetual imprisonment. A practice still exists which partakes of the nature of a fine. There are certain fees payable by persons committed to the custody of the serjeant-at-arms, and it is usual on discharging them out of custody to attach the condition of the "payment of the fees." These fees are occasionally remitted under particular circumstances—in one case, on account of the poverty of the prisoner.

Freedom of Speech.—Freedom of speech is one of the privileges claimed by the Speaker on behalf of the commons, but it has long since been confirmed as the right of both houses of parliament by statutes. It was acknowledged by an act in the reign of Henry VIII., by which the proceedings of the stannary court with respect to Richard Strode, a member, who was fined and imprisoned by that court for having proposed a bill to regulate the tinners in Cornwall, were declared illegal, and the repetition of similar encroachments upon the privilege of parliament provided against. The language however was thought ambiguous, and it was by limiting its operation to the case of Strode, that a judgment was obtained in the King's Bench against Sir John Elliot, Denzil Hollis, and Valentine, in the reign of Charles I. A true interpretation of the law was subsequently established by resolutions of both houses of parliament, and by a formal reversal of this judgment by the house of lords. The most solemn recognition of the privilege is contained in the Bill of Rights, which declares "that the freedom of speech and debates and proceedings in parliament ought not to be impeached or questioned in any court or place out of parliament."

There are however certain legal incidents to this privilege, which it is necessary to notice. The law presumes that everything said in parliament is with the view to the public good and necessary for the conduct of public business; but should the member publish his speech, he is viewed as an author only, and if it contain libellous matter, he will not be protected by the privilege of parliament. In 1795, an information was filed against Lord Abingdon for libel. His lordship had accused his attorney, in parliament, of improper conduct in his profession. He afterwards published his speech in several newspapers at his own expense. His lordship pleaded his own cause, and contended that he had a right to print what he had, by the law of parliament, a right to speak; but Lord Kenyon said, "that a member of parliament had certainly a right to publish his speech, but that speech should not be made a vehicle of slander against any individual; if it was, it was a libel." In 1813, a much stronger case of the same kind occurred. Mr. Creevey, a member, had made a charge against an individual in the House of Commons, and incorrect reports of his speech having appeared in several newspapers, Mr. Creevey sent a correct report to an editor, requesting him to publish it in his newspaper. A jury found Mr. Creevey guilty of libel, and the court of King's Bench refused an application for a new trial; on which occasion Lord Ellenborough said, "a member of that house has spoken what he thought material and what he was at liberty to speak, in his character as a member of that house. So far he is privileged: but he has not stopped there; but, unauthorised by the house, has chosen to publish an account of that speech in what he has pleased to call a corrected form, and in that publication has thrown out reflections injurious to the character of an individual."

Freedom from Arrest.—The Speaker's petition prays on behalf of the commons, "that their persons, *their estates, and servants*, may be free from arrests and all molestations." These words are not more extensive than the privilege as formerly enjoyed, and instances in which it has been enforced may be found in nearly every page of the earlier volumes of the Journals. This privilege has however been limited by statutes, the last of which (10 Geo. III., c. 50) states in the preamble that the previous laws were insufficient to obviate the inconveniences arising from the delay of suits by reason of privilege of parliament, and enacts that "any person may at any time commence and prosecute any action or suit, &c., against any peer or lord of parliament, or against any of the knights, citizens, or burgesses for the time being, or against any of their menial or any other servants, or any other person entitled to the privilege of parliament, and no such action shall be impeached, stayed, or delayed by or under colour or pretence of any privilege of parliament." Obedience to any rule of the courts at Westminster may be enforced by distress infinite, in case any person entitled to the benefit of such rule shall choose to proceed in that way.

The persons of members are still free from arrest or imprisonment in civil actions, but their property is as liable to the legal claims of all other persons as that of any private individual. Their servants do not enjoy any privilege or immunity whatever.

The privilege of freedom from arrest has always been subject to the exception of cases of "treason, felony, and surety of the peace;" and though in other criminal charges each house may, if it see fit, prevent the abstraction of a member from his parliamentary duties, the case of Lord Cochrane, in 1815, will show how little protection the House of Commons extends to its members in such cases. Lord Cochrane, having been indicted and convicted for a conspiracy, was committed to the King's Bench prison. He afterwards escaped, and was arrested by the marshal while sitting on the privy counsellor's bench in the House of Commons, on the right hand of the chair, at which time there was no member present, prayers not having been read. The committee of privileges declared that by this proceeding of the marshal of the King's Bench "the privileges of parliament did not appear to have been violated so as to call for the interposition of the house."

Courts of justice have committed privileged persons for contempt, and parliament has refused to protect them. By a standing order of the House of Lords, 8th June, 1757, it was declared "that no peer or lord of parliament hath privilege of peerage or of parliament against being compelled by process of the courts of Westminster-hall to pay obedience to a writ of habeas corpus directed to him;" and in the case of Earl Ferrers, it was decided that an attachment may be granted if a peer refuses obedience to the writ of habeas corpus. There have been two more recent cases, that of Mr. Long Wellesley in 1831, and that of Mr. Lechmere Charlton in 1837, in which members committed by the

Lord-Chancellor for contempt have laid claims to privilege, which were not admitted by the House of Commons.

Peers are always free from arrest; and as regards the commons, their privilege is supposed to exist for 40 days after every prorogation, and 40 days before the next appointed meeting.

Jurisdiction of Courts of Law in Matters of Privilege.—In connection with the exercise of privilege, an important point of law arises as to the jurisdiction of courts of justice. Each house of parliament is acknowledged to be the judge of its own privileges. Sir Edward Coke affirms, "whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere." (4 'Inst.') But again, in the disputes in the case of the Aylesbury men, which has been already referred to, the lords communicated to the commons at a conference a resolution "that neither house of parliament have power by any vote or declaration to create to themselves new privileges not warranted by the known laws and customs of parliament," which was assented to by the commons. (14 'Commons' Journals,' 555, 560.) The degree of jurisdiction to be exercised by the courts, and the proper mode of dealing with actions involving matters of privilege, it would indeed be difficult to determine, after the inconsistencies which have been shown in practice and the great variety of opinions expressed by learned men. No more than a concise statement of a few cases will be needed to show the difficulties in which the question is involved.

First, as to the right of courts to inquire into the existence and nature of privileges claimed by either house of parliament. Coke lays it down that "judges ought not to give any opinion of a matter of parliament, because it is not to be decided by the common laws, but *secundum leges et consuetudinem parliamenti*; and so the judges in divers parliaments have confessed." (4 'Inst.,' 15.) When Paty, one of the Aylesbury men, was brought before the Queen's Bench on a writ of habeas corpus, Mr. Justice Powell said "this court may judge of privilege, but not contrary to the judgment of the House of Commons:" and again, "this court judges of privilege only incidentally: for when an action is brought in this court, it must be given one way or other." (2 Lord Raymond, 1105.) The opinions of other judges to the same effect, expressed at different times, might also be given. The words contained in the Bill of Rights, that the "debate and *proceedings* in parliament ought not to be impeached or questioned in any court or place out of parliament," are generally relied upon in confirmation of this doctrine. If this view were always taken of the question, little difference between parliament and the courts of law would arise. The course would be simple. Whatever action might be brought would be determined in a manner agreeable to the house whose privileges were questioned; and if the lords, in case of appeal, were to abide by the same rule, there would be no dissensions. But as such unanimity of opinion has not always existed, there has been a clashing of jurisdictions which nothing probably but a statute can prevent for the future.

A judgment was obtained against Sir W. Williams, the Speaker of the House of Commons, in the second year of James II., for having caused a paper entitled 'Dangerfield's Narrative' to be printed by order of the house. This the house declared to be "an illegal judgment," and against the freedom of parliament. A bill was also brought in to reverse the judgment, but it miscarried in three different sessions. (10 'Commons' Journals,' 177, 205.)

The denial of the exclusive jurisdiction claimed by the commons in 1704, in respect of the right of elections, as stated above, is another important occasion in which the privilege of the commons has clashed with the judgments of legal tribunals.

The only other case which need be mentioned in this place is that of Stockdale *v.* Hansard. In this case an action was brought against the printers for a libel published in the papers printed by the order of the house. The litigation was long and intricate. The house passed certain resolutions, declaring that no court of law had power to decide as to their privileges, but the courts did not hold themselves bound by resolutions only. At length a bill was brought in and passed, by which proceedings, criminal or civil, against persons for publication of papers printed by order of either house of parliament, are to be stayed by the courts, upon delivery of the certificate and affidavit to the effect that such publication is by order of parliament.

Forms of Procedure.

Meeting of Parliament: Preliminary Proceedings.—On the meeting of a new parliament it is the practice for the lord chancellor, with other peers appointed by commission under the great seal for that purpose, to open the parliament by stating "that her Majesty will, as soon as the members of both houses shall be sworn, declare the causes of her calling this parliament; and it being necessary a Speaker of the House of Commons should be first chosen, that you, gentlemen of the House of Commons, repair to the place where you are to sit, and there proceed to the appointment of some proper person to be your Speaker; and that you present such person whom you shall so choose here to-morrow (at an hour stated) for her Majesty's royal approbation." The commons then proceed at once to the election of their Speaker. If any debate arises, the clerk at the table acts as Speaker, and standing up, points to the members as they rise. He also puts the question. When the Speaker is chosen, his proposer and seconder conduct him to the chair, where, standing on the upper step, he thanks the house and takes his seat. It is usual for some members to congratulate him when he has taken the chair. As yet he is only Speaker elect, and as such presents himself on the following day, in the House of Lords, and acquaints the lords commissioners that the choice of the commons has "fallen upon him," that he feels the difficulties of his high and arduous office, and that, "if it should be her Majesty's pleasure to disapprove of this choice, her Majesty's faithful commons will at once select some other member of their house better qualified to fill the station than himself." It is stated by Hatsell, that there have been only two instances "in which neither this form, of having the royal permission to proceed to the election of a Speaker, nor the other, of the king's approbation of the person elected, have been observed. The first is the election of Sir Harbottle Grimstone, on the 25th of April, 1660, to be Speaker of the Convention Parliament which met at the Restoration; the other, is the election of Mr. Powle, 22nd January, 1688-9, in the Convention Parliament at the Revolution." The only instance of the royal approbation being refused is in the case of Sir Edward Seymour, in 1678. Sir John Topham indeed was chosen Speaker in 1450, but his excuse was admitted by the king, and another was chosen by the commons in his place. In order to avoid a similar proceeding on the part of the king, Sir Edward Seymour, who knew that it had been determined to accept his excuse, omitted the usual form.

When the Speaker has been approved, he lays claim on behalf of the commons, "by humble petition, to all their ancient and undoubted rights and privileges," which being confirmed, the Speaker with the commons retires from the bar of the House of Lords.

Both houses then proceed to take the oaths required by law. In the commons the Speaker takes them before any other member. Three or four days are usually occupied in this duty before the sovereign declares to both houses, in person or by commission, the causes of calling the parliament. From this time business proceeds regularly. The first thing usually done in both houses is to vote an address in answer to the speech from the throne.

Before any business is undertaken, prayers are read; in the House of Lords by a bishop, and in the Commons by their chaplain.

Conduct of Business, Divisions, &c.—In the House of Lords business may proceed when three peers are present. In the House of Commons forty members are required to assist in the deliberations. If that number be not present at four o'clock in the afternoon, or if notice be taken, or if it appear on a division that less than that number are present, the Speaker adjourns the house until the next sitting day; but at the morning sittings, which are held on Wednesday for private business, petitions, &c., twenty members are sufficient, and they sit from twelve at noon till six, unless previously adjourned. Towards the end of a session morning sittings are held on other days. The house then meets at twelve, and precisely at six the Speaker adjourns the house, without putting the question, and the business in hand stands as orders of the day for the next sitting. Except on Wednesday or Saturday, on which days there is generally no evening sitting, after the adjournment the house resumes at six o'clock. In both houses all questions are decided by a majority, and none may vote but those present in the house when the question is put, though in the lords proxies are counted if held by a lord who is present. When any question arises upon which a difference of opinion is expressed, it becomes necessary to ascertain the numbers on each side. In the lords, the party in favour of the question are called "content," and that opposed to it, "non-content." In the commons these parties are described as the "ayes" and "noes." When the Speaker cannot decide by the voices which party has the majority, or when his decision is disputed, a division takes place. This is effected now (since 1836 in the commons and 1857 in the lords) by one party being sent to each of the two lobbies attached to either house. All within the house when the question is put must vote. Two clerks are stationed at each of the entrances to the house, holding lists of the members in alphabetical order printed upon large sheets of thick pasteboard so as to avoid the trouble and delay of turning over pages. While the members are passing into the house again, the clerks place a mark against each of their names, and the tellers count the number. This plan has been quite successful; the names are taken down with great accuracy, and very little delay is occasioned by the process.

In committees of the whole house, divisions are taken by the members of each party crossing over to the opposite side of the house, unless five members require that the names shall be noted in the usual manner.

In addition to the power of expressing assent or dissent by a vote, peers may record their opinion and the grounds of it by a "protest," which is entered in the Journals, together with the names of all the peers who concur in it.

When matters of great interest are to be debated in the upper house, the lords are "summoned;" and in the House of Commons an order is occasionally made that the house be called over, and members not attending when their names are called, are reported as defaulters, and ordered to attend on another day, when, if they are still absent and no excuse be offered, they are sometimes committed to the custody of the serjeant-at-arms.

The business which occupies nearly the whole attention of both houses (if we except the hearing of appeals by the lords and the trial of controverted elections by the commons) is the passing of bills; and the mode of proceeding with respect to them may be briefly described in the first place.

BILLS, PUBLIC AND PRIVATE.

Bills are divided into two classes—such as are of a public nature affecting the general interests of the state, and such as relate only to local or private matters. The former are introduced directly by the motions of members; the latter are brought in upon petitions from the parties interested, after the necessary notices have been given and all forms required by the standing orders have been complied with.

With few exceptions, public bills may originate in either house, unless they be for granting supplies of any kind, or involve directly or indirectly the levying or appropriation of any tax or fine upon the people. The exclusive right of the commons to deal with all legislation of this nature affects very extensively the practice of introducing private bills into either house. Thus, all those which authorise the levying of local tolls or rates are brought in upon petition to the lower house. These compose by far the greater part of all private bills. All measures of local improvement, whether for enclosing lands, lighting, watching, and improving towns, establishing police, or making roads, bridges, railways, canals, or other public works, originate in the commons; though in the session of 1860, in consequence of the pressure of business, many bills of this kind were first introduced in the House of Lords. On the other hand, many bills of a personal nature are always sent down from the lords, such as bills affecting private estates, divorce bills. and bills for the naturalisation of aliens. Bills affecting the peerage must originate in the lords, and acts of grace with the crown, where the prerogative of mercy is vested.

Progress of Bills: Public Bills.—Motions for leave to bring in bills of a public nature are not very frequently refused. The more usual time for opposing any measure in its progress is on the second reading, when all the provisions are known, and the general principle and effect of them may be considered. When leave is given to bring in a bill, certain members are ordered to prepare it, being the proposer and seconder of the motion, to whom others are sometimes added. It is then brought in and read a first time, and a day is fixed for the second reading, which generally leaves a sufficient interval for the printing and circulation of the bill.

It has been already said that the second reading is the occasion on which a bill is more particularly canvassed. Its principle is at that time made the subject of discussion, and if it meet with approval, the bill is committed, either to a committee of the whole house or to a select committee, to consider its several provisions in detail. A committee of the whole house is in fact the house itself, in the absence of the Speaker from the chair; but the rule which allows members to speak as often as they think fit, instead of restricting them to a single speech, as at other times, affords great facilities for the careful examination and full discussion of details. The practice of referring bills of an intricate and technical description to select committees has become very prevalent of late years, and might be extended with advantage. Many bills are understood by a few members only, whose observations are listened to with impatience, and thus valuable suggestions are often withheld in the house, which in a committee might be embodied in the bill. By leaving such bills to a select committee, the house is enabled to attend to measures more generally interesting, while other business, of perhaps equal importance, is proceeding at the same time; and it has always the opportunity of revising amendments introduced by the committee.

Before a bill goes into committee there are certain blanks for dates, amount of penalties, &c., which are filled up in this stage. Bills of importance are often recommitted, or in other words, pass twice, and even in some instances three or four times through the committee. When the proceedings in committee are terminated, the bill is reported with the amendments to the house, on which occasion they are agreed to, amended, or disagreed to, as the case may be. If many amendments have been made, it is a common and very useful practice to reprint the bill before the report is taken into consideration. After the report has been agreed to, the bill with the amendments is ordered to be engrossed previous to the third reading. A proposition was made not long since, but without success, for discontinuing the custom of engrossment upon parchment, and for using an examined copy of the printed bill, signed by the clerk of the house, for all the purposes for which the engrossed copy is now required.

The third reading is a stage of great importance, on which the entire measure is reviewed, and the house determines whether, after the amendments that have been made on previous stages, it is fit on the whole to pass and become law. The question, "that this bill do pass," which immediately succeeds the third reading, is usually no more than a form, but there have been occasions on which that question has been opposed, and even negatived. The title of the bill is settled last of all.

An interval of some days usually elapses between each of the principal stages of a bill; but when there is any particular cause for haste, and there is no opposition, these delays are dispensed with, and the bill is allowed to pass through several stages, and occasionally through all, on the same day.

This statement of the progress of bills applies equally to both houses of parliament. There is, however, a slight distinction in the title of a bill while pending in the lords, which is always "intituled an act," whether it has originated in the lords or has been brought up from the commons.

When the commons have passed a bill, they send it to the lords by one of their own members, who is usually accompanied by others. The lords send down bills by two masters in chancery; unless they relate to the crown or the royal family, in which case they are generally sent by two judges.

Private Bills.—In deliberating upon private bills parliament may be considered as acting judicially. The conflicting interests of private parties, the rights of individuals, and the protection of the public, have to be reconciled. Care must be taken, in furthering an apparently useful object, that injustice be not done to individuals, although the public may derive advantage from it. Vigilance and caution should be exercised lest parties professing to have the public interests in view should be establishing, under the protection of a statute, an injurious monopoly. The rights of landowners amongst themselves, and of the poor, must be scrutinised in passing an enclosure bill. Every description of interest is affected by the making of a railway.

The inquiries that are necessary to be conducted in order to determine upon the merits of private bills are too extensive for the house to undertake, and it has therefore been usual to delegate them to committees. To prevent parties from being taken by surprise, the standing orders require certain notices to be given (to the public by advertisement, and to parties interested by personal service) of the intention to petition parliament. The first thing which is done on receiving the petition therefore, is to inquire whether these notices have been properly given, and if all other forms prescribed by the standing orders have been observed. This inquiry is confided to the examiners of private bills, two officers who act for both houses, who report their determination to the house. When a private bill has been read a second time, it is committed, according to its character, to the committee of selection, to the general committee on railway and canal bills, or to the select committee on divorce bills. The committee of selection consists of the chairman of the standing orders committee and five other members nominated by the house, of whom three are a quorum. This committee classifies the bills, and nominates the chairman and members of the committee for each. The railway and divorce committees proceed in the like manner. For every opposed railway, canal, or road bill, the committee consists of five members not interested in the bill in progress. Unopposed bills are referred to the chairman of the committee of ways and means and two other members. The committees on opposed bills may hear counsel and examine witnesses,—divisions amongst the committee are decided by a majority, and the result of their labours is reported to the house.

Public bills are occasionally referred to select committees; these, however, must also pass through a committee of the whole house.

It will not be necessary to pursue any further the progress of private bills, which differs only from that already described in respect of bills of a public nature, in the necessity for certain specified intervals between each stage, and for notices in the private bill office.

In the House of Lords, when a private bill is unopposed, it is committed to the permanent chairman of committees, and any other peers may attend; but when a bill is to be opposed, the committee on standing orders inquires whether the standing orders have been complied with, and if so, the bill is referred to a committee of five, and a similar course is followed to that of the lower house.

In order to ensure a proper acquaintance with the provisions of private bills, some of which are very voluminous, the House of Commons have adopted a rule requiring breviates of the bills to be laid before them six days before the second reading, and breviates of the amendments made by the committee, before the house take the report into consideration.

Conferences between the two Houses.—The progress of bills in each house of parliament having been detailed, it still remains to describe the subsequent proceedings in case of difference between them. When a bill has been returned by either house to the other, with amendments which are disagreed to, a conference is desired by the house which disagrees to the amendments, to acquaint the other with reasons for such disagreement; in order, to use the words of Hatsell, "that after considering those reasons, the house may be induced, either not to insist upon their amendments, or may, in their turn, assign such arguments for having made them, as may prevail upon the other house to agree to them. If the house which amend the bill are not satisfied and convinced by the reasons urged for disagreeing to the amendments, but persevere in insisting upon their amendments, the form is to desire another conference; at which, in their turn, they state their arguments in favour of the amendments, and the reasons why they cannot depart from them; and if, after such second conference, the house resolve to insist upon disagreeing to the amendments, they ought then to demand a 'free conference,' at which the arguments on both sides may be more amply and freely discussed. If this measure should prove ineffectual, and if, after several free conferences, neither house can be induced to depart from the point they originally insisted upon, nothing further can be done, and the bill must be lost."

Whether the conference be desired by the lords or by the commons, the former have the sole right of appointing the time and place of meeting. The house that seeks the conference must clearly express in their message the subject upon which it is desired, and it is not granted as a matter of course. There are many instances to be found in the Journals in which a conference has been refused, but not of late years. The reasons that are to be offered to the other house are prepared by a committee appointed for that purpose, who report them for the approval of the house. These reasons are generally very short, but in some cases arguments have been entered into at considerable length. The conference is conducted by "managers" for both houses, who, on the part of the house desiring the conference, are the members of the committee who have drawn up the reasons, to whom others are occasionally added. Their duty is to read and deliver in the reasons with which they are entrusted to the managers of the other house, who report them to the house which they represent. At a free conference the managers on either side have more discretion vested in them, and may urge whatever arguments they think fit. A debate arose in a free conference, which was held in 1836, in reference to amendments made by the lords to a bill for amending the Act for regulating Municipal Corporations, and the speeches of the managers were taken in short-hand and printed. While the conference is being held, the business of both houses is suspended until the return of the managers.

Amendments made to bills by either house are not the only occasions upon which conferences are demanded. Resolutions of importance, in which the concurrence of the other house is desired, are communicated in this manner. Reports of committees have also been communicated by means of a conference. In 1829 a conference was demanded by the commons to request an explanation of the circumstances under which a bill that had been amended by the lords had received the royal assent without being returned to the commons for their concurrence. The lords expressed their regret at the mistake, and stated that they had themselves been prepared to desire a conference upon the subject, when they received the message from the commons.

Conferences were formerly held in the Painted Chamber, but since the rebuilding of the Houses of Parliament after the fire in 1834, they have been held in one of the lords' committee rooms.

Royal Assent to Bills has been described under ASSENT, ROYAL.

Committees.—Committees are either "of the whole house," or "select." The former are, in fact, the house itself, with a chairman instead of the Lord Chancellor or Speaker presiding. There is a more free and unlimited power of debate when the house is in committee, as members may speak any number of times upon the same question, from which they are restrained on other occasions. Select committees are specially appointed, generally for inquiring into particular subjects connected with legislation. It is usual to give them the "power to send for persons, papers, and records;" but in case of any disobedience to their orders, they have no direct means of enforcing compliance, but must report the circumstance to the house, which will immediately interfere.

In case of an equality of voices, the chairman, who is chosen by the committee out of its own members, gives the casting vote. Some misconception appears to have existed as to the precise nature of the chairman's right of voting. In 1836, the House of Commons was informed that the chairman of a select committee had first claimed the privilege to vote as a member of the committee, and afterwards, when the voices were equal, of giving a casting vote as chairman, and that such practice had of late years prevailed in some select committees; when it was declared by the house that, according to the established rules of parliament, the chairman of a select committee can only vote when there is an equality of voices. (91 'Commons' Journals,' p. 214.) This error was very probably occasioned by the practice of election committees, which was however confined to them, and only existed under the provisions of Acts of parliament.

In 1837 some regulations were made by the House of Commons for rendering select committees more efficient and responsible. The number of members on a committee was limited to fifteen. Lists of their names are to be fixed in some conspicuous place in the committee-clerk's office and the lobby. Members moving for the committee are to ascertain whether the gentlemen they propose to name will attend. To every question asked of a witness, the name of the member who asked it is prefixed in the minutes of evidence laid before the house; and the names of the members present at each sitting, and, in the event of any division, the question proposed, the name of the proposer, and the votes of each member, are entered on the minutes and reported to the house. [COMMITTEES.]

It is not intended to touch upon the elective franchise, or upon the proceedings at elections; but the mode of trying election petitions will require a notice in this place.

Trial of Election Petitions.—Before the year 1770, controverted elections were tried and determined by the whole House of Commons, as mere party questions, upon which the strength of contending factions might be tested. In 1741, Sir Robert Walpole, after repeated attacks upon his government, was at last driven from office by a vote upon the Chippenham election petition. "Instead of trusting to the merits of their respective causes," said Mr. Grenville, in proposing the measure which has since borne his name, "the principal dependence of both parties is their private interest among us, and it is scandalously notorious that we are as earnestly canvassed to attend in favour of the opposite sides, as if we were wholly self-elective and not bound to act by the principles of justice, but by the discretionary impulse of our inclinations; nay, it is well known that in every contested election, many members of this house, who are ultimately to judge in a kind of judicial capacity between the competitors, enlist themselves as parties in the contention, and take upon themselves the partial management of the very business upon which they should determine with the strictest impartiality." The principle of the Grenville Act, and of others which were passed at different times since 1770, was to select committees for the trial of election petitions by lot. By the last of these (9 Geo. IV., cap. 22), thirty-three names were balloted from the members present at the time, and each of the parties to the election was entitled to strike off eleven names, and thus reduce the number of the committee to eleven. Whichever party attended on the day appointed for a ballot in the greatest force, was likely to have a preponderance in the committee, and the expedient of chance did not therefore operate as a sufficient check to party spirit in the appointment of election committees. Partiality or incompetence was very generally complained of in the decisions of committees appointed in this manner, and in 1839 an Act passed establishing a new system, upon different principles, increasing the responsibility of individual members, and leaving scarcely anything to the operation of chance.

The following is an outline of the present mode of selecting members for the trial of election petitions:—At the beginning of a session the Speaker appoints a general committee of six members, to any or all of whom the house may object, in which case the Speaker is bound to appoint others. If by irreconcileable disagreement of opinion, or by the continued absence of more than two members, the committee, when appointed, should be unable to proceed in the discharge of its duties, or if the house should determine that it shall be dissolved, its functions are to cease. To this general committee all election petitions are referred. The names of all the members of the house are put into an alphabetical list and called over, when certain excuses are allowed to be made; but all who do not then excuse themselves from serving are bound to act as members of election committees when hereafter chosen. This list is taken by the general committee, from which are elected six, eight, ten, or twelve members, but in no case to exceed eighteen, who, on signifying their willingness to serve, are formed into "the chairman's panel." The list is then divided into five panels by the general committee, exclusive of the chairman, the order of which is decided by lot, and a number attached to each in the order in which it is drawn. These panels are to be corrected from time to time by the general committee, according to circumstances. The general committee gives three weeks' notice to the parties before it proceeds to appoint a committee for the trial of an election petition. At the expiration of that time it chooses, from the panel standing first in order of service, four members, whose names are read to the parties, who have power to object to any of them on grounds of disqualification specified in the Act. When the four members are finally chosen, the chairman's panel appoint one of their own body to act as chairman, who is added accordingly to the general committee. The committee, when thus completed, is sworn, and proceeds to business. All questions are decided by a majority.

As witnesses giving false evidence before an election committee are guilty of perjury, it is usual for the house, when acquainted with such misconduct, to instruct the attorney-general to prosecute the parties. The same course has also been pursued with respect to persons proved to have been concerned in bribery.

The determinations of election committees are final, and are immediately carried into effect by the house. If an election be reported void, a new writ is issued; if it be decided that a member has not been duly elected, and that another candidate should have been returned, the deputy clerk of the crown is ordered to attend and amend the return, after which the new member is sworn, and takes his seat; and if a petition or the opposition to it be held by the committee to have been frivolous and vexatious, the petitioner or sitting member, as the case may be, is liable to the payment of all the costs.

The last proceeding in parliament which we shall describe is that of

Impeachment.—Impeachment by the commons is a proceeding of great importance, involving the exercise of the highest judicial powers by parliament; and though in modern times it has rarely been resorted to, in former periods of our history it was of frequent occurrence. The earliest instance of impeachment by the commons at the bar of the House of Lords was in the reign of Edward III. (1376). Before that time the lords appear to have tried both peers and commoners for great public offences, but not upon complaints addressed to them by the commons. During the next four reigns, cases of regular impeachment were frequent; but no instances occurred in the reigns of Edward IV., Henry VII., Henry VIII., Edward VI., Queen Mary, or Queen Elizabeth. The constitution "had fallen into disuse," says Mr. Hallam, "partly from the loss of that control which the commons had obtained under Richard II. and the Lancastrian kings, and partly from the preference the Tudor princes had given to bills of attainder or of pains and penalties, when they wished to turn the arm of parliament against an obnoxious subject." Prosecutions also in the Star-Chamber during that time were perpetually resorted to by the crown for the punishment of state offenders. In the reign of James I., the practice of impeachment was revived, and was used with great energy by the commons, both as an instrument of popular power and for the furtherance of public justice. Between the year 1620, when Sir Giles Montresser and Lord Bacon were impeached, and the Revolution in 1688, there were about forty cases of impeachment. In the reigns of William III., Anne, and George I., there were fifteen; and in George II. only one (that of Lord Lovat, in 1746, for high treason). The last memorable cases are those of Warren Hastings, in 1788, and Lord Melville, in 1805.

An outline of the forms observed in the conduct of impeachments may be briefly given. A member of the House of Commons charges the accused of certain high crimes and misdemeanors, and moves that he be impeached. If the house agree to it, the member is ordered to go to the lords, and at their bar, in the name of the House of Commons and of all the commons of the United Kingdom, to impeach the accused. A committee is then ordered to draw up articles of impeachment, which are reported to the house, and, having been discussed and agreed upon, are engrossed and delivered to the lords. Further articles may be delivered from time to time. In the case of Warren Hastings, the articles had been prepared before his impeachment at the bar of the House of Lords. The accused sends answers to each article, which are communicated to the commons by the lords; to these, replications are returned if necessary. After these preliminaries, the lords appoint a day for the trial. The commons desire the lords to summon the witnesses required to prove their charges and appoint managers to conduct the proceedings. Westminster Hall has been usually fitted up as the court, which is presided over by the lord high steward. The commons attend with the managers as a committee of the whole house. The accused remains in the custody of the usher of the black rod, to whom he is delivered, if a commoner, by the serjeant-at-arms attending the House of Commons. The managers should confine themselves to charges contained in the articles of impeachment. Mr. Warren Hastings complained of matters having been introduced which had not been originally laid to his charge, and the house resolved that certain words ought not to have been spoken by Mr. Burke. Persons impeached of high treason are entitled, by statute 20 Geo. II. c. 30, to make their full defence by counsel, a privilege which is not denied to persons charged with high crimes and misdemeanors.

When the managers have made their charges and adduced evidence in support of them, the accused answers them, and the managers have a right to reply. The lords then proceed to judgment in this manner: The lord high steward puts to each peer, beginning with the junior baron, the question upon the first article, whether the accused be guilty of the crimes charged therein. The peers in succession rise in their places when the question is put, and, standing uncovered, and laying their right hands upon their breast, answer "guilty," or "not guilty," as the case may be, "upon my honour." Each article is proceeded with separately in the same manner, the lord high steward giving his own opinion the last. The numbers are then cast up, and being ascertained, are declared by the lord high steward to the lords, and the accused is acquainted with the result.

(*A Treatise on the Law, Privileges, Proceedings, and Usages of Parliament*, by T. E. May, Esq., fourth edit., 1859.)

PARLIAMENT OF IRELAND. In Ireland, as in England, from the conquest of the country by Henry II. in the latter part of the 12th century, meetings of the barons were occasionally summoned to consult on public affairs, to which the old historians sometimes give the name of parliaments. But parliaments, in the modern sense, cannot be traced back in Ireland farther than to the latter end of the 13th century, or to a date about thirty years subsequent to that of the earliest parliament which is ascertained to have consisted both of lords and commons in England. Simon de Montfort's celebrated parliament, the first for which writs are extant summoning representatives of the counties and boroughs, met at Westminster in 1265; and the first Irish parliament to which, as far as is known, the sheriffs were directed to return two representatives for each county was held in 1295. Representatives of boroughs in Ireland cannot be traced much higher than to the middle of the 14th century. They first make their appearance in 1341, and in an act or ordinance of 1359 they are spoken of as forming an essential part of the parliament.

At this time, however, and down to a much later date, it was only the small portion of Ireland occupied by the English settlers that was represented in the legislature. Even in the reign of Edward III. only the province of Munster and a part of Leinster were considered as shire-land; they were divided into twelve counties. But in the course of the 15th century much the greater part of these districts had become to all intents and purposes independent of the English crown; and in the reign of Henry VII. the English dominion and the parliamentary representation were alike confined to the counties composing what was called the Pale, that is, to those of Dublin, Louth, Kildare, and Meath (then comprehending both East and West Meath), with a very few seaports beyond these limits. The vigorous measures taken under Henry VIII. and succeeding kings however gradually extended the authority of the English institutions and laws. The possessors of some of the original Irish peerages, after maintaining for centuries an independence as complete as that of the native chieftains themselves, were induced to give their attendance in the House of Lords, and many new peerages were conferred, some on Englishmen or persons of English descent, some on the heads of the old Irish families. The twelve ancient counties were all reclaimed in the reign of Henry VIII., and others were added by Mary, Elizabeth, and James, till, in the time of the last-mentioned king, the whole island was divided into thirty-two counties, as at present, each returning two representatives. Of these thirty-two counties however it is said there were seventeen in which there was not a single parliamentary borough, while in the remaining fifteen there were only about thirty. But either this account must be wrong or the common statement that James added only forty new boroughs must be an under statement, if, as appears, the entire number of the Irish commons in 1613 was 232. In this number however would be included the two representatives of Trinity College, Dublin. Subsequent new charters to boroughs augmented the house by the year 1692 to 300, at which number it remained stationary. In 1634 the number of peers was 122, and more than 500 Irish peerages were created between that date and the Union. Of course however some also became extinct.

It was only for a very short period of its existence that the Irish parliament was held to be a supreme legislature. Ireland being regarded as a conquered dependency, it was maintained that its parliament was in all respects subordinate to that of England, and subsequently to that of Great Britain, which might make laws to bind the people of the one country as well as of the other. The received legal doctrine used to be, that King John, in the 12th year of his reign (A.D. 1210), ordained by letters-patent, in right of dominion of conquest, that Ireland should be governed by the laws of England; in consequence of which both the common law of England and all English statutes enacted prior to that date were held to be of the same authority in Ireland as in England. With regard to English acts passed subsequently to that date, it was also held, in the first place, that Ireland was bound by all of them in which it was either specially named or included under general words. But further, inasmuch as one of the Irish acts called Poyning's Laws, passed in the tenth year of Henry VII. (A.D. 1495), in the lord-lieutenancy of Sir Edward Poyning, or Poynings, declared that all statutes "lately" made in England should be deemed also good and effectual in Ireland, it was held that this established the authority in Ireland of all preceding English statutes whatsoever; making those of the 12th of John of the same force with those enacted before that date. This however was admitted to be the last general imposition of the laws of England upon Ireland. Of the English statutes passed since the 10th of Henry VII., it was allowed that those only were binding upon Ireland in which that country was specially named or included under general words.

But the above-mentioned was only one of Poyning's laws. Others provided, as their substance is given by Blackstone (1 'Com.' 102); "1. That before any (Irish) parliament be summoned or holden, the chief governor and council of Ireland shall certify to the king, under the great seal of Ireland, the considerations and causes thereof, and the articles of the acts proposed to be passed therein. 2. That after the king, in his council of England, shall have considered, approved, or altered the said acts, or any of them, and certified them back under the great seal of England, and shall have given licence to summon and hold a parliament, then the same shall be summoned and held; and therein the said acts so certified, and no other, shall be proposed, received, or rejected." It was found, however, in the course of time, that many inconveniences were occasioned by these severely restrictive regulations, which prevented any laws from being proposed, except only such as were drawn up before the parliament which should pass them was in being; and therefore, by the 3 & 4 Ph. and M., c. 4., it was provided that any new propositions might be certified in England for approval, even after the summons and during the session of parliament. Still this left to the parliament of Ireland nothing more than merely the power of rejecting any law proposed to it; it could neither initiate a new law nor repeal an old one, nor even amend or alter that which was offered for its acceptance. In practice, however, the letter of the statute was somewhat relaxed. Blackstone goes on to state that the practice in his day (some years after the middle of the last century) was, "that bills are often framed in either house, under the denomination of 'heads for a bill or bills,' and in that shape they are offered to the consideration of the lord-lieutenant and privy-council, who, upon such parliamentary intimation, or otherwise upon the application of private persons, receive and transmit such heads, or reject them without any transmission, to England." These heads of bills however really differed in nothing from bills or acts of parliament, except that, instead of the words "Be it enacted," the formal commencement of each paragraph or clause was, "We pray that it may be enacted;" and the motion for presenting them scarcely differed, except in form, from the motion in the English House of Commons for leave to bring in a bill, a motion necessary in all cases to be assented to or carried in the affirmative before the actual bringing in of any bill. And as for the consent of the crown or the government, which it was necessary to obtain before either house of the Irish parliament could take up the consideration of any proposed law, with a view to its enactment, that would in practice probably be found to operate much in the same way with the assent of the crown, which even in England was necessary to give validity to any bill after it had passed both houses. In the Irish as well as in the English parliament there was in fact an opportunity of discussing the proposition without the permission of the crown. An English as well as an Irish bill required the assent of the crown before it could become law. This view of the matter has scarcely been sufficiently attended to in comparing the circumstances of the two legislatures. The practice of presenting heads of bills however was not introduced into the Irish parliament till after the Revolution. In the reign of Charles II., according to Lord Mountmorres, "the council framed bills altogether; a negative alone on them and their several provisos was left to parliament; only a general proposition for a bill, by way of address to the lord-lieutenant and council, came from parliament:" that is to say, all that the parliament was suffered to do was simply to request that some measure might be brought in for effecting a particular object. The object might be specified, but the means by which it was to be attained or attempted, in other words, the details and whole character of the measure, were to be left to the government. With regard to these, the parliament had only the power of accepting or rejecting them in the mass.

But the dependence of Ireland upon the English crown, and the consequent subordination of the Irish legislature, were held to go still farther than to the establishment of the principle that laws might be made by the parliament of England to bind Ireland. The Irish House of Lords had entertained writs of error upon judgments in the courts of common law from the reign of Charles I., and appeals in equity from the Restoration. Nevertheless, in the year 1719, a judgment in the Court of Exchequer having been reversed by the House of Lords, the question was carried to the House of Lords of Great Britain, by which the judgment of the Court of Exchequer was affirmed. On this the Irish House of Lords resolved that no appeal lay from the Court of Exchequer in Ireland to the parliament of Great Britain. But this resolution was immediately met by an act of the British parliament, the 5 Geo. I. c. 1, declaring that "the king's majesty, by and with the advice and consent of the lords spiritual and temporal of Great Britain in parliament assembled, had, hath, and of right ought to have full power and authority to make laws and statutes of sufficient force and validity to bind the people and the kingdom of Ireland; and that the House of Lords of Ireland have not nor of right ought to have any jurisdiction to judge of, reverse, or affirm any judgment, sentence, or decree given or made in any court within the said kingdom; and that all proceedings before the said House of Lords upon any such judgment, sentence, or decree are and are hereby declared to be utterly null and void to all intents and purposes whatsoever."

In this state the law remained till the year 1782. In that year the statute 5 Geo. I. c. 1, was repealed by the 22 Geo. III. c. 53; and the following year the 23 Geo. III. c. 28, declared the exclusive right and authority of the Irish parliament and courts of justice in all matters of legislation and judicature for Ireland. Finally, in 1800, by the Act of Union, the 39 & 40 Geo. III. c. 67, the Irish parliament was extinguished, and it was enacted that the United Kingdom should be represented in one and the same parliament, to be called the parliament of the United Kingdom of Great Britain and Ireland.

The earliest Irish statutes on record are of the year 1310; but from that date there are none till the year 1429, from which time there is a regular series. The whole have been printed, and there are also abridgments by Bullingbroke and Belcher, Hunt, and others.

(Wakefield's *Account of Ireland*; Hallam's *Constitutional History of England.*)

PAROCHIAL REGISTERS. [Registration of Births, &c.]

PARODY (from the Greek *παρῳδία*, and that from *ᾠδή*, an ode). A parody is a pleasantry, which consists in turning what is intended as a serious composition into ridicule, by adapting it to some new purpose, or by the affected imitation of its peculiarities. It had its origin among the Greeks, from whose language the name is derived. It seems to be synonymous with the French *travestie*. Its most common form is that in which a performance, while its principal features are retained, is, by a slight change, diverted from its proper design, and made to bear a ludicrous signification. Sometimes the alteration of a single word, or even a single letter, is sufficient for the accomplishment of this. Another form of parody is that in which, without any change in the original, it receives a ludicrous character by its application to some object quite foreign to the original intention of the author. A third kind consists in choosing a mean and ridiculous subject, and treating it in the style and manner of approved writers; and a fourth, in exemplifying, in the illustration of any subject, the defects and absurdities of writers held in little esteem. Of the last two sorts of parody, more successful specimens will scarcely be found anywhere than those which occur in the work entitled 'Rejected Addresses.' The rules of parody have respect to the choice of the subject and the mode of handling it. It is necessary that the subject should be celebrated, or at least well known, and that in treating it there should be no departure from the requirements of good humour.

The term parody is also employed in music, and is given by the French writers to those pieces in which the words have been composed for the music and not the music for the words.

PAROL. This term, which signifies "a word," has been adopted from the Norman-French as a term of art in English law, to denote verbal or oral proceedings, as distinguished from matters which have been recorded in public tribunals or otherwise reduced to writing. Thus a parol contract is an agreement by word of mouth, as opposed to a contract by deed. Parol evidence is the testimony of witnesses given orally, as opposed to records or written instruments. This is the popular acceptation of *parol*; but, strictly speaking, everything, even in writing, is parol which is not under seal.

The formal allegations of the parties to a suit in the common law courts, called pleadings, which are now made in writing, were formerly conducted orally at the bar, and in the year-books are commonly denominated the *parol*. Hence in certain actions brought by or against an infant, either party may suggest the fact of the infancy, and pray that the proceedings may be stayed; and where such a suggestion was complied with, the technical phrase was that the *Parol demurred* (demoratus), that is, the pleadings were suspended until the infant had attained his full age.

PAROLE, the countersign, the pass word, or watch-word, given to guards and sentries in camp and garrison, and demanded by them of all who approach their posts, and on giving which alone they permit them to pass; also the promise, on honour, to reappear when called upon, given by a prisoner of war when allowed to go at large.

PARSLEY. The garden parsley (*Petroselinum sativum*) is a hardy biennial, a native of Sardinia, introduced into this country about the middle of the 16th century. There are three varieties, two of which are well known, and commonly used as pot-herbs, and for garnishing, namely: the *common* or *plain-leaved*; the *curled*; and the *Hamburg, large* or *carrot-rooted*, which last is cultivated only for its roots, occasionally used as young carrots. The curled variety is by far the most useful, and from its beautiful curled foliage it cannot be mistaken for the *Æthusa Cynapium*, or fool's parsley, a poisonous plant somewhat resembling the plain-leaved parsley. [Æthusa, in Nat. Hist. Div.]

The cultivation is simply that of sowing, usually in spring, in shallow drills about a foot apart; or in single rows along the borders of a kitchen-garden. The Hamburg requires to be sown in light and moist soil, such as would suit the carrot, like which it requires in all respects to be treated.

PARSNIP. The cultivated parsnip (*Pastinaca sativa*) is a native of England, and ranks amongst the hardiest of kitchen-garden productions, as is proved by the fact of its having withstood the intense frost of 1838, in the open ground. There are four varieties, namely, the *Common*, *Guernsey*, *Hollow-crowned*, and *Round* or *Turnip-rooted*. The Hollow-crowned has been found the best. The mode of culture is very simple. The soil ought to be deep and rather light, but by no means adhesive; and it should be trenched to the depth of at least two feet. In order that the roots may be clean and sound, fresh manure should not be applied; indeed if the soil be in tolerably good condition, no manure is required; and on the contrary, if it be poor, a more liberal supply should be given in the previous season, so that any immediate application along with the parsnip crop is not requisite.

The seed should be sown in March, and as early in that month as the weather and state of the soil will permit, in shallow drills eighteen inches apart, the plants being afterwards thinned to from 8 inches to a foot asunder in the rows. The roots are not in perfection for culinary purposes till their first season's growth is completed, which is indicated by the decay of the greater part of the leaves.

Some may be then taken up, their tops cut off, but not too closely, and the roots stored in sand in a cool place, so as to guard against the stimuli of light and heat as much as possible. This precaution of storing in the early part of winter is only necessary in case of frost becoming so severe as to render the operation of removal difficult; but the whole of the crop should be taken out of the ground before vegetation recommences in the spring, and treated as above.

Besides the use of the roots for the kitchen, a wine is sometimes prepared from them. Abounding in saccharine matter, they afford by distillation an ardent spirit, the process of fermentation being facilitated by the addition of a small portion of malt liquor.

The large Guernsey parsnip will yield under good cultivation 10 or 12 tons per acre of a most nutritive food for cows and pigs, for which the roots should be steamed or boiled.

PARSON. [Benefice.]

PARTHENON. [Athens, in Geog. Div.]

PARTICIPLE (in Grammar), the name of one of the parts of speech into which grammarians have distributed the words of a language. The word "participle" comes from the Latin word "participium," which is formed on the same analogy as "mancipium" and "principium," and means literally "part-taking." It is said, according to the old grammarians, to have obtained this name in consequence of its partaking of the nature both of the verb and the noun. Horne Tooke defines a participle to be a "verb adjective," which is perhaps as good a definition as can be given.

The English language has only two participles, which are usually called present and past. The present participle in *ing*, is a corruption of a fuller form which had a prefixed *a*; and this *a* was in truth an abbreviation of the old preposition *an*, signifying *in* or *on*. Thus, "he was a-walking" contains the same element as "he was a-bed;" and the word *walking* is merely one of the familiar substantives in *ing*. The Keltic languages form their participle in a way precisely similar; and the French too has inherited from this source the idiom *en disant.* The term *present* participle is however not very correct, as it often denotes the continuation of an action or a state of being independent of the notion of time. A better phrase is *imperfect* participle. This participle is called by some grammarians the *active* participle, but it is also passive; thus in the expression "he was building the house," the participle is active; but when we say "the house was building," it must be regarded as a passive. In such sentences as the preceding there is no ambiguity, but when we say "the man was killing," the knowledge of the subject can alone enable us to determine whether the man was active or passive. This ambiguity in the use of the participle in *ing* has led to the modern practice, which is gaining ground, of expressing the notion of a passive participle by means of the present participle of the verb "to be" and the past tense of the verb which is to be employed, as "being loved," "being praised," &c., which expressions are certainly very awkward and unwarranted by the usage of our best writers, if they are not absolutely wrong.

The other participle in English is used to denote past time, and is generally formed by adding *en* or *ed* and *d*, as *brok-en*, *praise-d*, &c.

PARTICLE, which is derived from a Latin word (*particula*) meaning a small part, is a term employed in grammar, but with rather an uncertain signification. Some of the old grammarians included under this name all the parts of speech except the verb and the noun, namely, prepositions, adverbs, conjunctions, and interjections. Words of this class are included under the term of "particles" by the Arabic grammarians. According to this definition, such words as "vehementer," "unexpectedly," &c., would be considered particles; which is certainly contrary to the common notion which we attach to a particle. In fact we seem to regard as particles all those small words which serve to make the sense of a proposition more clear and precise, though they might sometimes be omitted without rendering the meaning unintelligible. To this class of words belong the Greek *γε, αρα, τοι, δη, νυν*, &c., the English *when, yet, in, and, then, now*, &c.

PARTITION. [PARCENERS.]

PARTITION TREATIES. [TREATIES, CHRONOLOGICAL TABLE OF.]

PARTNERSHIP may be defined to be a contract between two or more persons for joining together their money, goods, labour, and skill, or any or all of them, upon an agreement that the gain or loss shall be divided between them; and its object must be some legal trade or transaction. The English law of partnership is founded on the common law, the so-called law of merchants, and the Roman law. By the common law, a partner has no power to bind his co-partner by deed. By the law of merchants, he has power to bind his co-partner by a bill of exchange, and there is no survivorship in the partnership stock. From the Roman law is derived the principle that a partnership is terminated by the death of a partner. (Gaius, iii. 155.)

If the judges have any doubt about the custom of merchants, they may send to them to know their custom, as they may send for the civilians to know their law; but the judges only recognise those customs of merchants that are general, not those that are particular usages.

We have here to speak of private unincorporated partnerships, to constitute which no writing is necessary. The acts of the parties, when there is no partnership contract in writing, are the evidence of the contract. Partners may be either ostensible, nominal, or dormant. He whose name appears to the world as a partner is an ostensible partner. An ostensible partner may or may not have an interest in the concern; if he has no interest in the concern, but allows his name to appear as one of the firm, he is a nominal partner; if his name and transactions as a partner are purposely concealed from the world, he is a dormant partner; but if his name and transactions are actually unknown to the world, he is more properly termed a secret partner. Generally speaking, any number of persons may be partners; but there are some exceptions, for which see the article on JOINT STOCK COMPANIES.

Any person of sound mind and not under any legal disability may be a partner. An infant may enter into this, as into any other trading contract which may possibly turn out to his advantage. It may, however, be avoided by him on coming of age, though the person with whom he contracts will be bound. An alien friend may be a trader and sue in personal actions, and may therefore be a partner. But an Englishman domiciled in a foreign country at war with England, or an alien enemy, cannot be a partner with a person in this country; at least he cannot sue in this country for a debt due to the firm. Married women are legally incapacitated from entering into the contract of partnership; and although they are sometimes, under positive covenants, entitled to shares in banking-houses and other mercantile concerns, yet in these cases their husbands are entitled to such shares, and become partners. If parties share in the profit and loss they are partners, although one may bring into the trade money, another goods, and a third labour and skill, which was also the rule of the Roman law (Gaius, iii. 149); and where one party is sole owner of goods and another sole disposer or manager of them, if they share the profits, they are partners in those profits. Every man who has a share of the profits of a trade must also bear his share of the loss; for a right to a share of the profit legally implies a liability to bear a share of the loss. Yet it is not necessary to the partnership contract that every party should undertake to share the loss, for one may stipulate to be free from all liability to loss, and such stipulation will hold good as between himself and his co-contractors, which was also the rule of the Roman law, though he will still be liable to all those who have dealt with the firm of which he is a member. Persons who jointly purchase goods are not partners unless they are jointly concerned in the profit or the produce arising from the sale of them. It is not necessary that the division of profit and loss among partners should be equal: it is sufficient that the parties share the profits, in order to render them partners. If they share the profits, they are by consequence bound to share the losses. But to constitute a man a partner on the ground of sharing profits, he must have an interest in the profits, as a principal in the firm; if he only receive a portion of the profits, by way of payment for his labour, trouble, or skill as a servant or agent of the concern, he is not a partner. Factors and brokers who receive a commission out of the profits of goods sold by them are not on that account partners with their principals; nor are persons who receive a certain share of the profits of an adventure, as payment in lieu of wages for acting as servants, partners in the adventure; nor even are persons who receive wages in proportion to the profits of the undertaking considered as partners. If a person lend money to a firm, and receives an annuity or interest, certain as to amount and duration, he is not a partner; but if he were to receive an annuity in lieu of the profits of the trade, and determinable on the event of the trade ceasing, it seems that he would be considered as a partner with the grantor of the annuity; or if he received an annuity varying in amount with the profits, he would be clearly a partner in the concern.

The contract of partnership must be formed for the purpose of some lawful trade, business, or adventure. If the subject of the contract be illegal, there can be no partnership founded upon it, so as to give the contractors a remedy against each other, or against third persons, at law or in equity; and if there be an illegal contract of partnership which is not executed, but executory only, none who are parties to it can by action or suit recover the money advanced for the purpose of establishing the partnership. A contract originally entered into for the purpose of evading the usury laws, and not *bonâ fide* with the view of partnership, could not, while those laws existed, be supported as a legal contract; nor can a partnership between attorneys, where one of them is not duly qualified, be sustained.

A person may stipulate not to be a partner, but if he shares the profit with those with whom he stipulates, he becomes a partner so far as relates to his liability to a third party. And if persons be known to share the profits of a trade, it is presumed that they are partners, and as such liable to all who deal with the firm, whatever be the private agreement among themselves. But they may repel the presumption of partnership by showing that the legal relation of partnership among themselves does not exist. If a person allow his name to be used in a business, or in any other way consent to appear as a partner, he will be so considered with respect to other persons, whatever may be his agreement with the firm; and he will be equally responsible to third parties with the other partners, although he may not receive or be entitled to receive any of the profits. The ground of this rule of law is clear and reasonable: a person must be considered bound by a contract, if he act in such a way as to make other contracting parties believe that he is a party to the contract; and such is the case with a man who allows his name to appear as a member of a firm, as to all contracts and dealings which are necessary for carrying on the business of the firm.

A partnership at will is one which continues as long as the parties live and are able and willing to continue it; a partnership for a fixed term continues for the term if the parties live and are of legal capacity to continue it. A partnership at will may be dissolved at any time by the express will of any member of it, a rule which is derived from the Roman law, and which is a necessary consequence of the nature of the partnership contract. In such case the partnership is dissolved immediately upon notice given by any of the partners. The effect of such dissolution is to stop all new partnership dealings or contracts; but the partnership still continues for the purpose of completing all contracts already made, and all dealings or undertakings already commenced. On such dissolution, any partner is entitled to have the whole partnership stock, and the interest in the premises on which the business is carried on, converted into money, and to receive his share of the produce. In all cases, by the natural death of a partner, the partnership is dissolved, a rule also derived from the Roman law, as already stated: it is also dissolved by a partner's civil death, as his outlawry, or attainder for treason or felony; for an outlaw, being dead in law, incapable of entering into any contract, bringing any suit, or holding any property, a partnership in which he is engaged is therefore dissolved; and, strictly speaking, the whole property is forfeited to the crown; for as the king never becomes joint tenant, or tenant in common with the other partner, the crown takes the whole; but this right is seldom enforced against creditors or innocent partners. A marriage of a feme-sole trader is also a dissolution of a partnership at will. A partnership for a term may be dissolved before its expiration by the mutual consent of the parties, by the decree of a court of equity, or by the bankruptcy, outlawry, or felony of any of the partners. A court of equity will in some cases dissolve a partnership on the ground of incurable insanity in one of the partnership. A partner may agree that upon his death the business may be carried on beyond the legal period of dissolution in the hands of his children or other third parties; but this is properly an agreement for a new partnership. Partners cannot be relieved from future liabilities to third parties without notice to them and to the world in general that the partnership has ceased; but in the case of a dormant partner, if none of the creditors know that he is a partner, no notice of his retirement from the firm is necessary; and if it be known to some, notice to such only will be sufficient. On the death of a partner, notice of the dissolution to third parties is unnecessary.

Partners are joint tenants in the stock and all effects; yet there is no survivorship in equity, or, as it has been said, at law, in such part of the stock as is moveable. Upon the decease of a partner, his personal representatives become entitled to his share of the moveable stock and effects, and they thereupon become in equity, and, as it has been said, at law, tenants in common with the surviving partners. If, as is generally the case in the purchase of lands for the purposes of a partnership, they are conveyed to the partners as tenants in common, and one of the partners should die intestate, the legal estate in his share will descend to his heir, who will be tenant in common with the other partners. If the lands were conveyed to them as joint tenants, there will be no survivorship in equity; and it becomes then a question whether, upon the death of a joint trader, who, with his partners, has so purchased lands for the purpose of the trade, his share will descend for the benefit of his heir or his next of kin; and the better opinion seems to be (see Darby *v.* Darby, 3 Drew, 499), that although the legal estate in freehold property purchased by partners for the purposes of their trade will go in the ordinary course of descent, yet the equitable interest will be held to be part of the partnership stock, and distributable as personal estate. It is scarcely necessary to observe, that upon the purchase of lands, they may be expressly conveyed so as to be always held as real estate, and descend to the heirs of the several partners.

It sometimes happens that one person supplies goods for an adventure, and another only his time, trouble, and credit; yet if in the agreement between the parties there are words which imply a joint undertaking, those words are evidence of an intention to share jointly the goods and also the profits of them.

There is an implied obligation, in the absence of express stipulation, among partners to use the property for the benefit of all of them: and any fraud on the part of one partner, either by misapplication of the partnership fund or in any other way, is a matter of which a court of equity will take cognisance. No partner has a right to engage in any business or speculation which must necessarily deprive the partnership of his time, skill, and labour, because it is the duty of each to devote himself to the interest of the firm. It is the duty of each partner to keep precise accounts, and to have them always ready for the inspection of his co-partner. Each partner is liable to the performance of all contracts of his co-partners, in the same manner as if entered into personally by himself, provided they relate to matters which are within the objects and purposes of the partnership. If the parties to the contract of partnership do not regulate it by express stipulation amongst themselves, the contract, with its duties and obligations, will be implied and enforced by the rules of law applicable to persons in such relative situations; and where the contract does not reach all the duties and obligations, such omissions will be supplied by the same rules of law. Though partners may have entered into a written agreement which specifies the terms on which the joint concern is to be carried on, yet, if there be such a course of dealing as leads to the conclusion that they have agreed to change the terms of the original written agreement, they will be considered to have done so. For instance, if the agreement be that no partner shall draw or accept a bill of exchange in his own name, without the concurrence of all the others, yet, if they afterwards adopt a practice of permitting one of them to draw or accept bills without the concurrence of the others it will be held that they have so far varied the terms of the original agreement. The transactions of partners are always to be looked to in order to determine between them, even against the written articles, what clauses in those articles will not bind them. It is impossible to state all the varieties of stipulation which are introduced into partnership articles; it will be sufficient to repeat that within the limits before laid down, the parties may enter into such stipulations as they please.

One partner may maintain an action of covenant against his co-partner, whether the covenant be for the payment of money or the performance of any act for commencing or establishing the partnership, or for the performance of any of the articles after the partnership has commenced; and if adequate compensation for the breach cannot be had at law, a court of equity will enforce a specific performance of the covenant itself. Courts of law do not allow actions of debt by one partner against another for money due upon simple contract, as for money laid out by one partner for the purposes of the partnership. The partner who is aggrieved must therefore enforce his remedy by action of account, or by an application to a court of equity, by filing a bill for an account and a dissolution of the partnership. A partner cannot maintain an action of debt against his co-partner for work and labour performed, or money expended on account of the partnership; if therefore he has a claim upon his co-partner for a sum of money due on account of the partnership, but not constituting the balance of a separate account, or a general balance of all accounts, his only mode of recovering the amount is by an action of account, or by a bill in a court of equity praying for an account, and usually also for a dissolution. If it turn out that an undertaking is impracticable, as if a machine, for the working of which the partnership was entered into, will not answer the purposes intended, and so the object of the parties is frustrated, or if either party commit fraud, or gross acts of carelessness or waste in the administration of the partnership, the party aggrieved has a right to a dissolution, and the same will be decreed in equity. A partner is also entitled to an account of the partnership assets against his co-partner, but it was formerly held that he could not have it pending the partnership. If therefore he filed his bill for an account, it was also necessary to pray for a dissolution. It is now considered that a partner may have such an account on stating a proper case, without asking for a dissolution; but considering the circumstances under which a partner files a bill for an account of partnership dealings, it will seldom happen that it will be his interest not to pray for a dissolution of the partnership. Where one partner has committed such breaches of duty as would warrant a decree for a dissolution, a court of equity will interfere summarily by injunction: as where one partner has involved the partnership in debt, or has himself become insolvent, the court will restrain him from drawing, accepting, or indorsing bills in the name of the firm, from receiving the partnership debts, and from continuing to carry on the business by entering into new contracts. It will also restrain an action brought by one partner against his co-partner on a separate and private account, upon payment by the latter of the money into court. So it will restrain the application of the partnership property to a use not warranted by the articles; or an execution against the partnership property for the separate debt of one partner. A court of equity will appoint a receiver where one partner excludes another from taking such part in the concern as he is entitled to take, and will do this even with a view to the continuation of the co-partnership, if it is for the benefit of the complaining partner, although such a step is usually taken with a view to a dissolution and winding up of the partnership affairs. Whether the party applying for a receiver wish a continuance or dissolution of the partnership, he must make out such a case to induce the court to interfere, as would authorise a decree for a dissolution.

Generally speaking one partner has an implied authority to bind the firm by contracts relating to the partnership, and he can do this by mere verbal or written agreements, or by negotiable securities such as bills of exchange and promissory notes. One partner may pledge the credit of the firm to any amount; but there are some exceptions to this rule. A dormant partner is in all cases liable for the contracts of the firm during the time that he is actually a partner; and a nominal partner is in the same manner liable during the time that he holds himself out to the world as a partner. Partners can make no arrangements among themselves which will limit or prevent their ordinary responsibilities to third parties. The power of one partner, above alluded to, to bind his co-partner, is implied in law, no express authority from the latter being necessary for that purpose; and in the case of bills of exchange, it exists by custom which has been judicially recognised. One partner may give a guarantee for himself and his partners, and the firm will be bound by it, if it be made in a matter relating to the partnership. The act and assurance of one partner, made with reference to business transacted by the firm, will bind all the partners. A partner will also be liable in respect of a fraud committed by his co-partner, if committed in the capacity of partner, in contracts relating to the co-partnership, made with innocent third persons. Thus, if a partner purchase goods such as are used in the business, and fraudulently convert them to his own use, the innocent partner, provided there be no collusion between the seller and the buyer, is liable for the price of the articles. But partners are not liable for the wrongs of each other, excepting where one partner acts as the servant of the rest, in which case the whole of the partners are liable to the consequences of any wrong he may do; and they may be proceeded against altogether, or one may be sued alone for the whole of the damage done. One partner has no implied authority to bind his co-partner by deed, yet if he execute a deed on behalf of the firm, in the presence of and with the consent of his co-partners, it will bind the firm. It seems that a release by one of several partners to a debtor of the firm binds the firm; but if such release be fraudulent, it will be set aside by a court of equity; and even a court of law will interfere to prevent a fraudulent release from being pleaded.

Where no time is mentioned in the deed of partnership for its commencement, the liabilities of the firm will commence from the date of the deed; but in adventures, unless the parties have previously held themselves out as partners, the liabilities commence from the time fixed by the contract. An in-coming partner is not liable for debts contracted before he joined the firm, but if he pay any of the old debts or interest upon them, or does other special acts, he may render himself liable in equity. In an adventure an in-coming partner is not liable for the price of the goods. When an infant partner comes of age, and does not disaffirm the partnership, if he wish to avoid being liable for the future debts, he must give the creditors notice of his disaffirmance: but for the past contracts he cannot be sued unless he promise to pay, or his ratification of the debts contracted in infancy be made in writing. On the retirement of an ostensible partner, notice of his retirement must be given, or he will be liable to the creditors of the continuing firm for subsequent contracts made by them, and such notice is usually given in the Gazette; but notice in the Gazette will not bind creditors who are not shown to have seen the notice. Third persons have a claim against a dormant partner for contracts entered into by the firm while he was a partner. This claim is founded on such dormant partner being actually a partner: and therefore it is unnecessary, on the dissolution of a partnership between an ostensible and a dormant partner, to give notice of the dissolution to the creditors, in order to protect the latter from subsequent contracts; for when the dormant partner has ceased to be a partner, he is relieved from all future liability.

It is collected from the majority of cases that a partnership contract is joint (not joint and several) both at law and in equity. Upon the death of a partner therefore the legal remedy against him in respect to the joint contract is extinguished, and the creditors can maintain an action against the surviving partners only. But the rule of equity as applicable to partners with respect to third parties was considered to be that the joint debts should be satisfied out of the joint estate; if that were insufficient, then subject to the claims of their separate creditors out of their separate estates proportionally; and if any of them were insolvent, then out of the remaining separate estates proportionally. But the case of Devaynes *v.* Noble (1 Mer., 529), since affirmed on appeal by lord Brougham (2 R & M. 495), has established the principle that a partnership contract is several as well as joint; and that a partnership creditor may have recourse for full payment to the estate of a deceased partner. And the same judge (Sir W. Grant) who decided that case, declared that a partnership debt has been treated in equity as the several debt of each partner, though at law it is only the joint debt of all.

It has been before said that notice of the decease of a partner to the creditors of the firm is not necessary to free his estate from future liability; but it is otherwise if one of the surviving partners be executor of the deceased. A deceased partner sometimes directs his executors to continue the trade; in that case his estate will be liable to the extent to which he directs his assets to be employed. If the executor exceed that limit, he becomes personally responsible.

In actions by partners, all the partners may, and all ostensible partners must, join as plaintiffs, unless the contract upon which the action is brought be in writing under seal, when only those partners who are included can sue thereon. But if a contract not under seal be made by some, for the benefit of themselves and others, those for whose benefit it is made, as well as those whose names appear on the contract, may sue. Parties to a legal partnership cannot recover upon an illegal contract, although its illegality, at the time it was made, were only known to one of the members of the firm. Persons who may legally be partners in foreign countries, as husband and wife, cannot sue here as partners, for by the law of England husband and wife are not permitted to sue as partners. On the other hand, partners trading abroad in such a manner as to make a partnership here, may sue as partners for consignments sent to this country, though they cannot sue as partners at the place of trading by reason of the particular law of that place. The construction of contracts is governed by the laws of the country in which they are made; but remedies must be pursued by the means pointed out by the law of the country whose tribunals are appealed to. The laws of the country where the contract was made can only have a reference to the nature of the contract, not to the mode of enforcing it. If partners have occasion to prefer an indictment relating to the partnership property, such property may be stated in the indictment as belonging to one of them by name, and to another or others, as the case may be. But though it is not necessary to name all the partners, yet where there are other partners, that fact should appear in the indictment, or the prisoner must be acquitted.

A whole firm may become bankrupt, or some or one only of the partners may become so, whilst the remaining members may be solvent; but those only of the partners who have committed acts of bankruptcy are to be deemed bankrupts; and to constitute two or more bankrupts under a single adjudication, there must be evidence of joint trading. Upon the bankruptcy, the whole of the bankrupt's property vests absolutely in the assignees, who have the same remedy by action for the recovery of the debts due to the bankrupt, and for the redress of all civil injuries with respect to the property passing to them under the adjudication, as the bankrupt would have had if none had been made. Accordingly, when the bankruptcy is separate, the solvent partners join with the assignees in an action for the recovery of the joint debts. On the bankruptcy of one partner, the solvent partners become tenants in common with the assignees of all the partnership effects. Upon the bankruptcy of one partner, under a separate adjudication made against him, his assignees take all his separate property and all his interest in the joint property; and if a joint adjudication issue against all, the assignees take all the joint property, and all the separate property of each individual partner. Joint estate is that in which the partners are jointly interested for the purposes of the partnership at the time of the bankruptcy. Separate estate is that in which the partners are each separately interested at that time. Joint debts are those for which an action, if brought, must be brought against all the partners constituting the firm; in all cases therefore when a partner becomes liable for a debt contracted by his co-partners, a joint debt is created, and the creditor is a joint creditor of the firm. Separate debts are those for which the creditor can have his remedy at law against that partner only who contracted them.

The rules relating to joint-stock companies, banks and mining adventures not regulated by charters of incorporation or special custom were formerly exactly the same as those of any other kind of partnerships. But recent legislation has considerably modified the position of these associations, by introducing under certain restrictions, the principle of *limited liability*. The stat. 19 & 20 Vict. c. 47 (1856) amended by some subsequent acts, now regulates most joint-stock companies. The stat. 20 & 21 Vict. c. 49 (1857), and 21 & 22 Vict. c. 91 (1858) apply to joint-stock banking companies, the latter statute enabling these bodies to avail themselves if they please of the principle of limited liability. For more detailed information the reader is referred to the article JOINT-STOCK COMPANIES.

A bill for consolidating the enactments on this subject was introduced in the late session of parliament (1860), but did not pass into law.

The legal condition of part-owners of ships is considered under SHIP.

The chief rules of Roman law as to partnership may be collected from Gaius, iii. 148-154; 'Dig.,' xvii., tit. 2; Cicero, 'Pro Publio Quintio.'

(Collyer 'On Partnership,' and Blackst. Comm., v. ii., p. 526, Mr. Kerr's edition.)

PARTY WALLS. [BUILDING ACTS.]

PARVISE (*parvis*, in French), an old term for an open area or porch before the principal entrance of a church. It appears to have been used only or chiefly with reference to a cathedral or other large church. The older French writers term the pronaos of the Parthenon, or the outer circuit of the temple at Jerusalem, a parvis. By modern English writers on Gothic architecture, the room sometimes seen over a church porch is called a parvise. These rooms, which are often of later date than the porches, are supposed to have served as the private oratories of chantry priests, or as some think, to have been occupied by anchorites or recluses. Examples of these parvises occur at Fotheringhay, Northamptonshire; Sherborne, Dorsetshire; Harrow-on-the-Hill, Middlesex, &c.

PARVOLINE ($C_{15}H_{13}N$). An organic alkaloid found in Dorsetshire shale-tar. It is isomeric with cumidine.

PA'SHA or BASHA, a Turkish appellation for a man in high command, such as the great officers of the Porte, the governors of provinces, and the high admiral, who is called Capitan Pasha. The provinces administered by Pashas are called Pashaliks. The Turks often write the word Pashah with an h at the end, as if it were a contraction or corruption of the Persian word Padishah, which is a compound of Pad, "a guardian," and Shah, "a king," and which is the title assumed by the Ottoman Sultan, the king of Persia, the Mogul, and other great Eastern potentates. (Herbelot, 'Bibliothèque Orientale.') Some derive Pasha from the Persian Paï Shah, "the foot of the king," because those officers tread in the steps of the sovereign and stand in his place. ('Continuation' to D'Herbelot, vol. iv., 4to. edition, 1779.)

PASQUIN, the name given to a mutilated ancient statue which stood at the corner of the palace Santobuono, in a small open place in the city of Rome, near the Piazza Navona. It represents a warrior in the attitude of defence. The subject of the statue is not known. Pasquino was the name of a tailor who lived in that neighbourhood "many years since," says Parisio, in his 'Antiquities of Rome,' published A.D. 1600. The shop of Pasquino was a sort of place of meeting for the people of the district, who came there to tell or hear the news of the day, as is still the custom in the apothecaries' shops in the provincial towns of Italy. The tailor was a facetious man, and his witty sayings were styled "Pasquinate," which afterwards became a common appellation for humourous epigrams and sarcastic lampoons, a kind of composition for which the modern Romans are noted. These lampoons, which often attacked people in high stations and the government itself, were fixed in the night on or near the statue already mentioned; and thus the statue itself came to be called Pasquino, as being the representative of the witty tailor of that name. Collections of these epigrams have been made, and some of them are very witty, though often scurrilous and coarse.

PASSENGERS. [SHIPS.]

PASSIVE VOICE. [MIDDLE VOICE.]

PASSOVER (פסח, *a passing over*, or *sparing*, *πάσχα*), also called the feast of unleavened bread, one of the three great annual festivals of the Jews, was established to commemorate God's passing over the houses of the Israelites in Egypt when he slew the first-born of the Egyptians (Exod. xii. 27). It was first observed in Egypt on the night before the Exodus. It began on the evening after the 14th day of the month Abib, or Nisan, which was the first month of the sacred year, and lasted seven days, the first and last of which were observed as especially holy by abstinence from all labour, and by a convocation of the people for worship. After the settlement of the Israelites in Palestine, it was incumbent on all their males to go up to the Temple to keep this feast. The following were the ceremonies observed in its celebration:—A lamb, or kid, a male of the first year, without blemish, was selected by each household (or if the households were small, by two conjointly) on the 10th day of the month, and it was kept till the 14th day of the month, when it was killed in the evening (literally, "between the two evenings," an expression which is variously interpreted), and roasted, and eaten with unleavened bread and bitter herbs. None of it was to be left till the next day: all that was not eaten was to be burnt. They were to eat it in haste, standing, with their loins girt, their shoes on their feet, and their staves in their hands, as those prepared for a journey. None, whether Israelites or strangers, were to partake of it unless they had been circumcised. Not a bone of the paschal lamb was to be broken, and all of it was to be eaten in the same house. When the lamb was killed, its blood was sprinkled with a bunch of hyssop on the lintel and door-posts of the houses, which was intended, in the original institution of the feast, as a sign to distinguish the houses of the Israelites from those of the Egyptians; and no one was to go out of doors till the morning.

During the seven days for which the feast lasted none but unleavened bread was to be eaten, on penalty of being cut off from the people. Sacrifices were appointed to be offered on each of the seven days (Numb. xxviii. 17-25). On the second day of the feast a sheaf of corn was to be brought, as the first-fruits of the harvest, and the priest was to wave it before the Lord. (Levit. xxiii. 10; Joseph., 'Ant.,' iii. 10, 5).

The word passover is used not only for the feast, but also repeatedly for the paschal lamb itself.

This institution was typical of the death of Christ for the salvation of his people (1 Cor. v. 7); and it was at the passover that the Lord's supper was instituted.

(Winer's *Biblisches Realwörterbuch*, under 'Pascha;' Lightfoot's *Temple Service*, c. 12.)

PASSPORT, a printed permission signed by the secretary of state of the home department of a country, or some other constituted authority, which allows a subject of that country to leave it and go abroad. When he has obtained this, the bearer must have his passport signed by the minister or agent of the state to which he intends to proceed. A foreigner who wishes to leave a country where he has been residing, generally obtains his passport from the minister or agent or consul of his own state. Such a document states the name, surname, age, and profession of the bearer, and serves as a voucher of his character and nation, and entitles him to the protection of the authorities of other countries through which he may pass, and which are at peace with his own. On arriving at the outports or frontier towns of a foreign state, every traveller is obliged to show his passport, which is examined by the proper authorities and signed, or viséd, before he is allowed to proceed on his journey. This ceremony is sometimes repeated at every garrison town which he passes on the road. Even the natives of most European states cannot travel twenty miles through their own country without being furnished with a passport. In Great Britain passports to foreign countries are granted by the secretary of state for Foreign Affairs, by whom also agents are appointed at many of the British ports, who are authorised to grant passports to British subjects.

The system of passports is old. The only civilised countries in which passports are not required are the British Islands and the United States of North America; and the natives of those two countries, accustomed to the freedom of unobstructed locomotion, find the regulations as to passports when they travel on the continent of Europe to be rather irksome. The practice has been defended on the plea that it prevents improper and dangerous persons from introducing or concealing themselves; but numerous instances have proved that persons, however obnoxious, who have money and friends, can evade such restrictions. That every state may admit or refuse admittance to foreigners, as it thinks fit, cannot be questioned; and in times of war especially, some sort of restriction may be required for the safety of the country; but the present system of passports, as enforced in many European states in time of profound peace, is both illiberal and puerile. It is a check upon travellers, to whom it causes much trouble and loss of time, while the advantages supposed to result from it are at least very dubious. It has been compared to spiders' webs, in which flies are caught, but which larger insects or birds easily carry off along with them. In Turkey a passport is called a FIRMAN.

PASTES. [GLASS.]

PA'STORAL (from the Latin *pastor*, a shepherd or herdsman), is the name given to poems which are descriptive of the pursuits of country life, or to dramas in which the characters represent shepherds or other country-people. [BUCOLICS; IDYLL.]

Pastoral letters are circulars addressed by a bishop to his diocesans for purposes of religious instruction or admonition in matters of discipline. This name also is derived from "pastor," the bishop being styled the shepherd of his spiritual flock.

PASTURE, COMMON OF. [COMMONS.]

PASTURE LAND. There are tribes which have no other occupation than that of pasturing domestic animals, and immense tracts of fertile soil are still unappropriated to any definite owner. Where the climate is genial, and the extremes of heat and cold are unknown, cattle are fed all the year round by moving from one place to another. In such a state are some of the wandering tribes of Asia, who have no fixed habitations, but pitch their tents wherever pasture is abundant, and move them to another spot as soon as it is consumed where they are. In civilised countries, where the land is divided and appropriated, such a system cannot exist; though there are still traces of it in this country, as we see in the few remaining waste lands, on which there is a right of common.

The pasturage of cattle is now a part of regular husbandry; the land which affords the herbage for cattle forms part of private possessions, and a rent is paid for its use. This has introduced a new system. Pastures are now fenced and protected, and pains are taken to improve them, so as to maintain many more cattle or sheep than they would in their natural state. We shall not here speak of rich grass lands, in which bullocks and sheep are fatted, and which are commonly called grazing land; nor of artificial pastures, which form portions of arable farms, and have been depastured only to enrich them and make them more fit to produce corn when again submitted to the plough. But we shall consider those tracts of land which, from situation, climate, or other causes, although they are portions of certain estates and the property of individuals, lie nearly in a state of nature, and produce a revenue or profit only according to the number of cattle and sheep which can be reared or maintained in them. Such are the rich pastures on the Jura, the Alps, and Pyrenees, too high and exposed to allow of cultivation or permanent habitation, but producing abundant food for cattle in particular seasons of the year. The Jura and the Alps, which are best known to English travellers, contain very rich pastures for cows, and give a considerable return in butter and cheese. The snow which covers these mountains for a considerable part of the year, protects the herbage; and the moisture which prevails in the summer by the continual passage of clouds, which appear in the form of heavy fogs to those who are enveloped in them, keeps up a luxuriant vegetation of the small Alpine plants which form the richest pasture.

Whenever pastures are hired, the rent is always reckoned, not by the extent of surface, but by the stock which can be maintained upon it. Thus, in Switzerland, the mountain pastures are divided into portions of twenty, forty, or more cows. This mode of reckoning is much fairer than by mere extent of surface. In many places pasturing has been found much more productive than cultivation; and some large proprietors have converted great tracts of land from arable into pasture farms. But this can only be done where the population is very scanty, and where the soil and climate do not tempt men of capital to settle.

Considerable improvements have been made in natural pastures, not only by the raising of banks and stone walls as shelter against the winter's storms, but also by extensive draining and clearing the surface of wild plants and shrubs, which prevent the herbage from springing up, and greatly diminish the feed. On the sides of steep hills, where springs are apt to break out and produce bogs and swamps, drains judiciously made have carried off the water and laid dry the pastures below them; while reservoirs have been constructed in many places to receive the water and to supply the stock in dry weather. On peaty moors the application of lime to the surface has often produced wonderful effects, and made various kinds of clover and grasses spring up which were never seen on the spot before.

Those who are possessed of extensive pastures often look upon them as of too little value to lay out any money in their improvement; and unless when an attempt is made to bring them into regular cultivation, which often fails after a great outlay of money, they are not thought worth any attention. Yet many rough hilly pastures might be doubled and tripled in value merely by clearing the surface, burning coarse grasses, rushes, ferns, and furze; and sowing a few seeds where the ashes have been spread. The additional number of cattle or sheep which can be maintained by this means, would surprise any one who had not had experience of such improvements. The forming of convenient channels for the water to run off is another important object, which can often be effected at a trifling expense; and a loose surface laid dry by this means may be much improved, by merely burning the heath which grows upon it. After the fire has scorched the ground, grasses will spring up spontaneously; and, at a very small expense, a considerable tract of mountain pasture may be converted from the state of a brown heath or moor to that of a fine green sward.

Wherever there are large pastures, proper and suitable buildings made of substantial materials should be erected. The cattle should have numerous sheds for refuge in bad weather, and sheep especially should have protection and shelter. Warmth is in some cases of as much importance as food; and an animal exposed to all the severities of a northern climate requires more food to keep him alive, than when he is kept warm and protected from the immediate influence of cutting winds.

There is another kind of pasture in England on the chalky hills which are called downs, where useful and hardy sheep are reared. Here the exposure is less, and the proximity to the plains gives frequent opportunity of driving the sheep to sheltered situations. The grass on the chalk hills is in general very fine and short, and the quality is very good. The soil is only a few inches deep, and has been robbed for generations by the pasturage of sheep during day, which at night are folded on arable land in their neighbourhood for the sake of the manure which they drop, nevertheless it annually produces a crop of close good pasturage. Attempts are made occasionally to convert some portions of these pastures to tillage: but it is not often an advantageous speculation. A few crops may be obtained at first, but the thin layer of rich earth, which is at its surface, is soon exhausted, and nothing remains but barren chalk. No art can restore the fine turf which had been produced by ages of pasturage.

Very poor pasture on sandy or gravelly loams is of very little value to the proprietor. Where the situation allows of such land being converted into plantations, it will generally be found most advantageous to do so, but if there are means of improving them by ploughing, liming, and manuring, they may often be converted into good arable farms. A great part of Norfolk, which now bears excellent crops of barley, wheat, and clover, was once only poor sandy pasture, where the chief income to the proprietor arose from rabbit warrens. We must not always judge of the capabilities of a soil by the natural grasses which grow upon it, before it has ever been stirred and cultivated. When loamy sand or gravel is left in a hard condensed state, it will bear very little, but when it has been broken up deep, and trenched and improved by lime, marling or claying, and manure, it becomes very useful land. The same may be said of cold wet pastures on a stiff clay, the means of improvement then being drainage, burning, and deep culture. The water checks the roots of the better sort of grasses, and nothing thrives in such pastures except rushes and very coarse aquatic plants; but when they have been carefully drained—when the surface has been pared and burnt, and the ashes spread over the land—a very material improvement takes place, whether it be left unbroken, to produce herbage, or be improved by a course of judicious cultivation, and laid down again to grass in a clean and fertile state; in either case, the pasture, from being of little use, and perhaps dangerous for sheep, which are apt to rot there, becomes sound and good, producing excellent nutritious herbage, and will continue so ever after.

Pastures are seldom improved with manure, which is generally reserved for arable land, or grass land intended to be mown for hay: but if richness is valuable in a pasture, it will well repay the expense of manuring, especially with liquid manure, the drainings of dunghills and the urine of cows and horses, which is collected in a tank when they are kept in stalls. Peat ashes are also very useful, and have a powerful effect in stimulating the vegetation of all the grasses. Saltpetre and nitrate of soda are said to have the same effect. When it is intended to convert land which has been in a state of heath or waste, covered with fern, brambles, ling, and other coarse plants, into good pasture, it is indispensable to begin by a course of arable cultivation; and it is only when the soil has been brought into an improved state by tillage and manuring, and all the roots and seeds of noxious plants have been eradicated, that grass seeds may be sown with any prospect of obtaining a good sward. Most of these soils are poor and sandy, and not very favourable to the growth of good grass. In this case the safest mode of converting the land into pasture is by inoculating it with pieces of sods taken from a good rich pasture. [GRASS LAND.] By this means, and subsequent depasturing with sheep only, very good pastures have been produced on very poor soils; and if in the course of a few years they should degenerate, they may be profitably broken up and cultivated on the convertible system of husbandry, after which they may again be laid down for a certain number of years. Wherever the soil consists of a sandy or gravelly loam, this system is the most advantageous. As to choice of manures, it is found that ammoniacal manures tend to the growth of the grasses, and that phosphate and mineral manures tend to the growth of clover and leguminous plants.

In the richest pastures, such as those of Lincolnshire and other grazing counties, an acre will maintain and fatten an ox of 80 or 90 stone, and sometimes keep several sheep in store order besides. There is a marked difference between land that will fatten an ox, and that which will only rear him. This can scarcely be discovered by simple examination of the land; but is found by experience. The same appearance of grass has more *proof*, as it is called, in one place than another. The bite may be very short, and the pasture appear bare, and yet the value of it may be seen on the ribs of the cattle. Much of the skill of a grazier consists in stocking his pasture to advantage. He should know the power of every portion of it, and stock it so that the grass may not grow faster than it can be cropped by the cattle or sheep, and that the animals may always have the full quantity required. Every animal wants a certain quantity of food to repair the daily waste occasioned by the animal functions. If he has no more, he makes no progress: the more he can convert into flesh and fat beyond this quantity in a given time, the more profitable he will be. Hence the superior qualities of some animals with respect to this point indicate the superiority of their breed, and afford the greatest net profit to the grazier. In the same pasture one beast or sheep will give a reasonable profit, while another may occasion an actual loss. The adaptation of the stock to the nature of the pasture is consequently an object of the greatest importance, and requires much judgment and experience.

PATENA (*Patène*, French), a small circular plate, or salver, employed in the Roman Catholic church in the celebration of the eucharist. From the earliest time the form has scarcely varied. Patenas were frequently made to serve as a cover to the chalice. They were usually of gold, silver, or latten: some which have come down to us are richly ornamented with gems, enamels, or engraved work, and afford exquisite examples of mediæval art.

PATENT. This term is now ordinarily applied to exclusive rights of manufacture granted by royal letters patent under the provisions of the Statute of Monopolies, 21 Jac. I. c. 3, and subsequent statutes. Prior to the Statute of Monopolies it had become not unusual for our Tudor sovereigns to grant by their letters-patent to their favourites and to purchasers, exclusive rights of trading, in derogation of the old common law; and this statute was passed to restrain such abuses, and to settle and determine the circumstances under which encouragement and protection should be afforded to inventors. While therefore the statute commences with a declaration of the illegality of monopolies, it proceeds to except therefrom "all letters patent for the term of fourteen years or under, by which the privilege of sole working or making any new manufactures within this realm, which others at the time of granting the letters-patent shall not use, shall be granted to the true and first inventor thereof; so as they be not contrary to law, nor mischievous to the state, nor to the hurt of trade, nor generally inconvenient;" and within the terms of this exception all valid patents may still be ranged. The grant of a patent is not a thing which the subject can claim as a matter of right; it is the free gift of the crown. The form of the grant is by letters-patent under the great seal, which being the deed of the crown are considered as of public record.

Before applying for a patent for an invention, two considerations are necessary; first, what is entitled to a patent; and next, whether the invention has the requisite conditions.

In the first place, the machine, operation, or substance produced, for which a patent is solicited, must be new to public use, either the original invention of the patentee, or imported by him and first made public here. A patent may be obtained for England, Ireland, or Scotland, although the subject of it may have been publicly known and in use in either or in both of the other two countries.

In the second place, the subject of the invention must be useful to the public, something applicable to the production of a vendible article, this being the construction put upon the words "new manufacture" in the statute of James I. The discovery of a philosophical principle is not considered entitled to such protection: such principle must be applied, and the manner of such application is a fit subject for a patent.

Inventions entitled to patent may be briefly enumerated as follows:—

1. "A new combination of mechanical parts, whereby a new machine is produced, although each of the parts separately be old and well known.

2. "An improvement on any machine whereby such machine is rendered capable of performing better or more beneficially.

3. "When the vendible substance is the thing produced either by chemical or other processes, such as medicines or fabrics.

4. "Where an old substance is improved by some new working, the means of producing the improvement is in most cases patentable."

If the inventor think that the machine, operation, or substance produced comes under any of these enumerations, he may lodge with the Commissioners of Patents for Inventions a petition to the crown for a patent, supported by a declaration in lieu of an oath, that he is the true and first inventor of the manufacture sought to be patented, and that the invention is not in use by any other person to the best of his knowledge and belief. With this petition and declaration must also be lodged an instrument called "the provisional specification," the object of which is to describe the nature of the invention. The applicant is then referred by the commissioners to one of the law officers of the crown, who is at liberty to call any scientific or other person to his aid; and if the law officer shall be satisfied that the provisional specification describes the nature of the invention, and certifies his allowance of the same, the invention may, during six months from the date of the application, be used and published without prejudice to any letters-patent to be afterwards granted; or the applicant may file with the petition and declaration a "complete" in lieu of a "provisional" specification, inserting in the declaration an additional statement, that the instrument particularly describes and ascertains the nature of the invention, and in what manner the same is to be performed; and in this case the applicant has, during the term of six months, the like powers and privileges as under letters-patent during term the invention may be used and published, without prejudice to the subsequent grant of letters-patent.

The next step is for the applicant to give notice at the office of the commissioners of his intention to proceed with his application, which is then advertised by the commissioners; and any person having an interest in opposing the grant of the letters-patent will be at liberty, within a certain period, to lodge particulars in writing of their objection, and to be heard in support of them. The period for objection being expired, the specification and the objections are referred to the law officer, who, if the application seems to him fit, may cause a warrant to be made for the sealing of the letters-patent; which warrant having been sealed by the commissioners, has next to be, under the sanction of the lord chancellor, sealed with the great seal of the United Kingdom, whereby the grant to the applicant, of the exclusive right of using the invention within the United Kingdom, the Channel

Islands, and the Isle of Man, and (if the warrant so direct) within the colonies, for the full term of fourteen years, is completed. A patent right may, however, at the option of the patentee, be limited to a preliminary period of three, and successive periods of four and seven years, in which case the amount of the fees is also distributed. The letters-patent always contain a proviso to the effect that, if the "complete specification" already filed does not particularly describe the nature of the invention and the mode of applying it,—or, supposing no such specification to have been yet filed, then, if the applicant does not within a limited period file such a specification in the Court of Chancery, the grant in the letters-patent contained shall be void. The object of the specification thus required, is to put the public in full possession of the inventor's secret, so that any person may be in a condition to avail himself of it, when the period of exclusive privilege has expired. To prevent this object from being defeated by an evasive or careless description, the proviso is construed with great strictness by the courts of law; and it is held to be infringed, and the letters-patent to be consequently void, whenever the specification is in any part of it materially false or defective. The principal rules on this subject are as follows:—In describing the nature of the invention, the specification must, in the first place, correspond with the title of the patent, for its office is to set forth with more particularity the subject already indicated in the patent itself; and if one thing be claimed by the patent, and another by the specification, the grant is void. It is also an objection to the specification, if it should cover too much; that is, include in its claim of *new* invention anything which in fact has been already known and practised; and therefore if the entire article for which the patent has been taken out comprises some known process in connection with others that are new, the claim should be made in such form as to apply to the latter only, and to disclaim the former; or if the combination of several known things happen to be the only novelty, it is to the combination only that the claim should be pointed. As to the description of the manner of performance or production, the general rule is, that it should be such as to enable workmen or other qualified persons of ordinary skill to make the patent article at the expiration of the term, by simply following the directions given, without resorting to contrivances of their own. In addition to which we may remark, that no circumstance can be safely passed over in this description which is advantageous, whether absolutely essential or not, in the conduct of the process; and that if several methods are stated, the specification will be defective if *either* of them be found to fail in effecting the promised result.

The following are a few instances of patents being lost through defective titles:—

In the case of King *v.* Metcalfe (2 Starkie, N.P.C., 249), the subject of the patent was a hair-brush, in which the hairs were of unequal length: in the title it was described as a "tapering brush," which was considered as intended to mislead the public, as not being a description of the subject of the patent, and it was annulled accordingly. In Cochrane *v.* Smethurst (K. B., 1 Starkie, 205), the patent was for a certain lamp, but the title called it an "Improved Method of Lighting Cities, Towns, and Villages." The patent in this case was held to be void, as the specification only described a new lamp, and not an "improved method of lighting" at all; and it was also objected, that as it was equally applicable to lighthouses, harbours, shipping, &c., the title was otherwise imperfect. If the title had been for an "Improved Lamp" or an "Improvement on Lamps," the patent would have been valid. In the case of King *v.* Wheeler, the patent set forth in its title a "New and Improved Mode of Drying and Preparing Malt," whereas the specification described a method of re-burning malt which had already been made, so as to produce a colouring matter for beer and other liquors. Now it is evident that if any one had intended to take out a patent for producing colouring matter, he would never have collected from this title that the patent was likely to interfere with his invention. In the case of Bloxam *v.* Elsee (6 Barn. & Cress., 169 and 178), the title of a patent which came in question was "A Machine for making Paper in Single Sheets, without Seam or Joining, from 1 to 12 feet and upwards in width, and from 1 to 45 feet and upwards in length." The specification, however, described a machine only capable of producing paper of one width or to a certain width. Now if an inventor who thought of taking a patent for a machine to make paper of a greater width than 12 feet had looked at the title only of this patent, he would have supposed that such a patent already existed; but if he had inspected the specification, he would have found that it did not bear out the title, as the machine therein described was not capable of making paper of a width greater than 12 feet. The patent then was invalid, as the title comprised more than the specification. This is the most common error that patentees fall into. Jessop's case, cited during the trial of Boulton and Watt against Bull, in 1795, by Mr. Justice Buller, is another instance. A patent was taken out for a "New Watch," whereas the specification only described a particular movement in a watch, which was the real invention, and the patent was therefore void.

Patentees sometimes render their patents invalid by claiming too much; thus, after describing one substance or process which will answer a certain purpose, they often conclude by some such expression as, "or any other fit and proper means." The following is an instance in which a patent was set aside by such an expression. In specifying a machine for drying paper by passing it against heated rollers by means of an endless fabric, the inventor, after describing one sort of fabric, the only one in fact which he used, went on to say that any other fit and proper material might be used. Now if he used any other means of effecting his object, such means should have been distinctly described. This alone rendered his specification incomplete; but, besides this, it was proved that no other fabric would answer the purpose, or rather that no other was known, and the patent was annulled accordingly.

The patentee may describe his invention just as he pleases, and he may illustrate such description by drawings or not; but he should be careful to use words in their most common acceptation, or if some technical use should have perverted their meaning, he should make it appear distinctly that he intends them to be taken in such perverted sense.

An honest and valid title may be stated in a few words to be a description of the precise object of the invention in the most simple language.

A patent right is *assignable;* and the assignment of it must be in writing, under hand and seal. It is of course personal property, and as such passes by will. The patentee may, without alienation of his entire interest, grant deeds of *licence* to other persons to manufacture the article.

In favour of patentees who have not reaped the full benefit of their inventions, the legislature has frequently interfered, by passing private Acts of Parliament to secure them the continuance of their privileges for a further term of years, in addition to that first limited by the letters-patent. But a less costly mode of relief is now provided; and where the invention is meritorious, and the parties interested have done all in their power to bring it out and to turn it to advantage, but owing to circumstances beyond their control they have been unable to obtain an adequate remuneration, they may now apply *by petition* to Her Majesty in council for a prolongation of the existing term; and if, upon consideration of the whole matter, and after hearing any party who may choose to enter a "caveat," the judicial committee of the privy council shall report in favour of the application, Her Majesty is empowered to grant to such patentee (or to his assigns, or to both conjointly, as the case may be) new letters-patent, for any term not exceeding fourteen years after the expiration of the first.

If a patent right be infringed the inventor has his remedy, by action, to recover damages for the injury sustained; and may in such action, by application to the superior court in which it is brought, obtain an order for restraining the wrong-doer from the further use of the invention, and compelling him to account for the profits which he may have already derived from a sale of the article; an order which may also be in some cases obtained without resorting to an action, by application to the Court of Chancery. Penalties, moreover, are imposed upon persons who without licence use the name, stamp, or mark of a patentee. An action or suit for infringement of patent may be successfully resisted, either on the ground that no infringement has in fact taken place, or that the patent is void; and such invalidity may be established either by showing that the article was not a fit subject for a patent, or that the patentee was not the first inventor, or that the specification was insufficient. Nor is this the only method of defeating claims founded on an illegal grant of patent right; for whether there be any complaint of infringement or not, it is competent to the Queen (or to any subject of the realm in the Queen's name, by leave of the attorney-general) to institute a proceeding called *scire facias,* for the formal impeachment of the patent; upon which, if the patent be found open to any of the objections above enumerated, or to any other sufficient legal exception, it will be cancelled.

For the protection of patentees, several other provisions, of great importance have been enacted. First, in the case where, after a patent has been granted to a person believing himself to be the first inventor, it is discovered that some other person had in fact preceded him in the use of the invention, though the article was, at the time of the grant, not generally known to the public, the patentee or his assigns may petition Her Majesty in council for a new grant, or a confirmation of the existing one; and if the judicial committee of the privy council, upon investigation of the case, report in his favour, such petition may be granted. Again, if any error be discovered in the title or specification, the patentee or his assigns may rectify it for the future by filing in the proper office in chancery a *disclaimer* of any part of the title or specification, or a memorandum of any alteration therein that does not operate as an extension of the patent right.

The statutes relating to patents are the Statute of Monopolies above mentioned; and of more recent date, the 5 & 6 Will. IV., c. 83; 2 & 3 Vict., c. 67; 7 & 8 Vict., c. 69; 15 & 16 Vict., c. 83 (which introduced very great and very beneficial alterations in the proceedings relating to patents, and is styled "The Patent Law Amendment Act, 1852"); the 16 & 17 Vict., cc. 5 and 115; and lastly, the 22 Vict. c. 13, which provides for keeping secret in certain cases the particulars of inventions of instruments and munitions of war.

The fees payable upon the grant of a patent for the full term of fourteen years are about 175*l*.

See, upon the law of patents, Stephen's 'Commentaries,' vol. ii. p. 25 *et seq.*, where the statutory and case law is completely and succinctly collected.

See, upon the subject generally, and also upon "the Patent Office Museum and Library," a very valuable article in the 'Companion to the British Almanac,' for 1860.

PATENT. [Patterns.]

PATENT, LETTERS. [Letters-Patent.]

PATERA, an open vessel, approaching to the form of a cup but flatter, used by the Romans in their sacrifices, in which they received the blood of the victims, and with which they made libations. Some pateræ have a single handle. The word contains the same root as *pateo*: "Patera ut et ipsum nomen indicio est, poculum planum ac patens est." (Macrobius, 'Saturn.' v. 21.) Flat open vessels used by the Romans at their meals were called pateræ, whence perhaps pateræ came to be employed in offerings to the gods. Virgil, in several passages of the 'Æneid,' alludes to the uses of the patera. (Lib., vi. 248, iv. 60, vii. 133.)

On medals the patera is represented in the hands of several of the deities (Rasche, 'Lexicon Universalis Rei Numariæ,' tom. iii., part. ii., pp. 626, 627), and frequently in the hands of princes, to mark the sacerdotal authority as joined with regal power. The patera was of gold, silver, bronze, marble, glass, or earthenware. Such as had served for libations of wine or any other liquor at a funeral were usually deposited with the ashes of the deceased. Pateræ were often ornamented with engraved or embossed designs, and sometimes with gems. They appear to have been called by their prevalent mode of ornamentation, fern and ivy being the most usual, as patera filicata, patera hederata. The British Museum contains many fine specimens of fictile as well as bronze pateræ; also several sculptured marble votive pateræ, with figures of Pan, Silenus, Cupid, &c. Patella (that is, paterula) is the diminutive of patera.

The term *patera* is applied to a circular flat or concave ornament in classical architecture. It is also used for ornaments of a similar form in Italian and Gothic architecture.

PATERNITY. [Bastard.]

PATHOLOGY (from πάθος, 'disease,' and λόγος, 'a discourse') is the science of diseases, and especially of those which affect men and animals which are the subjects of medical treatment.

For the perfect knowledge of the nature of a disease, the first circumstance to be determined is its cause; and this is commonly regarded as twofold. The predisposing cause or condition (for the term cause cannot fairly be used in this sense) is that state of any individual which renders him peculiarly liable to the attack of any or of some particular disease, of which another person or he himself at another time might be in little danger. Of these predisposing conditions the most important is hereditary disposition, by which an individual being constructed with the same peculiarities of internal and of external form and composition, which one or both of his parents possessed, is liable to the same diseases as they were. Such are the peculiarities of temperament or constitution with which each individual is born, and by which he is through life disposed to a peculiar character of disease; and such also are the special hereditary dispositions to scrofula, gout, insanity, some forms of asthma, and probably many more diseases. Other predisposing conditions are the peculiarities of constitution which are acquired in the course of life by particular modes of living. Each individual is adapted by habit and other circumstances to the conditions of climate, &c. in which he is placed, and is peculiarly liable to be affected by changes of these external conditions. A person of effeminate habits living carefully secluded from all excitants of diseases, is much more liable to be affected by exposure to any of them than one whose frame by a hardy course of life is rendered comparatively invulnerable to all. Any means by which the strength of the body is reduced render it more liable to diseases of all kinds, and hence our idea of bodily strength is drawn not more from the muscular power of the individual than from his immunity from the effects of those circumstances which in others excite disease. There are also local peculiarities of individual organs of the body which render them especially liable to disease; such are the state bordering upon disease which is brought on by constant over-excitement of any organ; the condition of an organ which has once been affected with a disease, and which is commonly thenceforward particularly liable to a repetition of it; the state of the organs which at different periods of life renders one more than another liable to disease, so that the same excitant will be most likely to produce in the child an affection of the head, in the youth a disease of the chest, and in the adult or old person some disorder of the abdominal organs.

Any of these predispositions however may exist throughout life without the occurrence of actual disease; in order to produce disease, some more immediate or exciting cause is necessary. This excitant must be the more powerful the less the predisposition: but under whatever circumstances disease is produced, the predisposing condition of the patient may be expected to confer upon it a corresponding peculiarity of character. The exciting causes of diseases are any changes of a certain extent in the conditions of the external circumstances in which man is placed. For example, a certain range of external temperature, a certain constitution of the atmosphere, a certain supply of pure food and drink, a certain amount of mental and bodily exertion, are circumstances essential to health, and alterations in any of them may produce disease, of which the nature and the seat will be determined in part by the predisposition of each individual, and in part by the peculiar mode of action of the excitant. Thus, after the same exciting cause (for example, exposure to cold and damp), one person may have rheumatism, another pleurisy, a third ophthalmia, and a fourth may escape altogether unharmed. But there are other excitants of disease which prevail over all predisposition, and produce a certain character of disease, which the constitution of the patient can only slightly modify; such are the materials of all contagious and epidemic disorders, as influenza, small-pox, measles, &c., which produce in all whom they attack a similar affection. Many persons however escape from the effects of these excitants, and by long exposure become inured to them; hence the diseases of peculiar climates (endemics) affect foreigners much more than natives; but even in those persons in whom they do not produce disease, these conditions, which are excitants of disease in others, modify the characters of diseases that occur from any other source; and hence in the course of an epidemic all diseases have a tendency to assume some of the characters of that which is prevalent. Other excitants of disease, still more universal in their influence and more constant in their consequences, are all things which act immediately on the composition or construction of the body or of the blood, such as mechanical and chemical injuries, including poisons of all kinds.

The nature of a disease being determined by the condition of the individual and the exciting cause to which he is exposed, the next division of pathology is the study of the symptoms or signs by which the progress of a disease is marked, and by which in practice its nature is to be determined. Of these signs of disease, many are expressive of the altered condition of the part chiefly affected, as pain in a wound, or a local inflammation, coughing in a disease of the lungs, sickness in a disorder of the stomach: but a greater number are the expressions of an affection of other organs, which suffer in association with those primarily diseased; such are pain in the head when the digestion is disordered, coughing in diseases of the liver, sickness after violent blows on the head. Sometimes these secondary symptoms completely mask those immediately resulting from the primary disease; as when in a disease of the hip the chief pain is felt in the knee, or in hysteria any organ may appear disordered except that which actually is. These secondary symptoms are ascribed to what is called sympathy, an unsatisfactory expression indicating only the coincidence and probable connection of symptoms of disease in two organs, of which one only is supposed to be materially affected. Entire ignorance must be confessed of the nature and origin of many of these sympathetic or indirect symptoms of disease; as, for example, of the fever consequent on local injuries or acute local diseases, and of the hectic fever of many chronic affections; but it is probable that all sympathies will in time be found to depend either on some communication of excitement from one nerve to another through the medium of the spinal chord or brain, as in the reflex actions [Nervous system, in Nat. Hist. Div.], or on some change in the blood which affects both organs at once, or which, originating in the disease of one disturbs the functions of the other, or of the whole body.

Whether directly or indirectly produced, all the symptoms of disease are only the perversions of the natural functions of the part affected, or appreciable changes in its structure; their value and meaning therefore can only be determined by a comparison with the same functions and structure in health; in other words, this, like all other parts of pathology, cannot be rightly studied without a constant reference to physiology. It is believed that an organ may be only functionally deranged; that is, that its several functions may be performed in a very unhealthy manner, without the existence of any material change in its structure and composition. These are called functional symptoms, but their number is probably much less than is generally believed, and it is most likely that they are limited to the variations to which the organs are subject by the changes in the mode and measure of the influence of the nerves upon them. For all other symptoms we must assume the existence of a substantial change in the part affected, or in the materials on which it has to act, although in many cases these changes are fugacious or inappreciable by our senses.

For a due performance of all the functions of organic life [Vitality, in Nat. Hist. Div.], a healthy structure of each organ, and a healthy composition of the blood, on which they all act and all depend for their own maintenance, are alike necessary; a deviation from health in either will therefore produce the symptoms of disease; a conclusion in which the long continued disputes of the humoral pathologists, who ascribed all disease to the blood, and the solidists, who held all to depend on changes of structure, have at length merged. To these two kinds of alterations, and to perturbations in the distribution of the nervous influence, it is probable that the signs of all diseases may be referred; but from the peculiar and complicated nature of the animal body, and the universal connection between all its organs, no one of these changes can long continue without producing the others; and hence in diseases of any degree of severity the symptoms are commonly a mixture of the disorders of all the functions of the body, and the disorder of each is modified by the changes in all those circumstances on which its healthy state depended, as the condition of the blood, of the nervous influence, &c. Neither are the symptoms in any case constant phenomena; for the influences of all external circumstances upon a diseased body are very different from those which they exert upon the healthy body, and many things which were necessary to health are supporters of disease, as the usual amount of food, of bodily and mental exertion, &c.; so that exclusion from them becomes necessary, and this again further modifies the performance of the disordered functions.

The history of a disease is completed by the process of natural recovery or by the observation of the changes in the structure of the body which it produces. The influence of remedies cannot justly be considered as a branch of pathology; though most important for their utility, still, in their relations to the natural history of a disease, medicines can only be regarded as interfering circumstances, or as the means of experiments for the determination of the relation of the diseased body to particular agents, by which the nature of the disorder affecting it may be sometimes ascertained.

The recovery from disease is an example of the exercise of that power by which the body can make unusual efforts to prevent its own destruction: this has been called the vis medicatrix naturæ, or curative force of nature. It is exerted in many cases in which disease cannot be said to exist, but where rather there is an exaggeration of health; as, for example, when a muscle subjected to unusual exertion and an unusually great amount of waste not only repairs its loss, but actually becomes larger and stronger, so that it can bear the same amount of constant waste better than at first; or as when a person is exposed for a time to cold in bathing, the speedy consequence is an increased warmth of the surface. The term reaction is applied to phenomena of this kind, and it may be said that reaction takes place whenever any injurious influence is applied to the body. In simple cases the reaction effects at once a restoration to health, as in the instances above mentioned; in others the reaction is itself the most prominent feature of the disease, as in fever and inflammation.

The recovery from disease is rarely perfect. Although no visible change may be left behind, yet the part diseased is commonly for ever after weak, that is, more than usually liable to the same or to some other disease. It is probable that this liability is owing to some morbid change in the structure of the part inappreciable by our present means of examination; in more distinct cases, when any part has been severely diseased, we never see a perfect restoration of its healthy structure and form. Even in those tissues that are most easily repaired, there is not an actual reproduction of the injured structure.

The period occupied in the progress of a disease to recovery or death is the basis of the chief division of acute and chronic diseases. The severity of the symptoms may in both cases be the same; but in general those of chronic cases are less prominent than those of acute cases.

When the disease terminates fatally, or when death takes place from any other cause at a distant period from its occurrence, we obtain perhaps the most valuable because the most certain part of pathological knowledge, that of the material effects which the morbid process has produced. This, the study of morbid anatomy, is often specially called pathology. By the examination of the altered parts and a comparison of the changes of structure which they present with those which are known by observation of external diseases or by experiment to result from certain leading morbid processes, as inflammation, &c., we are enabled to determine the nature of that which had existed beyond the limit of our senses, and thus to appreciate correctly the meaning of the several symptoms which had marked its progress during life, and the powers and modes of action of the circumstances to which it owes it origin. The practical value of such knowledge is the power which it affords of determining during life the nature of each disease, and the appropriate remedy for each.

PA'TINA, a shallow bowl, or basin, of earthenware, used by the Greeks and Romans for various domestic purposes, but chiefly in cooking or in serving at the table. Patinæ were sometimes made of bronze or silver. The eucharistic patena of the Romish Church is no doubt derived from it, though it differs in form. [PATENA.]

PA'TINA, a word used by archæologists to express the polished rust by which ancient remains of copper, bronze, or brass are covered when laying in particular soils. This rust tends to the preservation of the object, and enhances its value, and appears to have been prized by the Greeks and Romans. The variety of tints of red, green, blue, brown, purple, olive. and yellow is owing to the combustion of oxygen, carbonic acid, and other gases with the alloys of which the metal is composed. [NUMISMATICS.]

PATRIARCH (*πατριάρχης*, the head of a family), a title given to the heads of families in the early history of the human race, and more particularly to the ancestors of the people of Israel down to the time of Moses, and especially applied to the twelve sons of Jacob, as the ancestors of the twelve tribes of Israel.

There is a book in existence entitled 'The Testaments of the Twelve Patriarchs, the Sons of Jacob,' containing what profess to be the dying admonitions of the patriarchs to their children, and their predictions of the future fortunes of their descendants. This work has been published in Greek by Grabe, from manuscripts in the universities of Oxford and Cambridge ('Spicileg. Patr.,' tom. i.), and again by Fabricius ('Cod. Pseudepigr. Vet. Test.,' 1713); it was translated into Latin by Grostête, bishop of Lincoln (8vo, Haganoe, 1532), into French by Francis Mace, and into English by Whiston, in 'A Collection of Records belonging to the Old and New Testament,' London, 1727-8. Whiston has a dissertation to prove the authenticity of the work, but his arguments are neither worth repeating nor refuting. It is undoubtedly spurious. There is no evidence to prove that it ever existed in Hebrew, and the earliest reference to it by any ancient writer is one by Origen, who expressly asserts that it formed no part of the canon. Lardner has a very good notice of the work. ('Credibility,' pt. ii., ch. xxix., s. 3.)

The author of this book was probably a converted Jew, though not, as Cave supposed, a Judaising Christian. It seems to have been written about the end of the 2nd century.

Patriarch, in Church history, was also the ecclesiastical chief of a diocese, which included several provinces. It is not known at what time this title was introduced into the Church, but before the 4th century the bishops of Rome, Antioch, and Alexandria, had obtained a degree of pre-eminence over the other bishops. In the time of Constantine the Great the bishop of Constantinople was made to rank with the three just mentioned; and either then or not long after the title of patriarch was given to these four prelates. The number of these dignitaries was increased in the 5th century. The patriarch of Constantinople reduced under his jurisdiction those of Antioch and Alexandria, and obtained the title of "Universal Patriarch." The bishop of Rome was called "Prince of the Patriarchs." The struggle between the patriarchs of Rome and Constantinople for supremacy was the chief cause of the separation between the Eastern and Western Churches.

The powers of the patriarchs are thus described by Mosheim:—"They alone consecrated the bishops who lived in the provinces that belonged to their jurisdiction. They assembled yearly in council the clergy of their respective districts, in order to regulate the affairs of the Church. The cognisance of all important causes, and the determination of the more weighty controversies, were referred to the patriarch of the province where they arose. They also pronounced a decisive judgment in those cases where accusations were brought against bishops. And lastly, they appointed vicars, or deputies, clothed with their authority, for the preservation of order and tranquillity in the remoter provinces." (Mosheim, 'Ecc. Hist.' Cent. v., pt. ii., chap. 2.) There were, however, provinces of the empire which were exempt from their jurisdiction.

The Greek Church is at present governed by four patriarchs, namely, those of Constantinople, Jerusalem, Antioch, and Alexandria.

PATRICIANS (*Patres, Patricii*, in Latin) was the appellation of the members of the original houses or gentes, of which the Roman populus, the ruling power in the community, was at first composed, and of their descendants, either by blood or adoption. They were originally divided into three tribes, the Ramnes, Tities, and Luceres; each tribe into ten curiæ, and each curia into ten decuriæ, which Niebuhr has identified with the gens or house. The Luceres were admitted later to the rank, and were styled gentes minores, in opposition to the other two tribes, styled majores. Each house became subdivided into several familiæ, which were distinguished by a surname, in addition to the name of the gens, which was common to all, like that of the Scotch clan. Thus the gens Cornelia comprised the families of the Scipiones, the Lentuli, the Sullæ, &c. The families composing a gens were not necessarily related by consanguinity, for individuals might be adopted into a gens, and under the early Roman kings such admissions were frequent. The definition of a gens by Scævola (Cic., 'Top.,' c. 6) is, that the members bore a common name, were descended from freemen, without any stain of slavery among their ancestors, and had never incurred any legal disability; they had common sacred rites, or sacrifices appointed for stated days and places. When a family became extinct by default of heirs in the male line, its property reverted to the gens of which it formed a part. Gentile and patrician were therefore synonymous. Freedmen and their descendants belonged to the gens of which they bore the name, but they had not the rights of the gens, that is to say, the gentile rights. Natives of the confederate towns of Latium coming to settle at Rome attached themselves to some gentile family, the head of which was styled their patron, and they were styled his clients. [CLIENT.]

The members of the senate, the consuls, and the pontifices were, in the first ages of the republic, chosen exclusively from among the patricians, until the year 365 B.C., when Licinius carried his rogations, by which the plebeians were admitted to the consulship, as well as to the custody of the Sibylline or sacred books. [LICINIUS STOLO, in BIOG. DIV.]

When the plebeians became eligible to all the offices of the state, a new nobility was formed, consisting of those who had filled the offices of consul, prætor, or curule ædile, and this nobility was transmitted to their posterity with the "Jus imaginum," or the right of setting up in their houses the images of their ancestors. Still a distinction in opinion continued to prevail in favour of the patricians, or older nobility, as distinguished from the plebeian families.

When Constantine transferred the seat of the empire to his new city, he established there a new senate and a new patrician order, the members of which were appointed by the emperor. Their privileges consisted in being freed from certain taxes and jurisdictions, and wearing the chlamys and calceus. After the fall of the Western Empire, the officers sent by the Byzantine emperors to administer the provinces of Italy subject to them, were chosen from among the patricians of

Constantinople. Thus we read in the history of the dark ages, of the "patrician of Rome," meaning the governor or representative of the Eastern emperor in that city, and the title was afterwards assumed by Charlemagne and his successors.

At Venice the title of patrician was given to the members of the great council, or supreme legislature, and their descendants, and their names were registered in the golden book. After the decree of February, 1297, called "La serrata del maggior consiglio,' no new member was introduced into the council, but all the descendants of those who had once sat in the great council, on arriving at twenty-five years of age, were by right members of the sovereign assembly, and patricians of Venice. "Patrizio Veneto" was a title of nobility, considered equal to that of any feudal noble not of a sovereign house.

In other parts of Italy, such as Genoa and Rome, the word patrician was and is still used in common language to denote a member of the hereditary nobility, independently of any feudal title.

PATRISTIC THEOLOGY. [THEOLOGY.]

PATRON. [BENEFICE; PARISH.]

PATRO'NUS, derived from *pater*, a "father," as *materna* is formed from *mater*, a "mother." The relation of Patron and Client (*cliens*) in ancient Rome is discussed in the article CLIENT; but the relation between a freedman (*libertus*) and his patronus requires a few words of explanation.

In the Roman polity persons were divided, with respect to status or condition, into freemen (*liberi*) and slaves (*servi*). Freemen were again divided into persons who were born in a state of freedom (*ingenui*), and those who had been manumitted (*libertini*). A manumitted slave was called *libertus*, that is, *liberatus*, "freed," and his master who manumitted him became his *patronus*. The slave who was manumitted received the gentile name of his patronus. (See Lactant. 'Div. Instit.' iv. 3.; Plin. 'Hist. Nat.' xxv. 3, and xxxi. 3; Pers. 'Sat.' v. 78.) The relation between patronus and libertus resembled in many respects that between patronus and cliens; but it appears that their mutual rights and obligations were rather regulated by public opinion than fixed by any positive enactment. The patronus on the one hand was bound to take the libertus under his protection; and the libertus on his part was bound to assist his patronus by every means in his power, but the only case in which he was compelled by the law to do so, was when the patronus or his children had become too poor to support themselves. In such a case, if the patronus or his children proved to the satisfaction of the governor of the province (*præses*) their necessitous condition, he might direct the libertus to allow a monthly payment for their support (D. 25. 3. 9).

The most important part however of the connection between the patronus and the libertus was the right which the former had in certain cases to the property or a portion of the property of the latter upon his death. This right was founded upon the fact, that the law regarded patroni as the adgnati of their liberti, and consequently they succeeded to the property like any other adgnati. By a law of the Twelve Tables, if the libertus died intestate and left no heir (*suus heres*), the patronus succeeded to his property. (Gaii. 'Comm.' iii. 40; Justin. 'Inst.' iii. 8. 1.) If the heir was a son born of his own body (*naturalis*), no one had a right to complain; but it appeared to the Romans a great injustice that an adopted son or daughter, or a wife (*in manu*), should deprive the patron of his right to the property. This injustice was remedied by the prætor's edict, which enacted that the patron's right should be barred only by the libertus leaving natural sons, whether under his power at the time of his death, or sui juris, or adopted by another during his life, provided they had not been disinherited, and that if a libertus who had no natural sons made a will, he should be obliged to leave half of his property to his patronus; and if he left none of his property, or less than half, the bonorum possessio of half should be given to the patronus, even against the words of the will; if the libertus died intestate, leaving an adopted son, a wife (*in manu*), or a daughter-in-law (*in manu filii ejus*), half of the property was also given to the patronus. ('Gaius,' iii. 40, 41; 'Institut.,' iii. 8. 1.)

By the Lex Papia the rights of patrons to the property of their rich freedmen were still further increased. By this law it was enacted, that if a libertus died leaving property to the value of 100,000 sesterces, a portion of his property (*virilis pars*) went to his patronus, whether he had made a will or died intestate, provided he had fewer than three children. If he left only one son or one daughter, half of his property went to his patronus, as if he had died leaving no son or daughter; if he left two children, a third went to the patronus, but if three, the patronus had no claim to any portion. (Gaius iii. 42; 'Institut.,' iii. 8. 2.)

With regard however to the property of a liberta, the ancient law sufficiently protected the rights of the patronus, and he therefore had no occasion to have recourse to the edict of the prætor. For since the patronus was the tutor of the liberta, she could not make a will without his consent, and consequently could not leave her property to any one else. (Gaius, iii. 43; Ulp., 'Fr.' xxix. 2.) The Lex Papia however set free a liberta who had brought forth four children from the tutela of her patronus. (Gaius iii. 44; Ulp., 'Fr.' xxix. 3.)

The patrona, previous to the passing of the Lex Papia, had no greater right to the property of the libertus than was granted to the patronus by the Twelve Tables, and could not, like the patronus, obtain by the prætor's edict the half of the property of a libertus who had left only an adopted son or a wife or daughter-in-law. By the Lex Papia, however, an ingenua patrona, who had brought forth two children, and a libertina patrona, who had brought forth three, obtained almost the same rights as the patronus possessed by the prætor's edict; and an ingenua patrona who had brought forth three children obtained the same privileges as were given to the patronus by that law; but a libertina patrona in no case obtained the rights granted to the patronus by the same law. (Gaius, iii. 49, 50; Ulp., 'Fr.' xxix. 5, 6.)

The rights of a patronus to the property of a libertus only extended to his direct heredes, sons, grandsons, great-grandsons, &c., and never belonged to his collateral heirs (*extranei heredes*). (Gaius, iii. 58.) A patronus was able to assign a libertus (*adsignare libertum*) to one of his sons to the exclusion of his other children, so that on the death of a libertus, the son to whom the libertus had been assigned was alone entitled to the property, which was due to the patronus by the jus patronatus. ('Institut.,' iii., tit. 9; 'Dig.,' 50. 16. 107.)

All the preceding remarks respecting the succession of the patronus to the property of the libertus, only apply to the property of those liberti who were Roman citizens. Those liberti who were Latini [LATINUM JUS], or Dediticii, had in fact no power over the disposal of their property. The Latini liberti had the privileges of freemen while alive, but "they lost their life and their liberty at the same time," and their property, like the *peculia* of slaves, came by the Lex Junia to the persons who had manumitted them (Gaius., iii., 56; 'Institut.,' iii. 8.4.) The succession to the property of the liberti Latini differed also in many other important particulars, which Gaius has pointed out (iii. 57-62), from the succession to the property of those liberti who were Roman citizens. By a decree of the senate passed in the reign of Claudius during the consulship of Lupus and Largus, it was enacted that the property of the Latini should pass first to those who had manumitted them and their children not disinherited by name, and afterwards to their other heirs. (Gaius, iii. 63; 'Institut.,' iii. 8.4.) By a constitutio of Trajan, it was enacted that if a Latin libertus obtained from the Emperor the jus Quiritium without the knowledge or against the will of his patronus, he should enjoy the privileges of a Roman citizen while he lived, but should be regarded as a Latinus at the time of his death, and should have no power of leaving his children as his heredes; and that he should only be allowed to make a will so far as to leave his patronus his heir, or if the latter were unwilling to become his heir, of substituting another in his place. (Gaius, iii. 72.) This constitutio however was a little altered by one of Hadrian, who gave with certain conditions the same privileges to those Latini who had obtained the jus Quiritium from the Emperor, as to those who had obtained it by a decree of the senate or the Lex Ælia Sentia. (Gaius, iii. 73.)

These laws were however very much altered by Justinian. He gave to the liberti Latini and Dediticii the same privileges as those liberti possessed who were Roman citizens. He also enacted, that if a libertus or liberta left less property than amounted to the value of 100 aurei, the patronus had no claim to any portion of the property, provided they made a will; but if they died intestate, leaving no children, then the patronus succeeded to the property by the law of the Twelve Tables. If the property of the libertus or liberta was of more value than 100 aurei, and they left children, the patronus had also no claim to any part of the property; but if those liberti or libertæ who left no children died intestate, the patronus succeeded to the whole of the property, and if they made a will without leaving any part of their property to the patronus, then he had a right to a third of the property, and not to a half, as was formerly the case. ('Instit.,' iii. 8.3.)

(Gaius, iii. 39-76; Ulpian, *Fragm.*, xxvii. 1-5; xxviii. 7; xxix. 1-7; *Institutiones*, iii., tit. 8, *De Successione Libertorum*; tit. 9, *De Adsignatione Libertorum:* Digest. 37, tit. 14, *De Jure Patronatus*; 38, tit. 2, *De Bonis Libertorum;* 38, tit. 4, *De Adsignandis Libertis; Collatio Legum Mosaic. et Roman.*, xvi, 8, 9; Unterholzner, *Ueber das patronatische Erbrecht*, in the *Zeitschrift für Geschichtliche Rechtswissenschaft*, 5th vol., 1st part, Berlin, 1823; and the articles CLIENT, LATINUM JUS, and LIBERTINUS, in this work.)

PATRO'NYMIC (*πατρωνυμικὸς*) is a name given by grammarians to those words which express the name of a person's father or ancestor. Thus Achilles is called Pelides (the son of Peleus), Agamemnon is styled Atrides (the son of Atreus), &c. In the English language we have no words of this description, but in Sanscrit and Greek they are very common, especially in Sanscrit, which has as many as thirteen different terminations to form such words, namely, *a*, *aki*, *âyana*, *âyani*, *âyanya*, *inêya*, *îrya*, *êya*, *êra*, *aira*, *kâyani*, *ki*, *ya*. In Greek the most common masculine termination is *ides*, as *Cecrop-ides*, a descendant of Cecrops; some patronymics are formed by adding *ion*, as *Kron-ion*, the son of *Kronos*, &c. Feminine patronymics in Greek are commonly formed by adding *id* (in the nominative *is*), as *Tantal-is*, gen. *Tantal-id-os*, the daughter of Tantalus. In Lithuanian some patronymics are formed by adding *na*, as *Janow-na*, the son of Janow or John (Pott's 'Etymologische Forschungen,' vol. ii., p. 579); which termination may perhaps be connected with the Latin *an-us*, which forms such patronymics as *Octavi-anus*, one of the family of Octavius, *Æmili-anus*, one of the family of *Æmilius*, &c. In English, though not very correctly, the surname is often styled the patronymic.

PATTERNS. Connected with the subject of patents is the copyright of designs. By recent Acts of Parliament (5 & 6 Vict. c. 100; 6 & 7 Vict. c. 65; and 13 & 14 Vict. c. 104—known respectively as "The Designs Act, 1842;" "The Designs Act, 1843;" and "The Designs Act, 1850"), the inventor, or purchaser, or proprietor of any new design for ornamenting any article of manufacture of a useful character in respect of the pattern, or the shape, or the external appearance, may register such design, and thereby secure the sole right of applying it for a period of three years, subject to extension at the discretion of the Board of Trade.

Provision is contained in the later Act for provisional registration for one year.

The person intending to register must take or send to the office of the Registry of Designs, 1, Whitehall, two copies or drawings of his design; one of which will be filed by the registrar, and the other returned to the party registering, with a certificate, which certificate is made evidence of registration.

Every article manufactured according to such design must have thereon the number of the design in the register, and the date of the registration.

Any person pirating a design thus protected is liable to a penalty of from 5*l.* to 30*l.* for each offence, which may be recovered by an action at law, or by summary proceeding before two magistrates.

Registered designs may be transferred from one person to another, in which case the latter is entitled to be registered as the proprietor. Printed forms of such transfers are supplied at the office.

The commissioners of the Treasury have power to fix the fees payable upon registrations, transfers, &c. These fees are of very moderate amount.

PAUPERISM. [POOR LAWS.]

PAUSE. [ORATORY; PUNCTUATION.]

PAVEMENT. [ROADS.]

PAVIIN. A crystallisable substance found by Professor Stokes in the bark of the horse-chestnut. It is remarkable for exhibiting a beautiful bluish-green fluorescence when placed in violet light. It is supposed to be identical with *fraxin*.

PAVING. [ROADS.]

PAVO (the Peacock), a constellation of Bayer, which occupies a part of the space situated between Sagittarius and the South Pole. Its principal stars are as follows:—

Character. (None in Bayer.)	No. in Catalogue of Lacaille.	No. in Catalogue of British Association.	Magnitude.

PAWN. [PLEDGE.]

PAWNBROKERS. All persons who receive goods by way of pawn or pledge for the repayment of money lent thereon at a higher rate of interest than five per cent. per annum, are pawnbrokers. The character of the individual to whom the money is lent is scarcely a subject of consideration with the lender; he may be satisfied, if he believe that the articles pledged are not stolen or come by in an unlawful manner.

Pawning differs from other ways of lending and borrowing money in this, that the goods of the borrower are delivered to the lender as a security. [PLEDGE.] Otherwise, when the lender has confidence in the integrity and solvency of the borrower, he is often satisfied with a written engagement from the borrower, and if it should be required, with the additional engagement of some other person. When further security is required by the lender, it may be land, or shares in a ship, or it may be something which is not in its nature capable of immediate tradition, as the future benefit to accrue from a policy of insurance; but all these kinds of security are different from that given in pawning, and are treated under the articles MORTGAGE and SHIPS.

The business of lending money on pledges is in many countries carried on under the immediate control of the government as a branch of the public administration; and where only private individuals engage in it, as in this country, it is placed under regulations. Thus in China, where pawnbrokers are very numerous, Sir J. F. Davis, in his work on the 'Chinese,' says "they are under strict regulations, and any one acting without a licence is liable to severe punishment. The usual period allowed for the redemption of the pawned goods is three years. The highest legal rate of interest on deposits is three per cent. per month; but in the winter months the money advanced on wearing apparel may not exceed two per cent., on the alleged ground that poor persons may be able the more easily to redeem."

During the existence of the Usury Laws in this country, which fixed the maximum legal rate of interest at five per cent. per annum, a higher rate was nevertheless chargeable by pawnbrokers under the section of the 39 & 40 Geo. 3, c. 99, an act which is still in force, and which regulates the various rates of interest on goods or chattels pawned according to the following scale:—

For every pledge upon which there shall have been lent any sum not exceeding 2*s.* 6*d.*, the sum of ½*d.*, for any time during which the said pledge shall remain in pawn not exceeding one calendar month, and the same for every calendar month afterwards, including the current month in which such pledge shall be redeemed, although such month shall not be expired. If there shall have been lent the sum of 5*s.*, one penny; 7*s.* 6*d.*, one penny halfpenny; 10*s.*, two-pence; 12*s.* 6*d.*, two-pence halfpenny; 15*s.*, three-pence; 17*s.* 6*d.*, three-pence halfpenny; 20*s.*, four-pence; and so on progressively and in proportion for any sum not exceeding forty shillings; but if exceeding 40*s.* and not exceeding 42*s.*, eight-pence; if exceeding 42*s.*, and not exceeding 10*l.*, after the rate of three-pence for every 20*s.*, by the calendar month, including the current month, and so on in proportion for any fractional sum. Parties may redeem goods within seven days after the expiration of the first calendar month without paying interest for the extra seven days; or within fourteen days on paying for one month and a half; after which time interest is charged for two calendar months. But in case the interest has accumulated throughout a series of months, the pawnbroker is not entitled to calculate it for a single month, taking advantage of an indivisible fraction, and then multiply the result by the number of months. The calculation in the first instance should be for the whole time at the rate allowed by law so as to avoid the injustice done the pawnor by the other method.

Pawnbrokers are required by the Act to keep books in which all goods taken in pledge must be entered and described, the sum advanced upon them, and the name and abode of the pledger, and whether he is a housekeeper or a lodger. They make out at the time two memoranda of these particulars, one of which is given to the pledger. For this duplicate, when under 10*s.*, one halfpenny is charged; 10*s.* and under 20*s.*, one penny; 1*l.* and under 5*l.*, twopence; 5*l.* and upwards, fourpence. Articles pledged for sums above 5*s.* must be entered in the pawnbroker's books within four hours; and those on which 10*s.* or upwards have been advanced must be entered in a separate book and numbered, the first entry in each month commencing No. 1. The number and description of the pledge in the books and on the duplicate correspond with each other. Articles cannot be taken out of pawn without the production of the duplicate, the holder of which is presumed to be the owner; but the original pawnor has a perfect right to sell the duplicate, and the pawnbroker is obliged to deliver the goods to the purchaser on the production of the duplicate with the principal and interest due on the pledge. If a duplicate be lost or stolen, the pawnbroker is required to give a copy of it to the party representing himself as the owner of the articles pledged, with a blank form of affidavit, which must be filled up with a statement of the circumstances under which the original duplicate was lost, and sworn before a magistrate. For this second duplicate the pawnbroker is entitled to demand one halfpenny, if the sum advanced does not exceed 5*s.*; from 5*s.* to 10*s.*, one penny; and afterwards in the same proportion as for the original duplicate.

The penalty against unlawfully pawning goods the property of others is between 20*s.* and 5*l.*, besides the full value of the goods pledged; and in default of payment, the offending party may be committed for three months' imprisonment and hard labour. Persons forging or counterfeiting duplicates, or not being able to give a good account of themselves on offering to pawn goods, are liable to imprisonment for any period not exceeding three months. Pawnbrokers or other persons buying or taking in pledge unfinished goods, linen, or apparel entrusted to others to wash or mend, are to forfeit double the sum advanced and to restore the goods. The Act empowers police-officers to search pawnbrokers' houses or warehouses when suspected to contain unfinished goods unlawfully pledged, and goods unlawfully pawned must be restored to the owner by the pawnbroker. Goods that have been stolen and pawned may be ordered by the judge or magistrate before whom the thief is convicted to be restored to the real owner; and without proceedings against the thief they may be recovered by the owner in an action at law against the pawnbroker.

All pawned goods are deemed forfeited at the end of one year. If redeemed, the pawnbroker must endorse on his duplicate the charge for interest, and keep it in his possession for one year. Articles on which sums have been advanced of 10*s.* and not exceeding 10*l.*, if not redeemed, must be sold by auction, after being exposed to public view and at least two days' notice having been given of the sale. The catalogue of sale must contain the name and abode of the pawnbroker, the month the goods were received, and their number as entered in the books and on the duplicate. Pictures, prints, books, bronzes, statues, busts, carvings in ivory and marble, cameos, intaglios, musical, mathematical, and philosophical instruments, and china, must be sold separate from other goods, on the first Monday in January, April, July, and October in every year. On notice not to sell given in writing, or in the presence of one witness, from persons having goods in pledge, three months further are allowed beyond the year for redemption; and if the owner tender principal and interest and demand delivery of the goods any time before sale, the pawnbroker is not afterwards entitled to sell them. But in the fact of selling unredeemed pledges there is no further warranty implied by law on the part of the pawnbroker than that the goods are unredeemed pledges, and that he is not cognisant of any defect of title attaching to them. An account of sales of pledges above 10*s.* must be entered in a book kept by the pawnbroker, and if articles are sold for more than the sum for which they were pledged, with interest thereon, the owner is entitled to the surplus, if demanded within three years after the sale. Pawnbrokers' sale books are open to inspection on payment of a fee of one penny. The penalty on pawnbrokers' selling goods before the proper time, or injuring or losing them, and not making compensation to the owner, according to the award of a magistrate, is 10*l.* They are required to produce their books on the order of a magistrate in any dispute concerning pledges, and are not to purchase goods which are in their custody. The Act extends to the executors of pawnbrokers.

The Act prohibits pledges being taken from persons intoxicated or under twelve years of age. (By the 'Metropolitan' Police Act (2 & 3 Vict., c. 47), a fine of 5*l.* is inflicted upon pawnbrokers taking pledges from persons under the age of sixteen.) Pawnbrokers are prohibited from buying goods between the hours of 8 A.M. and 7 P.M.; and by the 9 & 10 Vict., c. 98 from receiving pledges between Michaelmas-day and Lady-day before 8 A.M. or after 7 P.M.; and for the remainder of the year, before 7 A.M. or after 8 P.M., excepting on Saturdays and the evenings preceding Good Friday and Christmas Day, or any public fast or thanksgiving day appointed by the Crown, when the hour for closing is extended to 11 P.M. They are required to place a table of profits and charges in a conspicuous part of their places of business.

Pawnbrokers are required to take out an annual licence from the Stamp-Office; and, to enable them to take in pledge articles of gold and silver, a second licence is necessary, which costs 5*l.* 15*s.* Those who carry on business within the limits of the old Twopenny Post pay 15*l.* a-year for their licence, and in other parts of Great Britain 7*l.* 10*s.* The licence expires on the 31st July, and a penalty of 50*l.* is incurred if it is not renewed ten days before. No licence is required in Ireland, but those who carry on the business of a pawnbroker must be registered. Any one who enters into secret partnership with a pawnbroker for the purpose of carrying on that business, even although the agreement stipulates only for a right to inspect the books and to receive a per centage on the business done, renders himself liable to penalties under the statute. But to repress the practice of laying frivolous and unfounded informations against this class of tradesmen, the 2 & 3 Vict. c. 71, ss. 32-35, giving power to magistrates to award amends in such cases, to inflict penalties on common informers who compound informations, to diminish the amount of the portion awarded of the penalty to any informer, and further to diminish the term of imprisonment fixed in the case of offenders, is extended by the 22 & 23 Vict. c. 14 to the 39 & 40 Geo. 3, c. 99, and to all parts of England, and to all magistrates, justices, or justices of the peace.

The act for the regulation of pawnbrokers in Ireland is the 28 Geo. III., c. 43 (Irish statute). It requires pawnbrokers to take out licences and to give securities; appoints the marshal of the city of Dublin corporation registrar of licences; directs returns to be made to him monthly, upon oath, of sums lent; and allows the registrar a fee of one shilling on each return. The Act requires the returns to be laid before parliament; but this is not done, and in some other particulars the statute is but imperfectly observed.

PAX, an ecclesiastical instrument of ancient use in the Roman Catholic church. St. Paul, in several of his epistles, commands the professors of the Christian religion to "salute each other with a holy kiss." That this was literally practised in the first ages of the church, we learn from the apostolical constitutions, together with some particulars respecting the method of performing this ceremony. "Let the bishop salute the church, and say, *The peace of God be with you all:* and let the people answer, *And with thy spirit.* Then let the deacon say to all, *Salute one another with a holy kiss,* and let the clergy kiss the bishop, and the laymen the laymen, and the women the women." (Li. viii., c. 11, apud Coteller, p. 345.)

The custom of giving the kiss of peace before the communion, in the more solemn service of the Roman Catholic Church called the High Mass, is still kept up among the officiating clergy, as well as among the men and women of the different religious orders. So also it appears to have been practised by the laity during the middle ages; while the men and women were separated from each other. But when the sexes began to be mixed together in the less solemn service called the Low Mass, which began to take place in the 12th or 13th century, a sense of decorum dictated to the bishops the use of an instrument called sometimes a *Pax*, sometimes *Tabula Pacis*, and sometimes *Osculatorium*, which the priest kissed first, then the clerk, and lastly the people who assisted at the service, one after another, instead of the former kiss.

Among the constitutions of Walter de Grey, archbishop of York in 1250, an osculatorium was one of the regular ecclesiastical ornaments, or rather implements, ordered to be provided in every parish church.

It was usually in the form of a metallic plate or tablet, with a support at the back, and had a representation of the crucifixion in front, either in relief or engraved. The magnificent pax of silver, engraved in niello, by Finiguerra, is still preserved at Florence. In the South Kensington Museum is a remarkably fine pax of Italian work of near the close of the 15th century. The central plate is of bronze, on which is a representation in relief, attributed to Botticelli, of the Virgin under a canopy, surrounded by angels. This is set in a gilt mounting, enriched with silver filagree work; while the support is ornamented with three small niello plates. Many others are extant, which are admirable examples of the metallic art of the time.

The general disuse of this plate in modern times is attributed by Le Brun ('Explication Litterale, &c., de la Messe,' tom. i., p. 595) to certain jealousies which were found to arise among individuals, about priority in having it presented to them.

The use of the Pax was not among the ceremonies which were first abrogated at the Reformation in England: on the contrary, it was enforced by the ecclesiastical commissioners of Edward VI., and rendered more ostensible than it had been, as appears by the following injunction, published in the deanery of Doncaster, in 1548:—"The clerk shall bring down the paxe, and standing without the church-door, shall say loudly to the people these words: 'This is the token of joyful peace, which is between God and man's conscience,'" &c.

PAYMENT. If a man owes several sums of money to another on different accounts, and makes a payment of any one of such sums, he may state at the time of payment on which account such sum is paid, and the payment will be considered to be legally appropriated to the debt which he has named. If at the time of payment the debtor makes no appropriation of the payment, the creditor may at the time of payment appropriate it to such debt as he pleases, provided he so appropriates the payment, as he would do, or as it may be presumed that he would do, if he were the debtor. Accordingly the creditor must appropriate the payment to such debt as is the most burdensome to the debtor. If neither party make any appropriation of the debt at the time of payment, the payment will be presumed to be made on account of the more burdensome debt; if there is no difference in the quality of the debts, the payment must be presumed to be made on account of the oldest.

These are the rules of the Roman Law ('Dig.' 46, tit. 3), which perhaps may be considered to be adopted by the English Law, though the decisions are by no means uniform in this matter. (Devaynes *v.* Noble, 1 Mer. 606.) The principles just laid down apply to distinct debts on different accounts (causae). If there are dealings between two persons which are all of one uniform and continuous nature, as for instance between a banker and his customer, there is no question of appropriation of payment. The customer pays money into the bank at different times, and draws it out by drafts at different times. All the sums paid in and all the sums paid out severally make an entire creditor and debtor account, and by striking the balance at any given time it will appear what sum is due at that time from the banker to his customer or from the customer to his banker. It is true that this supposes a kind of appropriation, but not exactly that kind which is meant by the term. It assumes that the sum first paid in is discharged by the sum first paid out, so far as it is sufficient to discharge it; and the same remark applies to all subsequent payments into the bank and sums drawn out. The account therefore must be made out in the order of time, and the balance will show how the account stands at the time when it is made out. (Devaynes *v.* Noble.)

A debt barred by the Statute of Limitations cannot be revived by an appropriation of a general payment.

There are various other cases in the reports in which the question of appropriation of payments has been discussed. (Croft *v.* Lumley, 6 H. of L. Cas. 672; Beale *v.* Caddick, 2 H. & N. 326; Nash *v.* Hodgson, L. J. 25, Ch. 186; and Farley *v.* Turner, L. J. 26, Ch. 710.)

PEA. The garden pea (*Pisum sativum*) is a native of the south of Europe, but sufficiently hardy in a young state, or when its development is not much extended, to bear our winters when they are moderate, and when the plants have, as in gardens generally, a sheltered situation.

The pea had probably been introduced into this country at an early period, for peas are mentioned by Lydgate, in the time of Henry VI., as being hawked in London. It appears however that for nearly a century afterwards, they were either not very common, or the manner of obtaining them early was unknown, for Fuller states that in the reign of Elizabeth peas were brought from Holland, and were accounted "fit dainties for ladies, they came so far and cost so dear."

The varieties of the pea are numerous. Every seedsman issues a trustworthy list, from which selection is to be made according to the date of sowing.

The soil for peas ought to be fresh and well stirred, but not too rich; for in the latter case a luxuriant growth is induced without fertility.

The times of sowing are, in November for the earliest crop, and at intervals of a month, three weeks, or a fortnight, as the season advances, till Midsummer. The produce from any that may be sown after this period is very uncertain; as is indeed the case with the November and other sowings previous to those of spring. The shelter afforded the young plants in winter by spruce branches or temporary awnings is of course beneficial.

The distance which should be allotted for the intervals between the rows of peas may be three, four, five, or six feet, according to the growth of the sort and richness of the soil. The plants should not be allowed to grow too thick in the rows, otherwise they are drawn up slender, without a due proportion of foliage on the lower part of the stem, which, in that case, as well as the leaves depending on it, is apt to become unhealthy and to mildew.

Agricultural Cultivation.—The common pea is cultivated in the garden and in the field, and there are several varieties of it. The plant is naturally a creeper, having numerous tendrils, by which it lays hold of stronger plants and supports itself. The pods contain one row of round seeds, which at first are soft and juicy, in which state they are used for the table under the name of green peas. They afterwards harden and become farinaceous, and the stem dries up. In this state they are thrashed and stored for use like corn, and serve chiefly to fatten hogs. The straw is given to cattle and sheep in winter.

There are some varieties of peas the stems of which do not rise or creep, but remain short, and hence are called dwarf peas. These are preferred for early sowing in the garden, and likewise when they are cultivated in the fields to be gathered in a green state. Every gardener strives to raise early peas, and the first which are brought to the London market are sold for a very great price. As soon as they are more common, such quantities are sometimes raised in the fields, that the price scarcely defrays the expense of gathering and bringing to market. When the market is not overstocked, this crop is very profitable, as it does not exhaust the land, and there is good time for a crop of tares or turnips after the peas in the same season. But the usual purpose for which peas are cultivated in the regular course of husbandry, is to fatten sheep and hogs. A white sort, which readily splits when subjected to the action of millstones set wide apart so as not to grind them, is used in considerable quantities for soups, and especially for sea stores. There is also a blue sort which answers the same purpose. The hog pea is of a gray or dun colour.

Peas contain much farinaceous and saccharine matter, and are therefore highly nutritious; no other seed surpasses them in this quality, except the seed of the French bean (Phaseolus). But this is refused by most animals in the raw state, owing to a certain toughness, which makes them adhere to the teeth; and, even when boiled, they are not relished by them.

As food for hard-working men, peas are excellent when well boiled and mixed with some animal fat. In some countries peas-meal is baked into hard cakes, with or without oatmeal or barley-meal. These cakes are nutritious, but are of difficult digestion, except where custom and hard labour have inured the stomach to their use.

The soil best suited to the growth of peas is a light or sandy loam of some depth, and in good heart; the usual preparation of it is by repeated deep ploughing and pulverising with harrows or other instruments. It is not advisable to manure the land immediately for peas, as it makes them throw out abundant stems at the expense of the produce in pods. They follow well after barley in which no clover has been sown, and are a good substitute for clover where there would be a danger from the too frequent repetition of clover on the same land. When clover has failed, peas supply its place, the ground being ploughed up before winter, or early in spring, and well pulverised. The wheat is not generally so good after peas as after clover, when the clover is a good crop; but it is well known that if the clover fails, the wheat will also suffer. It is therefore better to have peas than to risk sowing wheat after a thin crop of clover. If the peas are not well hoed, and do not cover the surface, the land will be full of weeds; but with good management it may be looked upon as a cleansing crop. Many farmers consider peas as a very uncertain crop: but they are only so when the land is carelessly cultivated. They are, no doubt, often injured by want of moisture in the soil, or by an excess of it; but deep ploughing will prevent the former, and careful draining the latter. If peas are sown on land which is exhausted, or naturally very poor, no certain crop can be relied on. It sometimes happens however that an excellent crop is obtained against all probability, considering the state and tillage of the land, owing to some fortunate coincidences of favourable weather; and in this case it would appear as if great care in the preparation of the soil were unnecessary; but this is not often the case, and no prudent farmer will trust to the chances, which are much against success. In nine cases out of ten a slovenly cultivation or an improper succession of crops is the cause of great disappointment and loss, and it may be laid down as a general rule, that no good farmer will trust to accident, when by a little care and attention and a reasonable expenditure he may almost ensure success.

Peas must not be repeated on the same land in less than 10 or 12 years, nor are they to be recommended on very stiff clays, on which beans are to be preferred. Wherever beans suit the soil, they are a much better preparation for wheat than peas, admitting of much more frequent and perfect hoeing, besides the application of an abundant coat of dung, of which the wheat reaps the benefit as well as the beans.

Peas should be sown as early as the ground will admit of being worked; and in very mild winters January is a very good time for sowing peas, which are intended to be gathered green, in a sheltered situation sloping towards the south-west. The hog peas may be sown in February or March; and if they are horse-hoed, and the earth is raised against the young plants, they will not suffer from a moderate frost. When peas are drilled at two feet or more between the rows, it will not take above two bushels to drill an acre. The old method of sowing peas broadcast and ploughing them in is now seldom practised, and to sow them and harrow them in is nowhere recommended; the birds in this case having much too great a share of the seed. When peas follow clover, the practice of dibbling them into the sward, which has been turned over with the plough, is much to be preferred. Wherever dibbling is generally practised, and there are sufficient hands to put the seed into the ground in a reasonable time, it should be preferred for every kind of crop that can admit of the hoe in the intervals.

When peas are sown later than usual, it is useful to steep the seed a few hours, in order that it may vegetate the sooner. A week may often be gained in the coming up of the crop by this means.

The Everlasting Pea, which is so well known in our gardens, has been recommended to be cultivated in the fields for green fodder for horses, which are said to eat it readily. In land which has been well manured, it will produce a very great weight of green food; and there are probably varieties of it more succulent and sweeter than others. If it could be established in a field, it would produce abundant food for several years in succession, without any other cultivation than hoeing out the weeds and stirring the soil around the plants. The seed should be sown in rows, and the plants thinned out by the hoe, so as to stand a foot or 15 inches apart; they would then have room to grow out, and would cover the ground completely. By transplanting year-old plants, a still greater crop might be obtained. It is at least worth a trial.

Peas should be drilled in rows at such a distance as to admit the horse-hoe between them. They should be horse-hoed repeatedly until the stems are so long as to fall down and cover the intervals: a slight earthing of the rows with a plough has the effect of keeping the stems from the ground and allowing the air to circulate under them, by which the podding is much encouraged; for in wet seasons the stems are apt to lie on the wet ground and to rot. When the seed is ripe in the pods on the lower part of the stalks, the crop should be reaped, or many of the pods will burst, and the seed be lost. The reaping is performed by pulling the straw from the root by hand, or by means of two reaping-hooks, which partly tear up the stems, and partly cut them off. They are then gathered into small loose heaps, and left to dry. After being turned over till they are quite dry, they are carted to the stack or barn. Unless the quantity be considerable, so as to make a large stack, it is advisable to put them in a barn. When the peas are stacked, many of the pods are necessarily exposed to the depredation of birds; and, if they escape this, they burst, and the seed is lost.

The produce of an acre of good peas is from 30 to 40 bushels, and the price about the same as that of beans. They are consequently a profitable crop, and will well repay a little attention in the cultivation. If the land is not in sufficient order and heart to make it advisable to sow wheat after the peas, barley or oats may be advantageously substituted. If the peas fail, it may be necessary to clean the land with a fallow crop before any other corn is sown, for a bad crop of peas invariably leaves the land foul.

The straw or haulm of peas, when well harvested, makes excellent fodder for cattle, and especially for sheep, which are very fond of the dry pods when the seeds have been thrashed out.

In some places, they sow peas and beans together broadcast, and plough them in; the beans serve as a support to the peas, and a greater return is expected; but unless it be for the purpose of cutting them up for green fodder, as soon as the pods are formed, this practice is not to be recommended. In Flanders, peas, beans, tares, and barley are sometimes sown thick together, and form an abundant green crop, which is cut as soon as the flower is past, and given to the cows and pigs, which thrive well on this succulent food. The surface of the ground is so completely shaded, that no weeds can spring up; and as there has been no seed formed, little is taken from the soil. The land is immediately ploughed up, and sown with another crop, such as potatoes or turnips, which sometimes are off the ground in time to allow wheat to be sown the same year.

The nutritiveness of the pea as food is explained by analysis, which shows that air-dried peas generally contain about one quarter of their weight of flesh-forming constituents; one half their weight of starch, sugar, fat; and the rest fibre, water, and ash. The mineral part of the ash of the whole plant contains a very large proportion (40 per cent.) of lime, and 17 or 18 per cent. of the alkalies.

PEACE OF RYSWICK. [TREATIES, CHRONOLOGICAL TABLE OF.]

PEACH. The peach-tree (*Amygdalus Persica*, or *Persica vulgaris*) is generally considered to be more especially a native of Persia. It was known to the Romans, and brought to Italy, where it became distinguished by the name of *Persica;* and this name it still retains under various modifications in the different countries of Europe. But the peach is not indigenous solely in Persia, for it has been found growing wild in various parts of Turkey and Asia. Pallas describes it as existing in the more southern parts of the Caucasus. From the frequency of its occurrence in a wild state, and the perfection which it attains under the most limited share of cultivation in regions situated between 30° and 40° of latitude, these parallels may be presumed to include its favourite habitat. Isothermal lines describe however a wavy tract, and the peach may even find a congenial climate to a considerable extent on both sides of the above limits; but the locality must be very peculiarly circumstanced in which it will acquire full perfection beyond the 48th parallel on the one hand; and, on the other, its deciduous nature, requiring a cool season of rest, unfits it for the continued high temperature of a tropical climate.

The peach withstands our winters unhurt, trained against a wall, if they are not unusually severe. It even succeeds in America exceedingly well as a standard, in latitudes where the winters are much more intense, but the summers hotter, than with us. This is in conformity with the well-ascertained fact, that all deciduous trees suffer less from severe frost in winter when their wood is perfectly matured by sufficiently warm summers, than when grown in climates where they cannot enjoy that degree of summer-heat which they are naturally adapted for, and which they require for the due formation of their tissues. Hence, in the north of England, young peach-trees in the open ground will be partially injured by a degree of frost which, though of equal intensity, will not injuriously affect similar plants in the neighbourhood of London. The peach also succeeds as a standard in Italy, the south of France, and other continental countries of Europe having summers equally hot; but it may be observed that, where the mean temperature of the summer months is above 70°, or that of the warmest month above 75°, as is the case at Rome, and still higher at New York, the *melting* varieties of the peach do not possess that rich succulence which they acquire against a south wall under the more moderate summer heats of the climates of London or Paris. On the contrary, however, the *firm-fleshed* or *clingstone* peaches, which are little esteemed in this country, are preferred in America and other places subject to extreme summer heat.

If the mean temperature of February amount to 40°, and that of March to 44° or 45°, the peach-tree will be in full flower against a wall with a south aspect about the last week in March; and the general crop will be ripe in the last week of August or first week of September, provided the mean temperature of April be 49°, May 55°, June 61°, July 64°, and that of August 63°. This period of *five* months required for the maturing of the fruit from the time of flowering, on the open wall, may be reduced to *four* by means of fire-heat and the protection of glass; but it cannot be advantageously diminished any further. This fact being borne in mind, it is easy for the gardener to know at what time to commence forcing his peaches in order to obtain a crop in a given month.

From the natural climate and habit of the peach-tree, it is obvious that when forced it must be flowered under a comparatively low degree of temperature. It cannot, therefore, be well forced simultaneously with the vine; for the temperature of March, which in this climate serves to bring the peach into flower, does not unfold the buds of the vine, this being only effected a month or six weeks farther in the season, by a mean temperature of 55°. The peach may be subjected at first to a temperature of 45°, but not exceeding 55° till the flowering is over, after which it may be gradually raised to 60°, and not exceeding 65°, till the substance of the stone is indurated, after which from 65° to 70° may be allowed. This is to be understood as referring to the application of fire-heat. Even in the total absence of fire-heat, sun-heat will frequently raise the temperature much higher; but in this case a large portion of air should be supplied, not however all at once after the temperature of the house is found too high, but gradually as the temperature increases. Air should be always freely admitted through the day, when the weather is at all favourable.

Light is so essential, that unless peaches be trained near the glass, the fruit will neither acquire due colour nor flavour. Vicissitudes of dryness and moisture must be avoided. The roots should be well supplied with water before the fruit begins to ripen off, because at a later period none can be applied without deteriorating the flavour.

The management of the peach-tree can only be correctly understood by those who are aware of the disposition of its buds and its mode of bearing. The leaves on the shoots of the current season are produced either singly, in pairs, or in threes from the same node. In the course of the summer, or early part of autumn, a bud is formed in the axil of every individual leaf, and these are termed single, double, or triple *eyes*, or buds, according as one or more are produced at each node. In the following season, these buds develope themselves either as flower-buds or young shoots, and previously to pruning it is necessary to distinguish the one description from the other. The flower-buds are plump and roundish; the wood-buds are more oblong and pointed, and one of these is generally situated between flower-buds in the case of triple buds occurring at the same node. It is therefore expedient, in pruning, to shorten a shoot to these triple eyes if possible, or, in their absence, to a leaf-bud, but never to a fruit-bud only, for no shoot could be prolonged from it, nor would the fruit attain perfection, owing to the want of leaves in immediate connection with its footstalk. In selecting buds for the purpose of propagation, *single* wood-buds only should be chosen.

The mode of bearing is solely on shoots of the preceding summer's growth.

The peach is propagated almost exclusively by budding; but occasionally splice-grafting is adopted. The peach stock is rarely used, but frequently the almond, especially in France. In this country, however, it is propagated almost entirely on the plum stock, which is not only much hardier, but also possesses the property of spreading its roots nearer the surface than either of the two preceding kinds, thereby affording to the peach a more congenial nourishment, in consequence of the roots being within the influence of the solar heat. Whereas the peach stock tends to strike downwards strong tap-like roots beyond the depth of the stratum warmed by the summer-heat; and although the latter trees grow vigorously for a few years, or so long as the roots have not penetrated too deep, yet they afterwards become sickly, their foliage becomes narrow, and acquires a yellowish colour, and the trees ultimately perish. The *mussel* and *white pear-plum* are the varieties of plum stocks on which the peach is budded; the latter is esteemed the best. The French prefer the St. Julien plum stock, which answers exceedingly well. In order to obtain varieties, the seed is used, and when the plant is sufficiently advanced it is grafted.

The peach succeeds in any rich fresh loamy soil; but the subsoil, like that for all fruit-trees, ought not to be retentive, and a very complete mode of drainage is absolutely necessary. It would also be desirable that the roots should not be allowed to penetrate deeper than two feet from the surface, which is to be effected by judicious root-pruning. No objections could be made against the roots following their natural tendency downwards to whatever distance they might go, if their extremities were at the same time in a medium congenial to the peach as regards temperature; but this cannot be the case in Britain, unless perhaps some chalk subsoils may form exceptions. The soil, especially if the situation is cold and damp, can hardly be too shallow when it rests on a hard subsoil; on gravel it need not exceed 14 inches in depth, but may be deeper in warm and dry situations. The best remedy for mildew is, to take up the tree carefully in autumn, renew the soil, and replant the tree, spreading the roots near the surface.

Various modes of training the peach have been adopted, with different degrees of success. That of course has proved the best which admits of the most equal distribution of sap throughout the respective branches, and likewise the production of a sufficient number of well-placed shoots for replacing those that have once borne fruit, the shoots being only useful for such purpose in the season immediately following that in which they are produced. The fan method, and a modification of it called Seymour's training, are most in conformity with the above principles. A common error in the fan method is that of disposing a few of the first produced branches so as to represent equidistant radii; the consequences of such disposition are an excessive degree of vigour in the central and most upright; but at the same time those inclining horizontally become comparatively weak, linger for a few years, and then die off. Their share of the sap is soon appropriated by the more vertical branches, some of which will assume the character of stems, and prove unsuitable for producing fruit-bearing shoots. Cutting these back is frequently the only alternative in order to obtain other shoots for the purpose of furnishing the lower part of the wall. By this misdirection of the energies of the tree, several years' growth is wasted; and when it becomes necessary to cut out such large branches, the tree receives a shock which renders it incapable of bearing such fine fruit as a more skilful management will ensure. It may be briefly affirmed that all methods of training are bad which admit upright shoots to compete with horizontal ones; for the former will grow with a vigour ten times greater, in many instances, than the latter, owing to the strong vertical tendency of the sap. Although the ascendancy gained by a vertical shoot over a horizontal one is considerable in the current season of their production, yet it bears but a trifling ratio to that which would be gained in successive seasons, were the vertical portion allowed to proceed without interference from the pruning-knife. If, however, a central vertical shoot be annually trained, and uniformly cut at the winter pruning to within a few buds from its base, no material injury would then result to the side branches, the vertical tendency against them being thus limited to a single summer-shoot. This principle is the basis of the following mode of training.

In cutting back the central shoot, two buds, well situated for producing side branches, and a third for an upright, must be left. The first production of side branches, which are intended to produce the lower radii of the fan, must be trained at some elevation in the first instance, and afterwards brought to a horizontal position; and they should not be subdivided. Those, however, obtained in the following season may be allowed to form two each, if sufficiently vigorous, at some distance from their base, and as their divergence affords room. The branches produced after those last mentioned, and indeed all the upper ones, may be subdivided into two, or even three. By this method of training the lower branches become strong, and acquire a well-established communication with the roots before the upper are in existence, so that there is little danger of their dying off, as usually happens when horizontal and vertical branches are started at the same time.

By repeating the process here detailed, all the principal branches are ultimately produced, to the number of between thirty and forty, and disposed in a fan-like form, diverging, not exactly from a common centre, but from a short axis. These branches support the shoots on which, during the second season of their existence, the fruit is borne. Buds for the origin of these shoots should be selected at the distance of every twelve or fourteen inches along the upper side of the branches, that being the side from which they are obtained with the greatest facility, owing to the upward tendency of the sap. As these shoots are being prolonged during the summer, they should be trained so that their foliage may have the fullest exposure to light; but although the foliage of one shoot ought not to overshade that of others, yet the naked branches are benefited by the shade of leaves, for old bark exposed to the direct rays of the sun is apt to be scorched.

The shoots produced and trained during the summer for successional bearing ones must be shortened considerably at the ensuing winter's pruning, and care must be taken not to cut above a node where there is only a blossom-bud or buds, but to one that is seen to have a wood-bud—that is, such as a shoot will proceed from. In the following spring, the blossom-buds are unfolded, and soon after the wood-buds begin to push the rudiments of shoots, one of which, next the base of each fruit-bearing shoot, must be preserved and encouraged with special care, in order to supply the place of those that are bearing fruit. The fruit-bearing shoots being useless for such purpose a second time, must therefore be cut away at the following winter pruning, when the young shoot, retained during the summer, is shortened like its predecessor, and trained for the purpose of bearing fruit and producing a successor, which likewise becomes subject to the same routine treatment.

The preceding directions are to be followed in order to the essential pruning, the development and maintenance of the form of the tree; but as a great number of superfluous shoots will be produced, the mode of their removal requires to be noticed. The operation is termed disbudding, and it commences as soon as the young shoots can be laid hold of, but should be completed in a gradual manner. A portion of such front-shoots as have no fruit at their bases are first removed, then part of those elsewhere situated, making exceptions of the lowest on each bearing shoot, for succession, and of the terminal one. By degrees all are removed excepting the two last mentioned and those from nodes where fruit is set and promises to attain perfection. Finally, the terminal ones and those left on account of having fruit at their bases are shortened, or stopped, to about three inches in length, or so as to have several leaves for the purpose of maintaining the flow of sap and elaborating it for the nourishment of the fruit. Should these or the terminal shoots again push, such secondary shoots must be pinched off above the second leaf from the origin.

Thinning the fruit is generally done much too sparingly. The vigour of the tree should of course be taken into consideration. As a general rule, one fruit on each bearing shoot, or two at most, are all that ought to be left. By leaving too many, the size of the fruit is diminished, so that the aggregate weight of flesh is probably but little if at all increased, whilst that of stones, to the great weakening of the tree, becomes materially so. Some remove the flower-buds to a considerable extent, a practice which is very proper. It is advisable however to preserve several on each shoot, in order that a choice may be made of one or two of those likely to take the lead.

The surface of the border should be frequently stirred; and when the weather is dry, watering will be necessary both for the border and foliage; but the use of cold spring water must be avoided. The ravages of the green fly (*Aphis Persicæ*) must be carefully guarded against. The best known remedy is to dust the tree, after syringing, with snuff, or powdered tobacco leaves. Coping-boards, made to project about a foot, are of great utility in protecting the blossoms; but after the danger of frost is over, the coping ought to be removed.

The best varieties of peaches in cultivation at the present day in this country appear to have been obtained from France. Although designated by various English names, most of the sorts have been traced to be synonymous with the French peaches. They are numerous and often changing.

(*Hort. Trans.*; *Guide to the Orchard and Kitchen Garden*; London, *Encyclopædia of Gardening*; MacIntosh, *Book of the Garden*.)

PEAR, the wild pear-tree (*Pyrus communis*), from which the numerous cultivated varieties have originated, has a wide indigenous range extending over a great part of Europe and Asia, within the limits of temperate regions. It is to be met with in certain localities in the southern parts of Britain. The old varieties of pear are however getting rapidly out of cultivation, and giving place to others of recent origin, superior in quality, and much better adapted for this climate than the old kinds appear ever to have been. Few of the latter could be successfully cultivated without the aid of walls; whereas most of the new varieties produce abundance of excellent fruit on standards or dwarfs in the open ground. Even in France the old varieties are now decaying, although the climate is there most congenial to them.

The pear is chiefly propagated by grafting or budding on the wild pear stock, or on stocks raised from the seeds of cultivated pears, called free stocks; the former are however to be preferred. It is also grafted on the quince, which is most proper for dwarf trees, or for moist soil, and has also the effect of bringing the trees earlier into a bearing state. It may be also grown upon the medlar, and the white thorn (Cratægus Oxyacantha), but on these the disparity of growth between the respective stems occasions a short duration of the union. The enlargement of the pear-stem in the case of strong growing varieties is indeed generally too much for quince stocks. There are several varieties of the quince, and the sort that has the broadest leaves and which has the nearest correspondence in regard to horizontal growth with that of the pear should be preferred for stocks.

The pear-tree will thrive in any rich loamy soil; but it is only where the subsoil is naturally congenial, or rendered so artificially, that it will continue to produce good crops of well flavoured fruit. A clay subsoil is bad, and so is in fact any other that will hold water. Good drainage is absolutely necessary, and shallow planting cannot be too much recommended. The monks in former times were aware of the advantages arising from having the roots near the surface; for stones and slates have been found below old fruit-trees, which had been planted at monasteries once in their possession.

Manure is not so liable to prove injurious to the pear and apple as it is to stone-fruits. On the contrary, unless the trees be growing too strong, manure, judiciously applied, will always prove beneficial.

Pears are deemed worthy of the expense of walls, but this is often an unnecessary expenditure for want of a properly formed border, and thorough draining, where the subsoil renders such necessary. Brick-rubbish is a good bottoming; or a bed of concrete, two or three inches thick, laid sloping from the wall towards a drain in front, is unquestionably one of the best modes that could be practised; and it is the only effectual one to prevent the roots from penetrating beyond a limited depth; for they will often find their way through a stratum of stones or brick-rubbish. The depth of soil need not exceed 2½ feet. The best season for transplanting is in the beginning of winter, or as soon as the leaves have fallen in autumn.

Standard trees may be planted from 20 to 30 feet apart, or where vegetables are intended to be cultivated, the distances may be 40 feet between the rows and 20 feet in the rows. Dwarf trees, or quince stocks, will not require more than 15 feet distance. Wall-trees should be at least 20 feet apart, and for some varieties 30 feet will not be too much.

The modes of training the pear-tree are various. Against walls, the three principal methods are the fan-shape, its reverse the pendulous, and intermediately the horizontal, which is that most generally adopted. In the fan method the central part of the tree, from the upright position of the branches, or their near approach to such, is apt to become too strong. On the contrary, the pendulous training induces debility when the trees begin to bear heavy crops. By annually cutting back a central shoot to about a foot, and training branches horizontally, right and left, the vigour of the tree is equally distributed. It often happens that in this mode the branches only produce fruit towards their extremities. When this is the case, a shoot should be encouraged near the origin of the horizontal branch, and trained in the interval, and at some distance, say three feet; farther along the branches another may be laid in a similar manner, and so on, care being taken that each is stopped when its elongation reaches the place where another has its origin. These shoots will generally become as fruitful, after two or three years, as the portion of wood of the same age near the extremities of the branches themselves.

Training against espaliers was formerly more practised than at present. The difficulty of getting the old varieties to bear apart from a wall, together with the expense of erecting the espalier, and the liability of its materials to decay, have no doubt tended to bring this mode into disuse. It is however worthy of remark, that a greater extent of foliage can be exposed to direct light by espalier training than by any other on an equal extent of ground. New varieties will do away with the objection of unproductiveness; and although the contact of metallic substances is not congenial to vegetable growth, yet the principal supports of the espalier might be constructed of cast-iron, which would prove an ultimate saving; the small intermediate wood-work that would be requisite could be easily replaced.

In the cultivation of pears as standards, the head is allowed to take nearly its natural course, being only subjected to such regulations, by pruning, as are necessary to preserve the equality of the principal branches with regard both to strength and distance; and likewise to render the whole sufficiently thin, in order that the sun's rays may be freely admitted.

In some situations, many kinds of pears remain long unfruitful; the best means of rendering them otherwise is of course a most important desideratum. So long as circumstances are very favourable for the growth of wood, blossom-buds are not likely to be produced; the production of the latter results from a more inspissated state of the juices; and will not take place whilst a copious flow of sap is continued. This may be interrupted by ligature, ringing, grafting, or other analogous means. But these means frequently afford only a temporary remedy, and a repetition of the process is at the expense of the energies of the tree, so that it is rendered too weak for future bearing. There is still a more important object which the above means are not calculated to affect. If the roots are in a cold subsoil or out of the reach of solar influence, the fruit will only acquire an inferior degree of flavour. If however the tree be carefully removed (for doing which autumn is the best season), the soil well dug, or even renewed, and the tree deprived of such roots as cannot be brought to a horizontal position, namely, that in which all the others should be placed when replanted, and if this be done as shallow as possible, a satisfactory check will be occasioned, fruitfulness induced, and flavour communicated.

The management of dwarf standards is similar to that required for tall standards, excepting that the head is formed at the height of one or two feet from the ground, instead of six, the usual height allowed for the stems of standard trees in orchards, or where under-cropping is carried on, as in market-gardens, where the dwarf-headed trees would obstruct the growth of vegetables for a considerable distance from their stem. Dwarfs however have some important advantages; a large head is sooner formed, and the fruit is not so liable to be blown down.

The French modes of training *en Quenouille* or *en Pyramide* cannot be strictly adopted in this country with advantage, owing to the richness of the soil and moisture of the climate, circumstances which are favourable to the production of shoots rather than fruit buds, and this tendency is farther encouraged by shortening the shoots to the extent which the French recommend. In both these modes tiers of branches proceed from a central stem; in the pyramidal form the branches are horizontal, each tier being successively shorter than the one below. In the Quenouille the branches are curved downwards, and this mode might be successfully practised in this country, by leaving the shoots at full length, care being taken that all upright shoots are shortened in summer.

The pruning of standard pear-trees is usually confined to the winter regulation of the branches by thinning, and shortening where the subdivision of branches is desirable or where they are too weak. Wall and espalier trees require both a summer and winter pruning. In summer a number of shoots will be produced beyond that which will be required for training. If these are allowed to grow without interruption during a considerable part of the season, and then at once cleared away, the tree is apt to receive a shock from which it does not soon recover. If the shoots are shortened too much or too early, the buds, which would otherwise have proved blossom buds in the following spring, will immediately become excited (other channels for the flow of sap being cut off), and burst into shoots. [MORPHOLOGY.]

In order to avoid this, which is a case of frequent occurrence, a portion of these superfluous shoots should be first stopped at an early period, and afterwards another portion: by the middle of June part of them may be cut back to within two or three inches of their base; and thus by degrees the whole will be ultimately reduced, without any great or sudden derangement of the general flow of the sap. The winter pruning is attended with less vital danger to the tree. It consists chiefly in shortening spurs to the lowest fruit-buds and judiciously thinning them.

If borders are well made, there will be less occasion for raising the trees after they have been once planted. Still, after four or five years, it will, under all circumstances, prove advantageous to remove the trees from the wall, trench the border, and replant, spreading the roots near the surface in a horizontal direction, or inclining slightly downwards. Cutting the roots, without entirely removing the tree, is attended with the disadvantages arising from the partial loosening of the soil, and the difficulty of reaching the perpendicular portions of the root.

PEAR-GAGE. The principle of Smeaton's pear-gage, for measuring the exhaustion of a receiver, by means of the AIR PUMP, differs from that of the other gages, in that the measurement does not take place until after the air has been re-admitted into the receiver. Suppose a wire working through a collar in the top of the receiver and supporting a tube open only at the lower end. Under the tube is a cup of mercury, standing on the floor of the receiver, so that by lowering the wire the open end of the tube may be immersed in the mercury. The exhaustion being made before lowering the wire, the air in the tube will be rarefied equally with that in the rest of the receiver. If the wire be then lowered, and the air re-admitted into the receiver, the mercury will rise in the tube until the elastic force of the recompressed air in the tube, together with the column of mercury, counterbalances the pressure of the external air. A gage attached to the tube shows, by the height of the mercury, what was the original rarefaction.

Now it is plain that while the ordinary gages show the actual amount of elastic force left in the receiver, the pear-gage submits the air, or whatever else there may be, to a process of compression before the measurement is made. If there be nothing but air, all the gages agree; but if, as generally is the case, there be also vapour, the pear-gage shows a much higher degree of apparent exhaustion, than the ordinary gage.

PEARLASH. [POTASSIUM.]

PEARL FISHERY. The fisheries which are carried on to supply the market of the world with pearls are numerous, and some of them are of very ancient date. The fishery at Catifa in Arabia, which produced the pearl bought by Tavernier for 110,000*l.*, was celebrated in Pliny's time. In the Old World, the west coast of Ceylon, that of Coromandel, and the Persian Gulf, are among the more prominent stations. The Algerine coast and the Sooloo Islands also furnish a certain share. In the New World, the neighbourhood of St. Margarita, or Pearl Island, and other localities on the coast of Colombia, furnish a great many, and the Bay of Panama also contributes considerably; but the pearls from the Western world, though many of them are large, cannot be compared with those of the East in shape, colour, and general beauty.

The Bahrein Islands (Persian Gulf) give a most abundant harvest of these beautiful molluscous secretions; perhaps the most abundant in the world. Sixty thousand tomauns of Bassorah, about 90,000*l.* sterling of our money, and often more, are derived from the fishery in about two months, the time during which it lasts, the commencement being in June. There is no monopoly; any one may engage in the adventure upon payment of a tax on the produce to the government. The Persians principally are engaged in it, and the divers are of that nation.

The Western pearl fisheries, especially those on the coast of Colombia, must have been very valuable once. Seville alone is said to have imported upwards of 697 lbs. in the year 1587. The second Philip's celebrated pearl, which weighed 250 carats, and was valued at 150,000 dollars, came from Margarita. These prizes were not forgotten in 1825, when joint-stock companies raged. One company undertook the prosecution of the Colombia fishery, and another embarked in that of Panama and the Pacific, both with about the same success; for in 1826 they were abandoned. Some fine specimens of the shells of Mollusca were sent home by one of them. The Algerine ground was also, we believe, undertaken by an English company in 1826.

The pearls which are the objects of these fisheries are found in the shells of *Meleagrinæ*, or pearl-oysters, as they are called, and principally in those of the species named *Avicula* or *Meleagrina margaritifera*. The best ground is considered to range at depths varying from 6 to 8 fathoms; and the divers, who usually are unhealthy and short-lived, are said to be able to remain generally from a minute to a minute and a half under water. Two minutes, four, and even six, have been mentioned; but constructed as the human respiratory and circulating system is, we should think the last-mentioned periods must be very rare. A submersion of a minute and a half is calculated to do mischief enough in ordinary cases.

Ceylon affords a good example of the commercial system under which the pearl-fishery is carried on. The bay of Condatchy is the most central rendezvous for the boats employed in the fishery. The banks, where it is carried on, extend several miles along the coast from Manaar southward off Arippo, Condatchy, and Pomparipoo. The principal bank is opposite to Condatchy, and lies out at sea about twenty miles. After the survey of the state of the beds and the consequent report to government, the particular banks to be fished are put up for sale to the highest bidder, and are usually purchased by a native merchant. The government however sometimes judges it more advantageous to fish the banks on its own account, and to dispose of the pearls to the merchants. The banks are divided into three or four different portions, which are fished annually in succession. These portions are completely distinct, and are set up separately to sale, each in the year in which it is to be fished. A sufficient interval is thus given to the oysters to attain their proper growth; and as the portion first used has generally recovered its maturity by the time the last portion has been fished, the fishery becomes almost regularly annual, and may thus be considered as yielding a yearly revenue. The oysters are supposed to attain their complete state of maturity in seven years. The fishing season commences in February, and ends about the beginning of April. The period allowed to the merchant to fish the banks is six weeks or two months at the utmost; but there are several interruptions which prevent the fishing days from exceeding more than about thirty. If it happen to be a very bad season, and many stormy days intervene during the period allotted, the purchaser of the fishery is often allowed a few days more. Previous to the commencement of the fishery, all the boats rendezvous at Condatchy, and it is here that they are numbered and contracted for. They regularly sail out and return together. They reach the banks before day-break, and at sun-rise commence fishing. In this they continue busily occupied till the sea-breeze, which arises about noon, warns them to return to the bay. When the boats come to land, their cargoes are immediately taken out, as it is necessary to have them completely unloaded before night. Each boat carries twenty men, with a tindal, or chief boatman, who acts as pilot. Ten of the men row and assist the divers in re-ascending. The other ten are divers; they go down into the sea by five at a time; when the first five come up, the other five go down; and by this method of alternately diving, they give each other time to recruit themselves for a fresh plunge. In order to accelerate the descent of the divers, large stones are employed. Some of the divers use a stone shaped like a half-moon, which they fasten round the belly when they mean to descend, and thus keep their feet free. They fearlessly descend to the bottom in from four to ten fathoms water in search of the oysters. The diver, when he is about to plunge, seizes the rope to which one of the stones is attached, with the toes of his right foot; while he takes hold of a bag of net-work with those of his left. He seizes another rope with his right hand, and holding his nostrils shut with his left, plunges into the water, and by the assistance of the stone speedily reaches the bottom. He then hangs the net round his neck, and with much dexterity and all possible despatch collects as many oysters as he can while he is able to remain under water. He then resumes his former position, makes a signal to those above by pulling the rope in his right hand, and is immediately by this means drawn up and brought into the boat. These men will often make from forty to fifty plunges in one day, and at each plunge bring up about a hundred oysters. Some rub their bodies over with oil, and stuff their ears and noses to prevent the water from entering; while others use no precautions whatever. The chief horror and danger awaiting the diver are concentrated in the ground-shark. This animal is a common and fearful inhabitant of all the seas in these latitudes: and its terrors are so continually before the eyes of the divers, that they seek a vague safety in supernatural means.

The divers are paid differently, according to their private agreement with the boat-owners, either in money or with a proportion of the oysters caught, which they take the chance of opening on their own account: the latter is the method most commonly adopted. The agreements with the people who hire out the boats are conducted much in the same manner. They contract either to receive a certain sum for the use of their boats, or pay the chief farmer of the banks a certain sum for permission to fish on their own account. Some of those who pursue the latter plan are very successful and become rich, while others are great losers by the speculation. The spirit of gambling is more openly exhibited, for oyster lotteries are carried on to a great extent, and they consist of purchasing a quantity of the oysters unopened, and running the chance of either finding or not finding pearls in them. As soon as the oysters are taken out of the boats, they are carried by the different people to whom they belong and placed in holes or pits dug in the ground to the depth of about 2 feet, or in small square places cleared and fenced round for the purpose, each person having his own separate division. Mats are spread below them to prevent the oysters from touching the earth, and here they are left to die and rot. As soon as they have passed through a state of putrefaction and have become dry, they are easily opened without any danger of injuring the pearls. On the shell being opened, the oyster is minutely examined for the pearls; it is usual even to boil the oyster, as the pearl, though commonly found in the shell, is not unfrequently contained in the body of the fish itself.

Captain Percival, in his account of Ceylon, states that in preparing the pearls, particularly in drilling and stringing them, the natives are wonderfully expert. A machine made of wood, and of a shape resembling an obtuse inverted cone, about six inches in length and four in breadth, is supported upon three feet, each twelve inches long. In the upper flat surface of this machine holes or pits are formed to receive the larger pearls, the smaller ones being beat in with a little wooden hammer. The drilling instruments are spindles of various sizes, according to that of the pearls; they are turned round in a wooden head by means of a bow handle, to which they are attached. The pearls being placed in the holes, and the point of the spindle adjusted to them, the workman presses on the wooden head of the machine with his left hand, while his right is employed in turning round the bow handle. During the process of drilling, he occasionally moistens the pearl by dipping the little finger of his right hand in a cocoa-nut filled with water, which is placed by him for that purpose; this he does with a dexterity and quickness which scarcely impede the operation, and can only be acquired by much practice. The Cingalese have also a variety of other instruments both for cutting and drilling the pearls. To clean, round, and polish them to the state in which we see them, a powder, made of the pearls themselves, is employed. These different operations in preparing the pearls occupy a great number of the natives in various parts of the island. In the black town or pettah of Columbo in particular, many of them may every day be seen at this work.

The Chinese adopt a singular mode of procuring pearls by artificial means, that of compelling or inducing the fish to make them. They force open the shell of a large river mussel, and put in a small bit of wood or metal. The fish becomes irritated, and covers the intruding substance with a pearly deposit. Very often small clay figures are thus introduced, representing Buddha in the sitting posture in which that image is most frequently pourtrayed. It has been stated that no less than 5000 families are engaged in this singular branch of industry near Ningpo. Some of these pearl-covered figures of Buddha are to be seen in the South Kensington Museum.

The beautiful substance called (somewhat expressively) *mother of pearl*, is the hard, lustrous, brilliant internal layer of shells, especially oyster shells, and more particularly the pearl oyster. In English oysters this substance is too thin to be workable for manufacturing purposes; but the oysters of the eastern seas yield it of considerable thickness. The brilliant hues which distinguish mother of pearl do not depend upon the nature of the substance, but on an exquisitely fine series of furrows upon the surface, which shed a brilliant reflection of colours according to the angle at which the light falls on them. Much care is required in working this delicate substance; but it may be cut by saws, files, and drills, with the corrosive aid of sulphuric or muriatic acid. It is polished by colcothar of vitriol. In all those ornamental manufactures where *pearl* is said to be used for flat surfaces, such as inlaying, mosaics, buttons, knife-handles, &c., it is not real pearl, but mother of pearl, that is employed; and the quantity now consumed in England, especially at the manufacturing establishments of Birmingham and Sheffield, is very large. An instance has been recorded of a ship arriving at London from Panama with more than *two million* pearl shells.

PEARL WHITE. [Bismuth, *Nitrate of.*]

PEAT: *Economical Uses.* Peat is a substance of vegetable origin, found wherever the soil has been long soaked with water which has no outlet and does not completely evaporate by the heat of the sun. When dried peat is examined, it is found to consist of roots and fibres in every stage of decomposition, from the natural wood to the completely black vegetable mould. From the nature of its formation under the surface of water, it acquires a portion of tannin, which has the property of preserving animal and vegetable matter from decomposition. Hence large branches and trunks of trees are found imbedded in peat, which have no mark of decomposition, except what may have taken place before the wood was completely immersed in the peat. Peat contains all the elements of the richest manure, and may by an easy process be converted into humus: for this purpose the agency of alkalies is the most effectual. If the tannin be decomposed, decomposition of the vegetable fibre will go on, and soluble humus will be formed. When peat is newly dug up, if caustic lime be added to it before it is dry, the moisture of the peat slakes the lime, which acts on the gallic acid in the peat and neutralises it. If this mixture be then excited to fermentation by the addition of animal matter, such as urine or dung, oxygen is absorbed and carbonic acid evolved; and the residue is converted into an excellent manure, containing much soluble humus. The same may be effected more slowly by mixing peat with clay or marl, and allowing the mixture to remain exposed to the atmosphere for a considerable time, frequently turning it. But nothing accelerates this process like the addition of putrescent animal matter, which acts as a ferment and greatly hastens the decomposition. The soils for which peat forms the best manure are the chalky and clayey. Sand has too little tenacity; it lets the gases produced by the decomposition escape, instead of attracting them, as clay and chalk do, and preventing their escape.

The burning of peat destroys the vegetable matter and leaves the earths and salts behind. They are accordingly very strong stimulants to vegetation, especially that of clovers and herbaceous plants, of which the leaves and stems are the most valuable parts. If the soil is well furnished with vegetable matter, and capable of bringing an abundance of seed to perfection, it may be very useful to apply stimulating manures, such as peat ashes, to increase the verdure; but on poor soils destitute of humus, the increase of the stems and leaves does not ensure a proportionate increase of seed. Hence it is often remarked that soot, potash, saltpetre, and similar substances produce a deceitful growth, giving a rank green leaf, which is not succeeded by a heavy ear; but, on the contrary, the produce in seed is rather diminished than increased by the use of the manure. Whenever a stimulating manure is used, the soil should be naturally rich, or enriching manure should be applied at the same time.

Where a great extent of peat-moss renders the improvement of it desirable, there are various ways in which it may be reclaimed. In some places the peat has been removed, and the loam which lay below it was found of a very fertile nature. This could only be done on the banks of rivers, into which the peat was floated by means of small canals dug through it, and communicating with the river. In all other cases the mode adopted has been that of draining and consolidating. In draining a peat-moss the water must not be let off too rapidly, for in that case the surface may become so loose and dry, that no vegetation can take place in it. If the water is drained off so as to leave two feet of peat dry above its level, this is all that is required for a beginning. The best improvement, and the most rapid, is produced by bringing sand or gravel in sufficient quantity to cover the surface with two or three inches of it. This will make a beginning of a soil, in which potatoes may be planted. At first the surface will not bear the wheels of a cart nor the tread of a horse; but in a short time a solid crust will be formed, which will increase in strength and thickness as cultivation advances. There are many fine pastures in Scotland which once were brown peat-mosses, on which it would have been dangerous for a man to walk, but which now bear heavy oxen, and seem as solid as any pasture on a clay subsoil. Manuring and liming are the most effective operations in bringing about this great improvement. Potatoes and oats are usually the first crop on reclaimed peat-mosses. It is long before they become capable of bearing wheat; nor is this crop to be recommended at any time, unless there be a good depth of soil formed over the peat. Laying down to grass as soon as a certain degree of improvement has been made, and depasturing with sheep at first and cattle afterwards, tend more than any other means to consolidate the surface and deepen the mould, which gradually increases by the decomposition of the tannin in the peat.

Great attention has been paid within the last few years to the question how far peat can be practically applied in the arts, thereby rendering a double service—clearing bog-land for agricultural purposes, and making good use of the substance taken from it. As Ireland contains 3,000,000 acres of bog, the inquiry really becomes an important one. Several years ago, a patent was obtained by Mr. Williams, managing director of the Dublin Steam Navigation Company, for compressing peat into a dense mass, so as to resemble coal. The process is as follows:—Immediately after being dug, the peat is triturated under revolving edge-wheels faced with iron plates perforated all over the surface, and is forced by the pressure through these apertures, till it becomes a species of pap, which is freed from the greater part of its moisture by a hydraulic press. It is then dried, and converted into coke in the same manner as is done with pit coal. The factitious coal of Mr. Williams is made by incorporating pitch or rosin melted in a cauldron with as much of the peat-charcoal ground to powder as will form a tough doughy mass, which is then moulded into bricks.

The use of peat for fuel is too well known to require notice; but it may be interesting to know how peat fuel is made in Holland, where it cannot be dug out of the solid moss but is brought up in the form of mud from a considerable depth under water. It is raised by means of small strong nets, fixed by an iron ring to a long pole, in the manner in which canals are cleared of mud. This liquid peat is brought in boats to a place prepared for its manufacture, which has been levelled as a brick-yard usually is. The soft mud is spread over this to the depth of six inches, and the water is allowed to drain off slowly. When the peat begins to dry, men fix boards to their feet and walk over it, so as to compress it; and as soon as it will bear cutting, it is cut with a spade made on purpose into oblong pieces of the usual size of peat, which is about eight or nine inches long and five wide; the treading and drying have reduced the thickness to about four or five inches. When completely solid, these peats are set on edge, and afterwards stacked loosely, so that the air may pass through them. In some places they have sheds, for the purpose of protecting them from rain. They soon become very hard, and burn more like wood or coal than the peat which is cut immediately from a solid moss. They give a very great heat, and form a coal which, when it is shut up in a close vessel to stop the combustion, and allowed to cool, has a considerable resemblance to charcoal.

Dutch peat is used as fuel for all the purposes of manufactures, except for the forging of iron, for which coals are imported from England and the Netherlands. The peat-fens in Holland, however, begin to be exhausted, and the fuel is so dear, that it is found more economical to import coals from England, which are used chiefly in cast-iron stoves.

In Ireland, some years ago, the Irish Amelioration Society encouraged the conversion of peat into charcoal. The charcoal obtained from this source is found to be valuable not only for smelting-furnaces, but also as a deodoriser. Around each charcoal factory, in some parts of Ireland, a rim of cottage gardens was gradually formed; and the land, relieved from the load of otherwise unprofitable peat, produced useful crops. Whether, however, from the commercial value of the product having been overstated, or for some other cause, the making of charcoal from peat still remains only a small branch of industry in Ireland. A British and Irish Peat Company was afterwards formed, suggested with reference to Dartmoor peat rather than to that of Ireland; but if available for one, it would also be for the other. The company professed to be able to obtain naphtha, paraffin, fixed oil, volatile oil, acetate of lime, and sulphate of ammonia, from peat, at profitable prices; and very sanguine accounts were published as to the rate of profit obtainable. When the Earl of Clarendon was Lord Lieutenant of Ireland, he commissioned Sir Robert Kane to inquire into and report upon the various proposed plans for economically applying the millions of acres of peat in Ireland. One difficulty is, that all attempts to expel the water from wet peat by mechanical means alone have been found defective; and another is, that the profitableness of applying heat to evaporate the moisture is doubtful. In the peat taken from the Bog of Allen, it is found that 100 tons of the wet substance produce only 16 tons of dry peat. Mr. Reece, whose patent led to the formation of the Irish Peat Company, found that by the destructive distillation of 1000 parts of peat, he obtained about eleven of sulphate of ammonia, seven of acetate of lime, two of wood naphtha, one of paraffin, seven of fixed oil, and three of volatile oil. When Sir Robert Kane tested this statement he found it to be pretty nearly correct; but when he proceeded to inquire into the profitableness of the process as a manufacture of the above-named substances, the conflicting evidence quite baffled him. From the reports of Kane and other authorities, the area of all the bogs in Ireland, multiplied by the average thickness, would it appears yield the enormous quantity of 4,000,000,000 tons of peat even when quite dry; and some enthusiasts have given to this a money value of more than 1,000,000,000*l.* for fuel. A village has been lighted with peat gas in Westmeath. It remains true, nevertheless, that although a mass of peat is a vast storehouse of chemical material, manufacturing operations relating thereto have not yet become important.

PECK, a measure of two gallons, or the fourth part of a bushel. [BUSHEL.] It is used as a measure of dry goods only.

PECTASE. [PECTIC ACID.]

PECTIC ACID. PECTIN. The jelly of certain fruits, as the currant, gooseberry, &c., is distinguished from gelatin, or animal jelly, in containing no nitrogen. Pectic acid was first obtained by Braconnot, so named by him from the Greek *pectis* (πηκτίς); and whenever pectin is treated with an alkali, pectic acid is formed. As these substances are intimately connected, they may be considered together.

Pectin may be obtained from many fruits by carefully expressing their juice, and evaporating it at a temperature not above 212°. It may also be procured by adding alcohol to recently expressed currant or gooseberry juice; in a few hours a gelatinous substance separates, which is to be washed with weak alcohol and then dried; in this state it resembles isinglass in appearance, and when immersed in cold water it swells like starch.

Another method has been given for preparing pectin, which is that of mixing the clear expressed juice of currants with that of sour cherries, when pectin falls down; the liquid being poured off, the pectin is to be washed with cold water as long as it comes away coloured.

Hot water has less action upon dry pectin than cold water has: in dilute and boiling alcohol it dissolves slightly; the solution however is not very adhesive. Pectin has no acid properties, nor does it render iodine blue like starch. When pectin is treated with nitric acid, it yields oxalic acid and mucic acid, accompanied with a trace of a bitter yellow matter: hydrochloric acid is rendered of a fine red colour by it when they are heated together, and red flakes separate, which are not soluble in ammonia. Pectin has also been found in the bark of most trees.

Pectic acid is obtained whenever carbonate of potash is added to pectin, but carbonate of soda does not produce this effect, nor does ammonia. Lime-water, however, partially converts pectin into pectic acid.

Pectic acid is perhaps most conveniently obtained from the carrot; for this purpose the rasped root is to be washed with water, and pressed, till it ceases to dissolve anything; then 100 parts of the pressed carrot are to be boiled in water with five parts of bicarbonate of potash; the root is to be again pressed, and the clear solution, which is pectate of potash, is to be decomposed by the addition of a solution of chloride of calcium, which yields by double decomposition an insoluble pectate of lime; this is to be treated with dilute hydrochloric acid, which separates the pectic acid.

Pectic acid has the following properties: it is a colourless jelly, slightly acid, and reddens litmus paper very distinctly. When distilled it yields a product containing much empyreumatic oil, but no trace whatever of ammonia.

It is very little soluble in water, whether hot or cold, and the filtered solution acts less powerfully on litmus than the gelatinous acid. Although it contains so little of the acid, yet the solution becomes gelatinous when alcohol or sugar is added to it; lime or baryta water also occasions precipitation in it.

When gelatinous pectic acid is gently heated with an excess of caustic potash or soda in a platinum crucible, a brown-coloured solution is soon obtained; and when thus evaporated to dryness, the pectic acid is found almost entirely converted into oxalic acid.

The neutral pectates of potash, soda, and ammonia, when dissolved in water, are separated in a gelatinous state from solution by alcohol, sugar, and saline solutions, &c.

Pectic acid is decomposed by sulphuric acid when they are heated together, and nitric acid converts it into mucic and oxalic acid, &c. Most of the stronger or mineral acids also decompose the saline compounds of pectic acid; but this is not the case with the greater number of the vegetable acids.

The substance originally contained in the currants, &c., and from which pectin is supposed to be derived by the influence of acids, has been named *pectose.* This matter is also accompanied by a kind of ferment, called *pectase.* *Parapectin* is produced by boiling a solution of pectin for some hours. *Metapectin* is obtained by the transformation of parapectin in contact with boiling dilute acids. When pectase is added to a solution of pectic acid, a gelatinous body termed *pectosic acid* is formed. *Parapectic acid, metapectic acid,* and *pyropectic acid* are also unimportant derivatives of pectin.

Little is known as to the exact composition of these substances. The following formulæ have been proposed by different investigators, but they are all doubtful:—

Pectin	$\begin{cases} C_{12}H_8O_{10} \\ C_{28}H_{21}O_{24} \\ C_{64}H_{48}O_{64} \end{cases}$
Metapectic acid	$C_8H_5O_7 + 2HO$
Pyropectic acid	$C_{14}H_9O_9$

PECTIN. [PECTIC ACID.]

PECTOSE. [PECTIC ACID.]

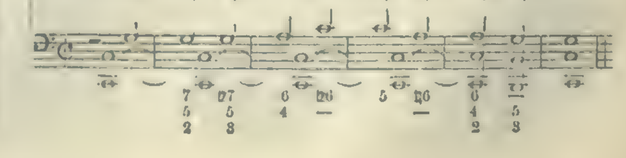
PECTOSIC ACID. [PECTIC ACID.]

PECULIARS, COURT OF, one of the ecclesiastical courts: which, until the abolition of peculiars, took cognisance of all matters arising therein. (Blackst. 'Comm.,' Mr. Kerr's ed., v. iii.)

PEDAL. In musical instruments pedals are of two kinds:—1, those keys which are acted on by the feet of the performer; 2, the levers acting on the swell of the organ, and on the stops; and also those of the pianoforte and harp, the uses of which are too well known to require explanation.

The pedals, or foot-keys, of the organ were invented in the 15th century, by a German named Bernhard; but it was long before they had travelled beyond the confines of the country to which they owed their birth; and strange to say, England was the last to adopt them, though the first to introduce the organ generally into the church. But by slow degrees their utility and importance were discovered and acknowledged, and now no organ, except of small dimensions, is built without these most desirable auxiliaries, and no organist is esteemed who is not tolerably well skilled in the use of them. [ORGAN.]

PEDAL-BASE (or *Pedale*), in music, is a base which remains stationary on one note, while the other parts continue moving and forming various chords, all of which, however, must be related to the holding note, according to the laws of harmony. Example:—



PEDESTAL. [COLUMN.]

PEDIGREE. A pedigree is a tabular view of the members of any particular family, with the relations in which they stand to each other; together, usually, with some slight notice of the principal events of the life of each, as the time and place of birth, marriage, death, and burial, the residence, the profession, or rank of the principal person named in it, and public offices held by him. Sometimes these are accompanied by reference to evidence of the facts stated, as to inquisitions, parish-registers, monumental inscriptions, marriage-settlements, and deeds of all kinds. But when there is much of this kind of information and evidence introduced, the writing is rather called a genealogy, or genealogical history, than a pedigree; and many pedigrees, especially those of early date, are wholly deficient of reference to evidence for proof of the things stated in them, and contain rarely dates or anything more than the mere names of the parties who occur in them. They appear to be the summaries, or things established by certain evidences which may or may not now accompany them, in respect of descents and relationships.

Some fanciful explanations have been given of the word. But perhaps the true etymology may be that which refers it to the Latin *pedes graduum*, the word *pes*, or *pedes*, being much used in the law Latin of the middle ages to denote *summaries*, or the ultimate result in any transaction, as in *pedes finium* and *pedes compoti*. So that a pedigree is, as it were, a *total* of information or evidence respecting descents and kindredships.

The Scripture genealogies, as they are called, are so many pedigrees, but with this difference from the proper idea of a pedigree, that they are not tabular, but narrative.

Tabular genealogies, or pedigrees properly so called, are not of very frequent occurrence in the writings of the middle ages. But they are sometimes found in public records, and in the evidences of private families, or entered in the chartularies of the monastic foundations. They are generally short, containing for the most part only such matter as was wanted for the exhibition of some particular claim of right. But at about the beginning of the 16th century, when the College of Heralds began to pay more attention to the genealogy of the English families in reference to their claims to dignities and to the distinction which the right to armorial insignia gives, many pedigrees were compiled, and in the course of that century the heralds obtained copies of all such accounts of the English families of any distinction as could be supplied to them, and made such accounts matter of public record by entering them in the books which contain the record of their official proceedings. To obtain information of this kind, it was the practice of the heralds of that century, and it continued to be their practice till about the year 1680, to visit the various counties of England from time to time in turn, and to collect from the mouths of the principal persons of each county what they knew of the changes which had taken place in the family since the time of the preceding visitation, or what account could be given of themselves by families who had recently stepped into the rank of gentry, or who had become recently settled in the county. The pedigrees thus collected are in the visitation books at the College of Arms, and form a vast body of this species of information highly important to those who are studying critically the biography of the distinguished persons of the English nation.

Besides this grand collection of pedigrees, there are many similar collections made by private persons, or by the heralds themselves in their private capacity. Many such collections are in the library of the Heralds' College; others are in the British Museum; others in the hands of private persons. Copies of the visitation books are also often to be found. The largest collection of copies is in the British Museum, though copies of some of the best visitation books are not in any of the collections in that depository. There are many copies in the libraries of Queen's College, Oxford, and Caius College, Cambridge.

Since the visitations were discontinued, there has been no official and regular collection of pedigrees. But there has been a continual addition made to the pedigrees which are on record in the visitation books by the entry in the books of the Heralds' College of their pedigree by particular families. In some cases, as of peers, this is compulsory. When arms are granted or dignities conferred, it has been usual for families to record in the college what they know of their descents and alliances. But the books are open to any private family, who may, at a moderate expense, enter a pedigree showing the existing state of the family, and whatever is within the recollection of the older members of it, or can be proved by sufficient evidence. The entries thus officially made are matter of record, and contain information which is often very interesting to the posterity of the persons who occur in them, and may be of importance in protecting rights which belong to them.

The authors of the books of topography have done something to supply the loss of information of this kind which has been sustained by the disuse of visitations, such works usually containing notices of the families who have possessed the more important interests in the district to which the work relates.

PEDIMENT. [GRECIAN ARCHITECTURE.]

PEDLAR. This word is said by Dr. Johnson to be a contraction from *petty dealer*, formed into a new term by long and familiar use; and a pedlar is defined by him to be "one who travels the country with small commodities." The same writer defines a *hawker* to be "one who sells his wares by proclaiming them in the street." In legal understanding however a hawker is an itinerant trader, who goes about from place to place, carrying with him and selling goods; and a pedlar is only a hawker in small wares. In the various acts of parliament which impose duties upon them and regulate their dealings, they are always named in conjunction as hawkers and pedlars; and no distinction is made between them.

It has been for more than a century the policy of English law to consider the conduct of trade by means of fixed establishments as more beneficial to the public than that of itinerant dealers; and it cannot be denied that the local trader being better known and more dependent upon his character than one who continually travels from place to place, there is a greater security for the respectability of his dealings. In conformity with this policy, statutes have been passed from time to time, obliging hawkers and pedlars to take out licences and to submit to specific regulations and restrictions, which are supposed to protect the resident trader as well as the public from unfair dealing. These reasons however have been given *ex post facto* to justify the laws; for the statutes which originally required licences for hawkers and imposed these duties appear to have merely contemplated a means of increasing the revenue. (8 & 9 Wm. III., c. 25; and 9 & 10 Wm. III., c. 27.)

The provisions by which the licences to hawkers and pedlars are now regulated are contained in the statute 50 Geo. III., c. 41; and the Amendment Act 52 Geo. III., c. 108. The duty of granting licences to hawkers and pedlars and enforcing the law against such persons is now entrusted to the commissioners of stamps, under the 1 & 2 Wm. IV., c. 22; the particular conditions and regulations under which such licences are to be granted being contained in the above-mentioned statute, 50 Geo. III., c. 41.

Before a licence is granted to a person desirous of trading and travelling as a hawker or pedlar, the applicant must produce to the commissioners of stamps a certificate, signed by the officiating clergyman and two householders within the parish in which he resides, attesting that he is of good character and a fit person to be licensed. Upon this certificate being given, the commissioners grant the licence, which is only in force for one year, and the party who receives it is subject to a duty of 4*l.* per annum, if he travels on foot or with horses alone, and an additional duty of 4*l.* per annum if he travels with a "horse, ass, mule, or other beast bearing or drawing burthen;" and these duties are to be paid at the time of receiving the licence. All persons who act as hawkers or pedlars without such a licence are liable to a penalty of 50*l.* Among other regulations, the hawker or pedlar is required by the act to "cause to be written in large legible Roman capitals, upon the most conspicuous part of every pack, box, bag, trunk, case, cart, or waggon, or other vehicle in which he carries his goods, and of every room and shop in which he trades, and likewise upon every handbill or advertisement given out by him, the words 'Licensed Hawker,' together with the number, name, or other mark of his licence;" and in case of his omission so to do, he is liable to a penalty of 10*l.*; and every unlicensed person who places these words upon his goods is liable to a penalty to the like amount. A hawker and pedlar travelling without a licence, or travelling and trading contrary to or otherwise than is allowed by the terms of his licence, or refusing to produce his licence when required to do so by inspectors appointed by the commissioners, or by any magistrate or peace-officer, or by any person to whom he shall offer goods for sale, is liable in each case to a penalty of 10*l.* A person having a licence, and hiring or lending it to another person for the purpose of trading with it, and also the person who so trades with another's licence, are each liable to a penalty of 40*l.* A hawker or pedlar dealing in or selling any smuggled goods, or knowingly dealing in or selling any goods fraudulently or dishonestly procured, forfeits his licence, and is for ever afterwards incapacitated from obtaining or holding a new licence. By the stat. 48 Geo. III., c. 84, s. 7, if any hawker or pedlar shall offer for sale tea, brandy, rum, Geneva, or other foreign spirits, tobacco, or snuff, he may be arrested by any person to whom the same may be offered, and taken before a magistrate, who may hold him to bail to answer for the offence under the excise laws.

By the stat. 6 Geo. IV., c. 80, any person hawking any spirits may be arrested, and upon conviction before a magistrate, incurs a forfeiture of the spirits, and may be sentenced to pay a penalty of 100*l.*, and in default to undergo three months imprisonment with hard labour.

By the provisions of the statutes 29 Geo. III., c. 26, s. 6, and also of 50 Geo. III., c. 41, s. 7, no person coming within the description of a hawker or pedlar can lawfully, either by opening a shop and exposing goods to sale by retail in any place in which he is not a householder or resident, other than in a legally established public market during market hours, or by any other means, sell goods either by himself or any other person by outcry or auction, under a penalty of 50*l.*

It is further provided by the 18th section of the 50 Geo. III., c. 41, that, if any person shall forge or counterfeit any hawker's or pedlar's licence, or travel with, or produce, or show any such forged or counterfeited licence, he shall forfeit the sum of 300*l.*

PEERS OF THE REALM are persons to whom the law and constitution attribute certain high dignities and privileges. Without meaning to decide the question whether lords spiritual are in strictness peers of the realm, the persons who fall under this description are the dukes, marquesses, earls, viscounts, and barons, and this without reference to the accident of age, an earl being as much a peer of the realm, though a minor, and consequently not admissible to some of the high privileges of his order. Ladies may also in certain cases be peeresses of the realm in their own right, as by creation, or as inheritors of baronies which descend to heirs general. The wives of peers are peeresses of the realm, and entitled, in consequence of the rank, to certain privileges.

Under the several articles Duke, Marquess, Earl, Viscount, and especially Baron, will be found certain observations pertaining to each distinct order of peers. On the remote origin of this order, and of the privileges belonging to it, especially that great privilege of forming a distinct and independent branch of the legislature, and being at the same time the highest and last court of appeal, great obscurity rests, as it does indeed on the whole of the early constitution and history of Parliament. [Parliament.] The reports of the committee of the House of Peers, which sat during several parliaments about the years 1817, 1818, and 1819, on the dignity of a peer of the realm, contain a great amount of information on these topics, but leave undecided some of the more important questions connected with it.

It is now, however, clearly established, as a part of the laws and constitution of the realm, that every peer, of full age and of sound mind, is entitled to take his seat in the House of Peers and to share in all the deliberations and determinations of that assembly; and that he has privilege (perhaps not very distinctly defined) of access to the king or queen regnant to advise concerning any matter touching the affairs of the realm. These are great and eminent privileges, but they are accompanied by others which illustrate the great consequence and deference which the constitution of England allows to the possessors of this dignity. If charged with any crime, they are not subject to the ordinary tribunals, but the truth shall be examined by the peers themselves; they cannot be arrested in civil cases; a peer's affirmation on honour is sometimes accepted where in ordinary cases an oath is required; and scandals concerning them are peculiarly punishable.

It is now also clearly established that the crown may at its pleasure create a peer—that is, advance any person to the dignity, and to any one of the five orders; but that when once advanced the peer cannot be deprived of the dignity, or any of the privileges connected with it, except on forfeiture of the dignity in due course of law; and the dignity must descend, on his death, to others (as long as there are persons within the limitation of the grant), with all the privileges appurtenant to it, usually to the eldest son, and the eldest of that eldest son in perpetual succession, and so on, to the eldest male representative of the original grantee. Some deviation from this rule of descent, however, has occasionally occurred, special clauses having been introduced into the patent, which is the writing by which the crown declares its will in this particular, limiting the descent of the dignity in a particular way, as in the case of the creation of Edward Seymour to the dukedom of Somerset, in the reign of Edward VI., when it was declared that the issue of the second marriage of the duke should succeed to the dignity in preference to the son of a former marriage. But generally, and perhaps universally for the two last centuries, the descent of a dignity has been limited to the next male heir of the blood of the person originally ennobled; sometimes with remainders to the next male heir of his father or grandfather. There is an instance in the reign of Charles I. of a dignity of peer of the realm being granted to a person (a Lucas) and the heirs male of his body, with remainder to a brother and the heirs male of his body, with remainder to one who was an illegitimate son of the father of the grantee, and therefore, in the eye of the law, not of the blood of the grantee and the heirs male of his body.

It has not unfrequently happened that the crown has granted the dignity of the peerage to a person, with remainder to the female issue or to the female kindred of the grantee and their heirs, as in the case of the Nelson peerage. In these cases it has generally happened either that the party had no male issue to inherit, and that the other males of the family were also without male issue, or that there was already a dignity inheritable by the male heir of the party on whom a new dignity was conferred to descend to his female issue.

The peers who possess what are called baronies in fee are the descendants and representatives of certain old families for the most part long ago extinct in the male line, but which had in their day summons to parliament as peers, and whose dignity it has been assumed descended like a tenement to a daughter, if only one daughter and heir, or to a number of daughters as co-heirs, when there was no son. This principle has been so often recognised, that it may be regarded as a part of the constitution of the peerage; and in virtue of it, if A die seised of a barony in fee, leaving B a daughter and only child and M a brother, the dignity shall inhere in B in preference to M, and shall descend on the death of B to her eldest son. In case A, instead of leaving B his only daughter, leave several daughters, B, C, D, &c., and no son, the dignity shall not go to M, but among the daughters; and since it is imparticipable, it is in a manner lost as long as those daughters, or issue from more than one of them, exist. But should those daughters die with only one of them having left issue, and that issue a son, he shall inherit on the death of his aunts. This is what is meant by the dignity of a peer of the realm being *in abeyance;* it is divided among several persons, not one of whom possessing it wholly, none of them can therefore enjoy it. [Parceners.] But the crown possesses the power of determining the abeyance; that is, it may declare its pleasure that some one of the daughters, or the eldest male representative of some one of the daughters, shall possess the dignity, as would have been the case had there been a single daughter only; and in case of an heir thus entering into possession of the dignity, he shall take that precedence among the barons in the House of Peers which belonged to the family of whom he is the representative. A female who is only a co-heir of a co-heir may also have the abeyance determined in her favour.

Many of the peers, having a superior title limited to heirs male, have baronies in fee inherent in them; so that if A, one of them, die, leaving a daughter, an only child, and a brother, the brother shall take the superior title, and the barony descend to the daughter and the heirs of her body. An eldest son of a peer enjoying a barony and a superior dignity is sometimes also called to the House of Peers in his father's barony. When this is done, it is by writ of summons without a patent of creation (it not being in fact a creation of a new dignity, but only in anticipation of the son's possession of it), and this is the case also when a barony is taken out of abeyance.

Thus the English portion of the House of Peers, or House of Lords, for they are terms used in precisely the same sense, are the lords spiritual—that is, the archbishops and bishops—and the lords temporal, who are of one of the five orders (though many of the dukes possess dignities of the four inferior kinds also, and their ancestors may have long had seats in that house in those inferior dignities before the family was raised to the dukedom), and these are either persons who have been created peers by the crown, who have been admitted into the peerage by favour of the crown in virtue of the determination of an abeyance, or who have inherited the dignity from some ancestor on whom it had been conferred.

The fullest information on all points connected with the antiquarian part of this subject is to be obtained from the Reports of the Committee of the House of Lords before referred to. Biographical accounts of the more eminent of the persons who have possessed these dignities are to be found in that very valuable book, Dugdale's 'Baronage of England.' In 1708, Arthur Collins, a London bookseller, published in a single volume an account of the peers then existing and their ancestors, a work of great merit. The demand for it appears to have been great, as it was followed by other editions in quick succession. It assumed a higher character in 1734, when it appeared in four octavo volumes, great additions having been made to every article. From that time there has been a succession of editions, each professing to be improvements on the preceding, and each bringing up the state of the peerage to the time when the work was printed. But as titles become extinct, and consequently the families bearing them are left out of the peerage-books, those who wish to possess a complete account of those eminent persons must procure many of the earlier editions of the work, as well as that which, being the latest, will for the most part be called the best. There are certain minor works giving the genealogical details of the descent of the dignities, which are published almost every year; but they do not possess the authority of the older works, being too courtly in the manner of their compilation to state the *whole* truth.

PE'GASUS, one of the old constellations, called by Aratus (and also by Hyginus) simply the Horse. The mythological accounts of Pegasus (a son, it was said, of Neptune and the Gorgon Medusa, though how with such parentage he came to be a horse is not stated), the creator of the fountain Hippocrene at one kick, are more than usually unconnected, and the constellation is not a whole horse, but only the head, fore legs, and shoulders, to which a pair of wings is attached; nor is there any fountain near the place, except that with which Aquarius feeds one of the fishes. The figure of Pegasus is inverted, the head being farther from the north pole than the body: the constellation is surrounded by Cygnus, Equuleus, Aquarius, Pisces, and Andromeda. There are three bright stars, α (or Markab), β (or Scheat), γ (or Algenib), which form a rectangular figure with α Andromedæ, such as cannot be mistaken when the latter constellation is known. Moreover a line drawn through α and β points to the pole star, in a line which produced passes through the pointers of the Great Bear.

The following are the principal stars:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.

β	53	8032	2
α	54	8034	2
γ	88	26	2

PEINE FORTE ET DURE. The "strong and hard pain," which is denoted by these words, was a species of torture used by the English law to compel persons to plead when charged judicially with crimes less than treason, but amounting to felony. It was applicable whenever the accused stood mute on his arraignment, either by his refusal to put himself upon the ordinary trial by jury, or to answer at all, or by his peremptorily challenging more than twenty jurors, which was a contumacy equivalent in construction of law to actually standing mute. This proceeding differed essentially from the "quæstio" in the Roman law, and the torture which generally prevailed in Europe, and which, as connected with the royal prerogative, was also practised in England for several centuries, inasmuch as its object was to force submission to the regular mode of trial prescribed by the law, and not to compel testimony or the confession of a crime.

Much difference of opinion has existed upon the question whether the practice of the peine forte et dure originated with the statute usually called the Statute of Westminster 1 (3 Edw. I., c. 12), or whether it was in use at an earlier period. The latter opinion is maintained by Coke and Hale, but the former is adopted by Staundforde, Blackstone, and Barrington. In a note to Hale's 'Pleas of the Crown,' vol. ii., p. 322, Emlyn says that although the Statute of Westminster 1 speaks of this punishment rather as a thing already known than as a new introduction, there is no notice taken of it in any ancient author, case, or record before the reign of Edward I.; and, on the contrary, he cites two curious records in the reign of Henry III., from which it appears that persons at that time arraigned for felony, and standing mute, were not put to peine forte et dure, but had judgment to be hanged. Upon this point it is worthy of remark that the statute of Edward I. merely directs that "such persons as will not put themselves upon inquests of felonies at the suit of the king shall be put into hard and strong prison (*soient mys en la prisone fort et dure*), as those which refuse to be at the common law of the land;" whereas the judgment of the peine forte et dure, as given in ancient books, contained many particulars of suffering to be imposed on the contumacious prisoner, not mentioned in the statute. Fleta, who must have written about ten years after the date of the statute, describes the judgment to be, that "the party shall be cast into prison and lie upon the bare ground clothed with a single garment and barefooted; that he shall have for his food only three morsels of barley-bread in two days; that he shall not have food every day, but only on alternate days; that he shall not drink every day, but that on the day when he shall have no food, water shall be given him to drink." (Fleta, lib. i. cap. 34.) It certainly seems improbable that all these circumstances should, within a very few years, have been added to the judgment warranted by the statute, if the statute had really been the origin of the practice. Mr. Reeve has plausibly suggested that the only object and effect of the statute was to apply the same compulsory process to those who refused to submit themselves to trial by jury in indictments at the king's suit, which had been previously used to compel persons to put themselves upon ancient methods of inquiry, namely, the duel, the ordeal, or the wager of law. ('Hist. of the English Law,' vol. ii., p. 137.) The trial by jury had no doubt been much encouraged during the reign of Henry III., in opposition to the barbarous modes of trial previously used; and it is therefore by no means improbable that this statute should have contemplated the promotion of this great judicial improvement. The language of the enactment also is entirely consistent with the view of its object suggested by Mr. Reeves. On the other hand it must be acknowledged that the instances above mentioned, as cited by Emlyn, and the total silence of Glanville and Bracton, as well as of the judicial records anterior to the statute, respecting such a mode of enforcing submission to the law, are adverse to this interpretation. The origin of this rude proceeding must therefore be considered as uncertain.

It appears from Fleta, and also from Britton (c. 22), that the punishment in the reign of Edward I., when the first traces of it in the history of English law appear, consisted merely of severe imprisonment, with a diet barely sufficient to prevent starvation, until the offender repented of his contumacy and consented to put himself upon his trial. A curious charter of pardon in 1357 ('Fœdera,' vol. vi. p. 13), recites that a woman indicted for the death of her husband, having stood mute, had been adjudged "ad pœnam suam, ut dicitur, in quâ sine cibo et potu in artâ prisonâ per quadraginta dies vitam sustinuit viâ miraculi et quasi contra naturam humanam." It appears therefore that at that time the sentence continued to be imprisonment only, and did not authorise the infliction of any further violence. Shortly afterwards, however, the practice of loading the sufferer with weights and pressing him to death appears to have become the regular course. In the Year Book of 8 Henry IV. (1406), the judgment upon persons standing mute, as approved by advice of all the judges, was "that the marshal should put them in low and dark chambers, naked except about the waist; that he should place upon them as much weight of iron as they could bear, *and more*, so that they should be unable to rise; that they should have nothing to eat but the worst bread that could be found, and nothing to drink but water taken from the nearest place to the gaol, except running water; that the day on which they had bread they should not have water, and *e contrà*; and that they should lie there till they were dead." Thus, although the reporter states in this case that the judgment was formally different, the punishment now became capital, a lingering and painful death being enjoined instead of severe imprisonment to extort submission. There is no trace of any statute or royal ordinance, or of any authority besides this judicial resolution to justify a change in the mode of proceeding so material as to affect the life of the party. The term by which it was denoted was also changed from *prisone* to *peine* forte et dure; and from this period, for more than three centuries, until it was virtually abolished by the stat. 12 Geo. III., c. 20 (1772), *pressing* to death continued to be the regular and lawful mode of execution for criminals who stood wilfully mute upon their arraignment for felony. The press-yard at Newgate at the present day retains it name as derived from this barbarous practice.

Blackstone, after alluding to "the doubts that were conceived of its legality," and "the repugnance of its theory to the humanity of the laws of England," states that the peine forte et dure was rarely carried into practice. It is probable that it was not of frequent occurrence, because with this fearful punishment for contumacy before their eyes men would naturally for the most part (as Hale says) "bethink themselves and plead." It is, however, repeatedly mentioned in the Year Books as an existing proceeding; it is stated as the law of the land by Staundforde, Coke, Hale, and Hawkins, in their several treatises on the criminal law, and the number of the recorded instances in which it is directly or incidentally mentioned seem to show that it was much more prevalent than has been commonly supposed. The motive of the prisoner in standing mute and submitting to this heavy punishment was to save his attainder, and prevent the corruption of his blood and consequent forfeiture of his lands in case he was attainted of felony. In 21 Hen. VI. (1442), Juliana Quicke, who was indicted for high treason in speaking contemptuous words of the king, had the peine forte et dure because she would not plead (Cro. 'Car.' 118); in the margin of an inquisitio post mortem of Anthony Arrowsmith, in 40 Eliz. (1598), are the words "Prest to death" (Surtees's 'History of Durham,' vol. iii., p. 271); and in 1659, Major Strangeways was tried for the murder of John Fussell before Lord Chief Justice Glynn, and, refusing to plead, was pressed to death in Newgate. In the pamphlet which very minutely relates the particulars of this execution, it is stated that the prisoner died in about eight minutes, many people in the press-yard humanely casting stones upon him to hasten his death. (Barrington's 'Antient Statutes,' p. 85, note.) In still more recent times it appears from the Old Bailey Sessions Papers that at the January Sessions in 1720, one Phillips was pressed for a considerable time, until he begged to stand his trial; and at the December Sessions, 1721, Nathaniel Haws continued under the press with 250 lbs., for seven minutes, and was released upon his submission. Mr. Barrington says that he had been furnished with two instances in the reign of George II., one of which happened at the Sussex assizes before Baron Thompson, and the other at Cambridge, in 1741, when Mr. Baron Carter was the judge. (Barrington's 'Antient Statutes,' p. 86.) In these later instances the press was not inflicted until by direction of the judges the experiment of a minor torture had been tried, by tying the culprit's thumbs tightly together with strings. It is said in Kelyng's 'Reports,' p. 27, to have been the constant practice at Newgate in the reign of Charles II., that the two thumbs should be tied together with whipcord, that the pain of that might compel the culprit to plead. The adoption of this course was no doubt dictated by merciful motives, and was intended by the judges to prevent the necessity of having recourse to the peine forte et dure; but it was wholly unauthorised by law. The practice was finally discontinued in consequence of the statute 12 Geo. III., c. 20, which provides that every person who shall stand mute when arraigned for felony or piracy shall be convicted of the same, and the same judgment and execution shall be awarded against him as if he had been convicted by verdict or confession. But the law in this respect has been altered by the statute 7 & 8 Geo. IV., c. 27, a plea of 'not guilty' being entered on the record if the prisoner refuses to plead.

PELAGIANISM. [PELAGIUS, in BIOG. DIV.]

PELARGONE. [PELARGONIC GROUP.]

PELARGONIC ACID, $C_{18}H_{17}O_3 + HO$, is found in the oil of *Pelargonium roseum*. It is an acid oily liquid, with a rancid smell. It becomes solid at low temperatures, and its salts form soap. It forms a *Pelargonate of the oxide of Ethyl*, $C_4H_5O + C_{18}H_{17}O_3$, which is an oily liquid of a very peculiar smell. Frankland states that whiskey owes its peculiar flavour to the presence of this compound. It is manufactured for the purpose of giving new whiskey the flavour of old. [PELARGONIC GROUP.]

PELARGONIC GROUP. A family of organic substances [PELARGONIC SERIES] derived from a peculiar acid found in geraniums (*Pelargonium roseum*). The following are the names and formulæ of the principal members of this group :—

Pelargonic acid	$C_{18}H_{17}O_3$, HO
Pelargone	$\left.\begin{matrix} C_{18}H_{17}O_2 \\ C_{16}H_{17} \end{matrix}\right\}$
Pelargonic ether	$C_{18}H_{17}(C_4H_5)O_4$
Chloride of pelargyl	$C_{18}H_{17}O_2Cl$
Pelargyl	$C_{18}H_{17}O_2$

PELARGONIC SERIES. A division of organic bodies in Gerhardt's system of classification. It contains the following three groups :—

Octylic group.
Pelargonic group.
Sebacic group.

PELARGO'NIUM, the name of a greenhouse plant, not unfrequently confounded with the geranium. There is a large number of genuine species of this genus, chiefly inhabiting the Cape of Good Hope; and as these intermix very readily, a prodigious number of spurious species, as well as acknowledged varieties, have found their way into the writings of systematic botanists. While however science has been embarrassed by this facility of crossbreeding, the gardens have been enriched by crowds of the most beautiful objects, in which the features of their savage progenitors can no longer be recognised; and it is probable that of all the flowers which have been acted upon by the hand of man, the pelargonium is that in which the result has been most striking. The tuberous-rooted sorts are the most valued for the brilliance of their flowers, and they are propagated either by division of the roots, or by cuttings from the plant. Propagation by seed is resorted to chiefly to obtain varieties, in which the form of the flower, the substance of the petals, and the colour, are the objects aimed at. March is a good time for sowing, which should be done in small pots, in a light rich mould mixed with river sand; and in the division by roots the same method may be followed. With cuttings, from the end of February to the end of August, any time will serve, but in the earlier months the pots should have moderate bottom heat; and in the later, and warmer months, they should be well shaded. The cuttings should be made immediately under a bud, they should be placed near the edge of the pot, gently watered, and guarded against damping off. By care and attention to a few simple points of practice, these plants may be cultivated and multiplied by any one who has a greenhouse, and hence they have become universal favourites. Those points are the following, namely: 1, water, 2, warmth, 3, a gentle bottom heat, 4, abundance of air, 5, as much light as the leaves will bear, and 6, a rich soil during the season of growth; and a cool atmosphere, less water, abundance of light, and close pruning afterwards.

PELARGYL. [PELARGONIC GROUP.]

PELASGI (Πελασγοί) were the most ancient inhabitants of Greece, as far as the knowledge of the Greeks themselves extended; whence they came, or what they really were, is quite unknown. They were one of several races, stated by the Greeks to have been ante-Hellenic, among whom the Leleges are nearest in age and importance to the Pelasgi. The dynasties which include Danaus, Deucalion, and Cadmus, are entirely legendary. There is no doubt there was a people whom the Hellenes styled Pelasgi; but nothing is historically known of them; and it is probable that many of the districts subsequently said to be inhabited by the descendants of the Pelasgi, were merely non-Hellenes, to whom the general term was applied. The whole of Hellas, according to Herodotus (ii. 56), was originally called Pelasgia; and Æschylus ('Supp.,' 250) introduces Pelasgus, king of Argos, as claiming for the people named after him all the country through which the Algus flows, and to the west of the Strymon. We find mention of the Pelasgi in the Peloponnesus, Thracia, Thesprotia, Attica, Bœotia, and Phocis. (Strabo, vii. 321; Herod., viii. 44.) The oracles of Delphi and Dodona were originally Pelasgic (Strabo, ix. 402; vii. 327; compare Herod., ii. 52); and Mr. Clinton ('Fast. Hell.,' vol. i., p. 22) and Niebuhr ('Rom. Hist.' vol. i., p. 27) have adduced reasons for believing that the Macedonians also were a Pelasgic race. We also find traces of the Pelasgi in many of the islands of the Ægean Sea, as Lemnos, Imbros, Lesbos, Chios, &c. (Strabo, xiii. 621); and Herodotus informs us (vii. 95) that the islands were inhabited by the Pelasgic race till they were subdued by the Ionians. The neighbouring coast of Asia Minor was also inhabited in many parts by the Pelasgi. (Strabo, xiii. 621.) The country afterwards called Æolis was occupied by Pelasgians (Herod., vii. 95); and hence Antandros was called Pelasgic in the time of Herodotus (vii. 42). Tralles in Caria was a Pelasgic town (Niebuhr, 'Rom. Hist.,' vol. i., p. 33), and two of their towns on the Hellespont, Placia and Scylace, were still extant in the time of Herodotus (i. 57).

The Pelasgians were also widely spread over the south of Italy; and the places in which they appear to have been settled are indicated by Mr. Malden ('Rom. Hist.') and Niebuhr ('Rom. Hist.').

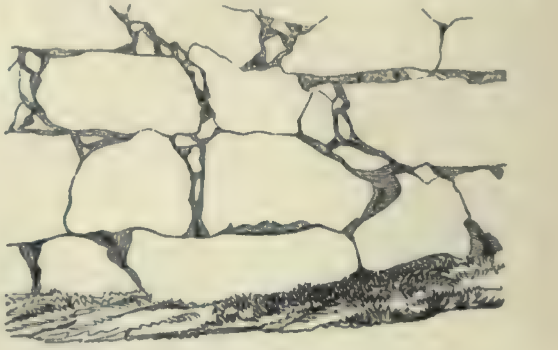
The connection between the Pelasgic and Hellenic races has been a subject of much controversy among modern writers. Many critics have maintained that they belonged to entirely different races, and some have been disposed to attribute to the Pelasgians an Etruscan or Phœnician origin. It is true that many of the Greek writers speak of the Pelasgians and their language as barbarous, that is, not Hellenic; and Herodotus (i. 57) informs us that the Pelasgian language was spoken in his time at Placia and Scylace on the Hellespont. This language he describes as barbarous; and on this fact he mainly grounds his general argument as to the ancient Pelasgian tongue. The ancient writers differ as much respecting the degrees of civilisation which the Pelasgi attained before they became an Hellenic people, as they do respecting their original language. According to some ancient writers (all however only repeating traditions), they were little better than a race of savages till conquered and civilised by the Hellenes; but others represent them, and perhaps more correctly, as having attained a considerable degree of civilisation previous to the Hellenic conquest. Many traditions represent the Pelasgians as cultivating agriculture and the useful arts; and a modern writer (Thirlwall, 'Greece,' vol. i., p. 39) rather fancifully supposes that the most ancient form of their name (Πελασγοί) signified inhabitants or cultivators of the plain.

Some writers have maintained that the Greeks derived the art of writing and most of their religious rites from the Pelasgians; but without entering into these questions, it may be asserted with some degree of certainty that the most ancient architectural monuments in Europe clearly appear to have been the works of their hands; that is, of a race older than the Hellenes. [PELASGIAN ARCHITECTURE.]

(Marsh's *Horæ Pelasgicæ*; Niebuhr's *Hist. of Rome*; Thirlwall's *Hist. of Greece*; Clinton's *Fasti Hellenici*; Grote's *History of Greece*; Wachsmuth's *Hellenische Alterthumskunde*).

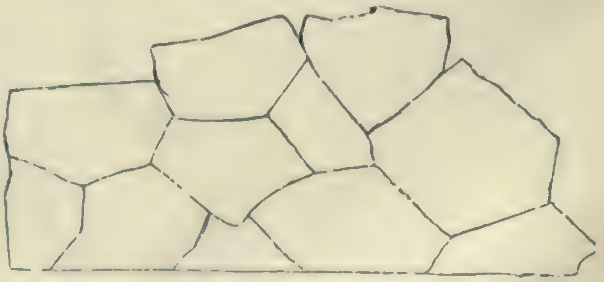
PELASGIAN ARCHITECTURE. The vast masses of unhewn and uncemented masonry forming the walls of Tiryns,—the ancient Tirynthus, about two miles from Nauplia, on the road to Argos,—the oldest human constructions in Greece, were by ancient tradition attributed to the fabulous Cyclopes. They, and similar masses of masonry, have hence come to be generally termed Cyclopean. There can be little doubt that they are of pre-historic date; but they are most probably of Pelasgic origin: the oldest examples of a mode of construction which is found not only in various parts of Greece, but on the western coasts of Asia Minor and in Italy,—wherever, in fact, the Pelasgi settled. [PELASGI.] According to Greek tradition, the walls of Tiryns were built by the Cyclopes for Proetus, as a protection from the attacks of Acrisius; and the date has been, with a vain affectation of precision, fixed at 1379 B.C. All that can with confidence be said of these walls is, that they were in existence when Homer wrote, since he designates Tirynthus as the "well-walled" (Τίρυνθά τε τειχιόεσσαν, 'Il.' ii. 559); and from the mention of them by later Greek writers, and their character, there cannot be any doubt that the existing remains are a portion of the walls referred to by Homer.

The distinguishing character of the walls of Tiryns (and similar walls occur in Lycia), is that they are built of immense polygonal blocks of stone, irregular in size and form, which are laid together with a certain amount of art, and are held in their places by their own weight, no cement of any kind having been employed to fasten them: the interstices between the large blocks are filled by smaller pieces. Some of the largest stones are 9 feet long, 4 feet wide, and nearly as deep; but a more common size is 7 feet by 3 feet.



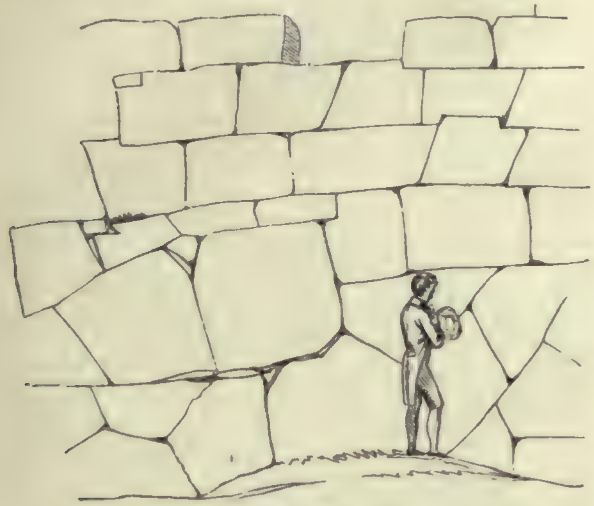
Wall of Tiryns.

At Mycenæ, about 12 miles from Nauplia, are extensive walls of a similar character, and which, like those of Tiryns, were also said by the ancient Greeks to be the work of the Cyclopes; but they, as well as those at Epirus, are obviously of a later date than those of Tiryns, on which they are a marked improvement. In this case, though the blocks are still large, irregular, polygonal masses, they are fitted carefully to each other, and present a smooth exterior surface.



Walls of a Temple at Epirus.

Walls of this kind are found in many parts of Greece, and are of great antiquity. Mycenæ was designated the "well-built" by Homer; but its massive walls were neglected and ruinous when Pausanias and even when Thucydides wrote. A later and more improved style of Pelasgian masonry is that seen in many of the older fortified portions of Greek cities, and in some of the cities of Etruria. In this mode the blocks are still irregular in size, and more or less polygonal, but they are laid with an approximation to horizontality. From this the next step was comparatively easy to the so-called Cyclopean masonry of the ancient Etrurians, which consisted of squared blocks laid without cement in horizontal courses. [ETRUSCAN ARCHITECTURE.] The walls of Cosa, near Orbitella, afford a good example of the latest form of Pelasgic masonry, with, in the upper part, the earliest Etruscan. Cosa, there can be little doubt, was a Pelasgian city before it was colonised by the Etruscans.



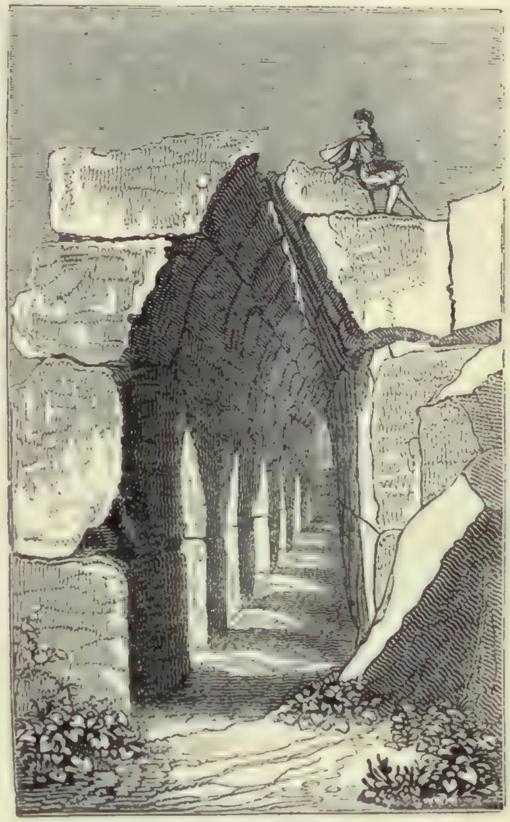
Walls of Cosa.

Of Pelasgian buildings, properly so called, the examples remaining are few, and comparatively unimportant. Of their palaces, which judging from Homer's description of that of Odysseus, and indications in other early writers, must have possessed a certain amount of splendour, no remains exist. They were probably built for show rather than permanency, and may, as has been conjectured, have been constructed chiefly of wood: at any rate they have long perished. Nor are any temples or religious edifices extant. The most remarkable of the existing structures are the subterranean domed buildings called treasuries, but which were more probably tombs, of which that at Mycenæ is the oldest and most important example. This is now usually called the Treasury of Atreus; but its local name appears to be the Tomb of Agamemnon. Constructed under the slope of a hill, the approach to it is by a passage 20 feet wide. The doorway was flanked by highly ornamented semi-columns, portions of which still remain. The interior consists of two domicular chambers. The dome of the largest is 47 feet 6 inches in diameter, and 50 feet high. A doorway leads from it to a smaller chamber, which is about 23 feet in diameter. The domes are formed by horizontal courses of stones, each course projecting beyond that beneath. The walls, of course, gradually approach towards the top, which is closed by a large single slab, thus forming an equilateral pointed instead of a semicircular vault. These are the largest structures of that kind known. The walls of the larger chamber have numerous nail-holes, in horizontal rows, and near the apex of the dome several nails still project from the surface. These are believed to be the fastenings of the brazen plates with which the walls were covered: this being probably one of those "brazen chambers" of which mention is frequently made by Greek writers. The entrance doorway, like nearly all Pelasgian doorways, is formed by two large upright blocks of stone, or jambs, which incline slightly inwards towards the top, and a larger block, or lintel, laid on them. The opening is 18 feet high, 11 feet wide at bottom, and somewhat less at top; the lintel is formed by a block of stone 27 feet long and 16 broad. Over the doorway is a triangular opening. The façade was ornamented with semi-columns and slabs of coloured marbles, with peculiar zigzag carvings in an essentially Oriental style. The characteristic Ionic scroll also occurs. Two similar but smaller and less elaborate structures occur at Mycenæ. Remains of another, known as the Treasury of Minyas, are found at Scripu, the site of the Bœotian Orchomenos; and others in a more or less perfect condition elsewhere.

The walls of Tiryns, of which we spoke above, were a part of the original fortifications, a branch of engineering in which the Pelasgi attained remarkable proficiency, and they are the best remaining example of the fortifications of the heroic ages.

The fortifications occupied the summit of a rocky height (the Acropolis) and covered an area of 660 feet by 180. The walls are in places above 20 feet high, but have been higher; their average thickness is 25 feet. According to Colonel Leake "the fortress appears to have consisted of an upper and lower enclosure, of nearly equal dimensions, with an intermediate platform, which may have served for the defence of the upper castle against an enemy in possession of the lower one."

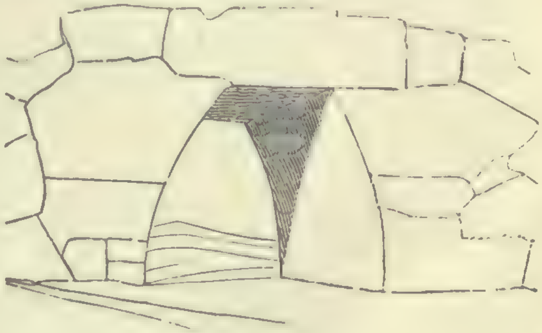
Besides the principal entrance, which was reached by a zig-zag flight of steps, there were postern gates; passages connected the upper and lower fortresses, and there were semicircular bastions and projecting defences with retirements in the walls which served to cover the approaches. But the most remarkable constructive features remaining are galleries formed in the walls; that in the eastern wall consisting of two parallel passages, the centre of which has six recesses or niches in the exterior wall.



Gallery at Tiryns.

"These niches," says Colonel Leake, who brought to his examination of the fortifications professional as well as archæological knowledge, "were probably intended to serve for the defence of the galleries; and the galleries for covered communications to towers or places of arms at the extremity of them. One of these still exists at the south-west angle." These galleries, it will be observed, were formed by making the courses of stones project over each other, the curved form of a pointed arch being given by cutting the inner surface of the projecting stones.

Openings of this form are frequent in doorways and in Pelasgic remains in Italy, as well as in Greece, though no example of a true arch occurs. We give an illustration from Segni in Latium.



Walls and Gateway at Segni.

The fortifications at Mycenæ are even more remarkable from their extent than those at Tiryns. Their builders, as has been mentioned, were said to be the Cyclopes; they were destroyed as far as they could be destroyed by the Argives, 466 B.C. What remains of them consists of an irregular enclosure above 1000 feet long by nearly 700 broad, and in some places 20 feet high. As has been said, the walls exhibit an improvement in structure over those of Tiryns; but the fortifications themselves it is scarcely necessary to say present no architectural character. The only ornamental feature is the great gateway, which is 10 feet high, and at the top 9½ feet wide. It is formed by two great stone uprights or jambs, covered with a lintel 15 feet long, 4 feet wide, and 6 thick. The lintel bears marks of bolts and hinges, and on clearing away the ground in 1842, the ruts formed by the chariot wheels were found in the smooth slabs of the pavement. Above the lintel is a block of gray limestone, 10 feet high and 12 wide, upon which, sculptured in low-relief, is a central column or altar with, on each side, a lion standing on his hind legs and resting his fore-paws on the base; whence it is known as the Gate of the Lions. This is the oldest known example of sculpture in Greece. Pausanius mentions this gateway (B. ii. c. 16) which, he adds, they report was made by the Cyclopes. The lions are carved in a rude but simple style; and in the frieze or altar borne by the central column are rude circular projections which Mr. Fergusson believes represent "the round ends of the timbers of the roof, as if projecting into the frieze."

By the Lernean Marsh, about half a mile from the road from Argos to Mantinea, and a mile from the Erasinos, are the remains of a pyramid crowning a rocky eminence, which some have supposed to be of Pelasgic construction. It is doubtless of extreme antiquity, but whether Pelasgic or not is uncertain: some have seen in it a connecting link with the mythic Egyptian colony of Danaus.

(Leake, *Travels in the Morea*; *Peloponnesiaca*; Mure, *Tour in Greece*; Sir W. Gell, *Argolis*; Pouqueville, *Voyage dans la Grèce*; Petit-Radel, *Recherches sur les Monumens-Cyclopéens*; Donaldson, *Antiquities of Athens.*)

PELLA'GRA is a disease chiefly affecting the skin, and particularly prevalent amongst the peasantry of the north of Italy. According to Dr. Holland (whose description in the 8th volume of the 'London Medico-Chirurgical Transactions,' is by far the best that has been published in this country), the disease affects the poor almost exclusively, and among them chiefly those who are occupied in the culture of the irrigated rice-grounds, and in other branches of agricultural labour. It usually appears first as a disease of the skin, breaking out early in the spring, with slightly elevated shining dark-red blotches on the hands and feet, and sometimes on other parts of the body, accompanied by a slight pricking sensation. Soon after, small tubercles arise upon the inflamed blotches, and the skin becomes dry and scaly, and often deeply cracked. Desquamation gradually takes place, and, towards the close of the summer, or even earlier, the skin usually appears quite recovered. This, at least, is the usual progress of the first attack; and there is seldom any greater general disturbance of the health than debility, irregular pains of the body, loss of appetite, and emaciation.

In the next spring however the disease usually recurs, with a great aggravation of both the local and the general symptoms, and especially with an increase of the nervous affection, and great anxiety and despondency. In succeeding years it regularly returns with increased severity in every spring, though it does not, as at first, leave the patient nearly healthy in the autumn and winter. After the third attack, or sometimes later, the weakness of the patient commonly becomes extreme, and he has many symptoms similar to those of scurvy, with constant diarrhœa, dropsical swellings, and various nervous disorders. Its most marked character however is the total despair which fills the patients' minds, from which nothing can rouse them, and which, if the disease does not prove fatal by its effects in debilitating their bodies, generally leads to incurable idiotcy or mania. In the lunatic hospital at Milan, Dr. Holland found, among 500 patients, more than one-third in whom the insanity had been the result of pellagra, and "even this statement gives little adequate idea of the nature of its ravages. The public hospitals are far from sufficient to receive the vast number of persons affected with the pellagra; and the greater proportion perish in their own habitations, or linger wretched spectacles of fatuity and decay." The period during which the disease may continue is uncertain; but after the third or fourth year, there is usually little hope of benefit from any means that can be adopted. The diseases to which, in its later stages, it may lead, or with which it may be complicated, are of the most varied kinds; and there are few which, in different cases, the Italian physicians do not ascribe to its influence.

The pellagra prevails chiefly in the provinces of Lombardy between the Alps and the Po, and especially in the district between the Lago Maggiore and the Lago di Como. Among the inhabitants of these parts it has now been supposed to have existed for upwards of a century: here it appears first to have become an object of attention to physicians, and hence to have spread slowly to the Venetian and other northern provinces. It is distinctly an hereditary disease; but there is no sufficient evidence for believing it to be propagated by contagion. Its origin and prevalence are rather to be referred to the condition of poverty in which the peasantry, though the cultivators of one of the most fertile countries in Europe, are compelled to live. Their ordinary diet consists of vegetables, which are usually of inferior quality and ill-prepared: their bread, which is principally made of maize, is for the most part ill-fermented, and often deficient in salt. They rarely have any animal food, and their poverty almost entirely precludes the use of the wines of their own country. Similar wretchedness is evident in their clothing, in their dwellings, and in the deficiency of all the commonest comforts of life. They are thus constantly predisposed to the attacks of diseases of all kinds, and especially are unfit for exposure to the influence of a burning sun during severe agricultural labour. Hence the disease usually makes its first appearance when the peasants are at their most active work, and when the heat of the days is increasing; and hence it is usually first characterised by a disease of the skin, which however is but a slight indication of its future more serious and varied effects.

The treatment of pellagra offers little prospect of success, so long as the patient remains exposed to the same influences by which he was rendered subject to its attack. The course usually adopted by the Italian physicians for the patients who are admitted into the hospitals is a liberal allowance of wholesome food, and the administration of wine and of tonics of various kinds. There seems little reason to doubt that if wholesome food could be constantly secured for the poor, the pellagra would speedily disappear from all the districts in which it now so fatally prevails.

PELLUTEINE. [Pelosine.]

PELOPONNESIAN WAR is the name given to the great contest between Athens and her allies on the one side, and the Peloponnesian confederacy, headed by Sparta, on the other, which lasted from 431 to 404 B.C. The political state of Greece at the commencement of the war has been briefly described under Greece, in Geog. Div. The war was a consequence of the jealousy with which Sparta and Athens regarded each other, as states each of which was aiming at supremacy in Greece, as the heads respectively of the Dorian and Ionian races, and as patrons of the two opposite forms of civil government, oligarchy and democracy. The war was eagerly desired by a strong party in each of those states; but it was necessary to find an occasion for commencing hostilities, especially as a truce for thirty years had been concluded between Athens and Sparta in the year B.C. 445. Such an occasion was presented by the affairs of Corcyra and Potidæa. In a quarrel which soon became a war between Corinth and Corcyra, respecting Epidamnus, a colony of the latter state (B.C. 436), the Corcyreans applied to Athens for assistance. Their request was granted, as far as the conclusion of a defensive alliance between Athens and Corcyra, and an Athenian fleet was sent to their aid, which however soon engaged in active hostilities against the Corinthians.

Potidæa, on the isthmus of Pallene, was a Corinthian colony, and even after its subjection to Athens continued to receive every year from Corinth certain functionaries or officers (*ἐπιδημιουργοί*). The Athenians, suspecting that the Potidæans were inclined to join in a revolt to which Perdiccas, king of Macedon, was instigating the towns of Chalcidice, required them to dismiss the Corinthian functionaries, and to give other pledges of their fidelity. The Potidæans refused, and, with most of the other Chalcidian towns, revolted from Athens, and received aid from Corinth. The Athenians sent an expedition against them, and, after defeating them in battle, laid siege to Potidæa (B.C. 432).

The Corinthians now obtained a meeting of the Peloponnesian confederacy at Sparta, in which they complained of the conduct of Athens with regard to Corcyra and Potidæa. After others of the allies had brought their charges against Athens, and after some Athenian envoys, who happened to be in the city, had defended the conduct of their state, the Spartans first, and afterwards all the allies, decided that Athens had broken the truce, and they resolved upon immediate war: king Archidamus alone recommended some delay. In the interval necessary for preparation, an attempt was made to throw the blame of commencing hostilities upon the Athenians, by sending three several embassies to Athens with demands of such a nature as could not be accepted. In the assembly which was held at Athens to give a final answer to these demands, Pericles, who was now at the height of his power [Pericles, in Biog. Div.], urged the people to engage in the war, and laid down a plan for the conduct of it. He advised the people to bring all their moveable property from the country into the city, to abandon Attica to the ravages of the enemy, and not to suffer themselves to be provoked to give them battle with inferior numbers, but to expend all their strength upon their navy, which might be employed in carrying the war into the enemies' territory, and in collecting supplies from the subject states; and further, not to attempt any new conquest while the war lasted. His advice was adopted, and the Spartan envoys were sent home with a refusal of their demands, but with an offer to refer the matters in difference to an impartial tribunal, an offer which the Lacedæmonians had no intention of accepting. After this the usual peaceful intercourse between the rival states was discontinued.

Thucydides (ii. 1) dates the beginning of the war from the early spring of the year 431 B.C., the fifteenth of the thirty years' truce, when a party of Thebans made an attempt, which at first succeeded, but was ultimately defeated, to surprise Platæa. The truce being thus openly broken, both parties addressed themselves to the war. The Peloponnesian confederacy included all the states of Peloponnesus, except Achæa (which joined them afterwards) and Argos, and without the Peloponnesus, Megaris, Phocis, Locris, Bœotia, the island of Leucas, and the cities of Ambracia and Anactorium. The allies of the Athenians were Chios and Lesbos, besides Samos and the other islands of the Ægean which had been reduced to subjection (Thera and Melos, which were still independent, remained neutral), Platæa, the Messenian colony in Naupactus, the majority of the Acarnanians, Corcyra, Zacynthus, and the Greek colonies in Asia Minor, in Thrace, and Macedonia, and on the Hellespont. The resources of Sparta lay chiefly in her land forces, which however consisted of contingents from the allies, whose period of service was limited; the Spartans were also deficient in money. The Athenian strength lay in their fleet, which was manned chiefly by foreign sailors, whom the wealth that they collected from their allies enabled them to pay.

Thucydides informs us that the cause of the Lacedæmonians was the more popular, as they professed to be deliverers of Greece, while the Athenians were fighting in defence of an empire which had become odious through their tyranny, and to which the states which yet retained their independence feared to be brought into subjection.

In the summer of the year 431 B.C., the Peloponnesians invaded Attica under the command of Archidamus, king of Sparta. Their progress was slow, as Archidamus, their commander, appears to have been still anxious to try what could be done by intimidating the Athenians before proceeding to extremities. Yet their presence was found to be a greater calamity than the people anticipated; and when Archidamus made his appearance at Acharnæ, they began loudly to demand to be led out to battle. Pericles firmly adhered to his plan of defence, and the Peloponnesians returned home. Before their departure the Athenians had sent out a fleet of one hundred sail, which was joined by fifty Corcyrean ships to waste the coasts of Peloponnesus; and towards the autumn Pericles led the whole disposable force of the city into Megaris, which he laid waste. In the same summer the Athenians expelled the inhabitants of Ægina from their island, which they colonised with Athenian settlers. In the winter there was a public funeral at Athens for those who had fallen in the war, and Pericles pronounced over them an oration, the substance of which is preserved by Thucydides (ii. 35-46).

In the following summer (B.C. 430) the Peloponnesians again invaded Attica under Archidamus, who now entirely laid aside the forbearance which he had shown the year before, and left scarcely a corner of the land unravaged. This invasion lasted forty days. In the meantime a grievous pestilence broke out in Athens, and raged with the more virulence on account of the crowded state of the city. Of this terrible visitation Thucydides, who himself was a sufferer, has left a minute and apparently faithful description (ii. 46, &c.). The murmurs of the people against Pericles were renewed, and he was compelled to call an assembly to defend his policy. He succeeded so far as to prevent any overtures for peace being made to the Lacedæmonians, but he himself was fined, though immediately afterwards he was re-elected general. While the Peloponnesians were in Attica, Pericles led a fleet to ravage the coasts of Peloponnesus. In the winter of this year Potidæa surrendered to the Athenians on favourable terms. (Thucyd., ii. 70.)

The next year (B.C. 429), instead of invading Attica, the Peloponnesians laid siege to Platæa. The brave resistance of the inhabitants forced their enemies to convert the siege into a blockade. In the same summer an invasion of Acarnania by the Ambracians and a body of Peloponnesian troops was repulsed; and a large Peloponnesian fleet, which was to have joined in the attack on Acarnania, was twice defeated by Phormion in the mouth of the Corinthian Gulf. An expedition sent by the Athenians against the revolted Chalcidian towns was defeated with great loss.

In the preceding year (B.C. 430) the Athenians had concluded an alliance with Sitalces, king of the Odrysæ, in Thrace, and Perdiccas, king of Macedon, on which occasion Sitalces had promised to aid the Athenians to subdue their revolted subjects in Chalcidice. He now collected an army of 150,000 men, with which he first invaded Macedonia, to revenge the breach of certain promises which Perdiccas had made to him the year before, and afterwards laid waste the territory of the Chalcidians and Bottiæans, but he did not attempt to reduce any of the Greek cities. About the middle of this year Pericles died.

The invasion of Attica was repeated in the next summer (428 B.C.); and immediately afterwards all Lesbos, except Methymne, revolted from the Athenians, who laid siege to Mytilene. The Mytilenæans begged aid from Sparta, which was promised, and they were admitted into the Spartan alliance. In the same winter a body of the Platæans, amounting to 220, made their escape from the besieged city in the night, and took refuge in Athens.

In the summer of 427 B.C. the Peloponnesians again invaded Attica, while they sent a fleet of forty-two galleys, under Alcidas, to the relief of Mytilene. Before the fleet arrived Mytilene had surrendered, and Alcidas, after a little delay, sailed home. In an assembly which was held at Athens to decide on the fate of the Mytilenæans, it was resolved, at the instigation of Cleon, that all the adult citizens should be put to death, and the women and children made slaves; but this barbarous decree was repealed the next day. [CLEON, in BIOG. DIV.] The land of the Lesbians (except those of Methymne) was seized, and divided among Athenian citizens, to whom the inhabitants paid a rent for the occupation of their former property. In the same summer the Platæans surrendered; they were massacred, and their city was given up to the Thebans, who razed it to the ground.

In the year 426 the Lacedæmonians were deterred from invading Attica by earthquakes. An expedition against Ætolia, under the Athenian general Demosthenes, completely failed; but afterwards Demosthenes and the Acarnanians routed the Ambracians, who nearly all perished. In the winter (426-5) the Athenians purified the island of Delos, as an acknowledgment to Apollo for the cessation of the plague.

At the beginning of the summer of 425 the Peloponnesians invaded Attica for the fifth time. At the same time the Athenians, who had long directed their thoughts towards Sicily, sent a fleet to aid the Leontini in a war with Syracuse. Demosthenes accompanied this fleet, in order to act as occasion might offer on the coast of Peloponnesus. He fortified Pylus on the coast of Messenia, the northern headland of the modern bay of Navarino. In the course of the operations which were undertaken to dislodge him, a body of Lacedæmonians, including several noble Spartans, got blockaded in the island of Sphacteria at the mouth of the bay, and were ultimately taken prisoners by Cleon and Demosthenes. [CLEON, in BIOG. DIV.] Pylus was garrisoned by a colony of Messenians, in order to annoy the Spartans. After this event the Athenians engaged in vigorous offensive operations, of which the most important was the capture of the island of Cythera by Nicias, early in B.C. 424. This summer however the Athenians suffered some reverses in Bœotia, where they lost the battle of Delium, and on the coasts of Macedonia and Thrace, where Brasidas among other exploits took Amphipolis. [BRASIDAS; THUCYDIDES, in BIOG. DIV.]

The Athenian expedition to Sicily was abandoned, after some operations of no great importance, in consequence of a general pacification of the island, which was effected through the influence of Hermocrates, a citizen of Syracuse.

In the year 423, a year's truce was concluded between Sparta and Athens, with a view to a lasting peace. Hostilities were renewed in 422, and Cleon was sent to cope with Brasidas, who had continued his operations even during the truce. A battle was fought between these generals at Amphipolis, in which the defeat of the Athenians was amply compensated by the double deliverance which they experienced in the deaths both of Cleon and Brasidas. In the following year (421) Nicias succeeded in negotiating a peace with Sparta for fifty years, the terms of which were, a mutual restitution of conquests made during the war, and the release of the prisoners taken at Sphacteria. This treaty was ratified by all the allies of Sparta, except the Bœotians, Corinthians, Eleans, and Megarians.

This peace never rested on any firm basis. It was no sooner concluded than it was discovered that Sparta had not the power to fulfil her promises, and Athens insisted on their performance. The jealousy of the other states was excited by a treaty of alliance which was concluded between Sparta and Athens immediately after the peace; and intrigues were commenced for the formation of a new confederacy with Argos at the head. An attempt was made to draw Sparta into alliance with Argos, but it failed. A similar overture subsequently made to Athens met with better success, chiefly through an artifice of Alcibiades, who was at the head of a large party hostile to the peace, and the Athenians concluded a treaty offensive and defensive with Argos, Elis, and Mantinea for 100 years (B.C. 420). [ALCIBIADES, in BIOG. DIV.] In the year 418 the Argive confederacy was broken up by their defeat at the battle of Mantinea, and a peace, and soon after an alliance, was made between Sparta and Argos. In the year 416 an expedition was undertaken by the Athenians against Melos, which had hitherto remained neutral. The Melians surrendered at discretion: all the males who had attained manhood were put to death; the women and children were made slaves; and subsequently five hundred Athenian colonists were sent to occupy the island. (Thucyd., v. 116.)

The fifty years' peace was not considered at an end, though its terms had been broken on both sides, till the year 415, when the Athenians undertook their disastrous expedition to Sicily. [ALCIBIADES, in BIOG. DIV.; SYRACUSE, in GEOG. DIV.] After the failure of that expedition (B.C. 413), the war became on the part of Athens a struggle for existence; but even then she put forth energies which might have saved her, but for her own infatuation and the gold which her enemies obtained from Persia. The events of the war, from this period to the battle of Notium (B.C. 407), have been related under ALCIBIADES, in BIOG. DIV. The Spartans had now, by the aid of Persian gold, obtained a fleet with which they could cope with Athens on her own element. In the year 406, Conon, who had been appointed, with nine other generals, to succeed Alcibiades, was blockaded in the harbour of Mytilene by the Spartan admiral Callicratidas. His colleagues sailed to his assistance, and completely defeated the Spartans in the battle of Arginusæ. The Spartans now made overtures for peace, which were rejected by the Athenians at the instigation of a demagogue named Cleophon.

In the following year (B.C. 405) Lysander was appointed to the command of the Lacedæmonian fleet. [LYSANDER in BIOG. DIV.] He attacked the Athenians at Ægospotami on the Hellespont at a moment when they were off their guard, and entirely destroyed their fleet. This blow in effect finished the war. Lysander sailed to Athens, receiving as he went the submission of the allies, and blockaded the city, which surrendered after a few months (B.C. 404), on terms dictated by Sparta with a view of making Athens a useful ally by giving the ascendancy in the state to the oligarchical party. [ATHENS, in GEOG. DIV.]

The history of the Peloponnesian War was written by Thucydides, upon whose accuracy and impartiality, as far as his narrative goes, we may place the fullest dependence. His history ends abruptly in the year 411 B.C. For the rest of the war we have to follow Xenophon and Diodorus. The value of Xenophon's history is impaired by his prejudices, and that of Diodorus by his carelessness.

PELOSINE ($C_{36}H_{21}NO_6$), *Cissampeline.* The root of the *Cissampelos pareira* contains a peculiar alkaloid, to which these names have been given. It presents the appearance of an amorphous white powder, which is inodorous, but has a sweetish bitter taste. It is insoluble in water, and possesses the same composition as codeine. When pelosine is exposed to moisture, air and light, it becomes yellow, disengages ammonia, and becomes converted into *pellutcine* ($C_{36}H_{19}NO_6$).

PEMPHIGUS is a disease of the skin, consisting of the eruption of one or more rather large blisters, containing serous fluid, and terminating either in thin scales, in superficial excoriations, or in ulceration. The common and most acute form of pemphigus is usually preceded by shivering, and accompanied by slight feverishness; the eruption appears on some part of the body from one to four days after the beginning of the illness, with a pricking sensation and bright redness of the part affected. Within 24 hours afterwards the blisters begin to rise, and increase in size till they are most frequently as large as nuts, but often much larger, and sometimes smaller. They then, after two or three days, burst, and leave the skin raw and painful. A thin scab usually forms over the exposed skin, and after a few days more, drops off and leaves it healthy, but redder, and with a thinner cuticle than natural. The treatment should consist of gentle purgatives, and cooling medicines and diet; the local applications, if any, should be mild dressings, merely for the purpose of defending the raw surfaces from the air and injury. The disease will thus usually run its course to natural recovery.

A more obstinate form is the chronic pemphigus, which occurs in old or very debilitated persons. The blisters appear one after the other, through an indefinite length of time, some breaking out while others are healing or ulcerating or even sloughing. They are so commonly the accompaniments of other more serious disorders, that the local affections of the skin in these cases are seldom the objects of peculiar treatment; if the condition of debility on which they are grafted can be relieved, they also will soon disappear.

A third form is that termed infantile or gangrenous pemphigus. It is entirely confined to children, and especially affects those who are less than five years old. It occurs sometimes as an epidemic, and is very common among the children of the poor in Ireland, where it is known under the name of white blisters, burnt-holes, eating-hive, &c. The blisters in this form are usually succeeded by deep ulcers, which enlarge rapidly and discharge profusely, and have dark livid edges and a remarkable smell. The child at the same time becomes emaciated and weak, and often about the eighth day of the disease sinks into a state of debility which soon terminates fatally.

PEN. This simple but useful little instrument was formerly made of reed; but the quill has been used in this country for the purpose for about five hundred years; and metal is now adopted still more largely.

Quill Pens.—Under FEATHERS an account is given of the mode of preparing goose-quills, up to the point where they pass to the penmaker. Of the common method of making pens by hand it is not necessary to speak; we shall therefore only say a few words upon the manufacture of "quill nibs." The barrel of the quill in the first place has both ends cut off, and is divided down the centre; the halves are then laid on their convex side and the edges shaved smooth; after this they are divided into three or four lengths each, and the end of each length is made into a pen by a small machine, which at one stroke makes the slit and cuts the shoulders; they are then finished by being nibbed by hand. Small pocket machines are sold by cutlers for making pens on the same principle as that used in the manufacture of the nibs; but they are expensive, and require careful usage, or they soon get out of order.

The pen used for German text, old English, engrossing, and other black hands as they are called, differs in make, but still more in application, from that employed for ordinary writing. The nib is made as broad as the intended thick or down stroke of the writing; and in using it no pressure is required to open the nibs, as in making a thick stroke by the common pen. The only use of the slit is to give greater elasticity to the point, and to form a channel for the ink. For very large writing two other slits are sometimes made, one in each shoulder; a pen made in this manner works more freely, and does not tire the hand so much as if made with one slit only. The fine or up strokes are produced by throwing the pen to one of the angles of its nib, generally that to the left of the hand in writing, by a turn of the wrist, and a practised hand can produce in this manner the finest hair-stroke. These pens are made of the Turkey quill, the goose quill being too weak for the purpose. In making the slit, in all quills, but more particularly in these, it is necessary that they should be well scraped, as the upper surface, being formed of fibres lying in rings around the quill, will otherwise cause the slit to be ragged.

Bone pens are now made to some extent in France; or rather bone nibs, requiring to be fixed into some kind of handle.

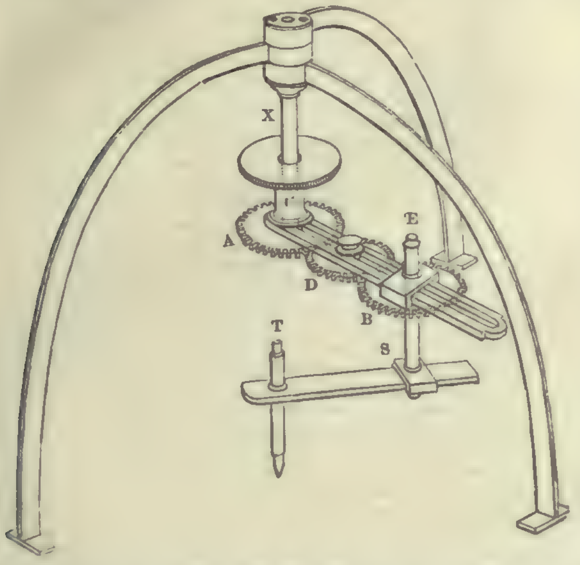
Steel Pens.—Owing to the constant necessity for mending quill pens, the loss of time consequent thereon, and the inequality of the writing, an immense amount of labour and ingenuity has been employed to produce some more durable substitute. The only one, however, which has attained to anything like general use is the steel pen. These pens are manufactured to an amount in quantity, and at a cost so small, as hardly to be credible. Different makers have different modes of operation, but the following will give a general idea of the method employed. In the first place flat pieces of steel are cut out, of the shape required, by a stamping-press; they are then placed under another press, which pierces the holes and cuts the slits; and they are struck into their convex shape by a third press. They are then polished and tempered. The polishing is managed in rather a curious manner: a quantity of pens are shut up in an iron cylinder, leaving a considerable space unoccupied; this cylinder is attached at each end to a crank, the axes of which are connected by a wheel and set in motion by a handle or by machinery. Thus by being rubbed against each other the pens come out well polished, and with all the burrs or sharp angles left by the cutting-presses rubbed smooth. It is impossible to follow with anything like accuracy the amazing spread of this manufacture. Steel pens fell in price from sixpence each to sixpence a dozen; then by degrees to sixpence a gross; and they can now be purchased at fourpence a gross, box included. Some of the largest and finest establishments in Birmingham are for the manufacture of steel pens. Before the general introduction of steel for this purpose, silver was occasionally used, when intended for presents; and brass when intended to accompany cheap brass inkstands, that were made some years ago. Sometimes quill pens were armed with metallic nibs, but this plan was not found to answer; nor was the substitution of tortoiseshell for quill much better. It has been found more practicable, although necessarily costly, to employ small fragments of precious gems for the nibs, and to imbed these in pens made of gold; the gold resists the corrosive action of the ink, while the gem will bear a large amount of work without wearing away. Diamond and ruby have been thus employed. There are also certain rare metals, especially rhodium, occasionally employed for this purpose, on account of their great hardness and durability. Gold pens with rhodium nibs are now made in the following way:—Sheet or plate gold, about $\frac{1}{32}$nd of an inch in thickness, is cut by means of a die into stubs, or small pieces, each piece having a point at one end. A machine then indents the point for the reception of the nib. Small particles of rhodium, as obtained from platinum ores, sometimes sell at prices varying from 10*l.* to 20*l.* per ounce; and one such particle is fastened to the golden point with gold solder. The gold is then rolled to the proper length and thickness, care being taken to have dents in the rollers to accommodate the hard bit of rhodium. The gold, after being hammered to give it elasticity, is cut to the proper shape with a die, stamped with the maker's name and any other device, and turned up to the rounded quill-like form. The rhodium is then split into a nib by a rapidly-revolving copper disc; and another machine extends the slit into the gold. The point is ground on a revolving copper wheel; the gold is made elastic by being rubbed with a small hard stone and water; and the finished pen is finally polished.

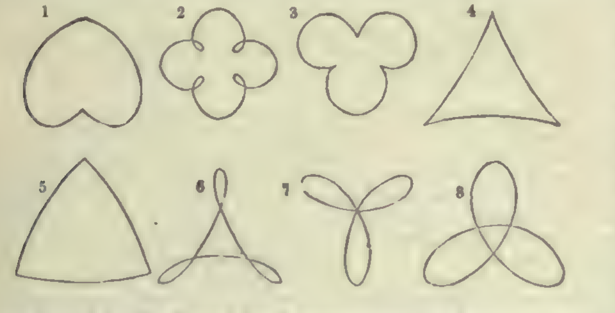
Fountain Pen is a pen made with a reservoir in its stem or holder, to supply ink for some time without replenishing. The nib is in most cases supplied by a small valve, which may be closed when not in use. The varieties are very numerous; but it cannot be said that the plan is successful, for no one variety has obtained an extensive and permanent sale.

Music Pens.—There are two kinds of pen used for the purpose of writing music; the one to rule the lines, and the other to make the dots. The former is a piece of brass with five prongs or points, in each of which is a channel for the ink, which is supplied from a small cup in the solid part of the pen just above the division of the points. The latter is a mere tube with a hole in its side for supplying it with ink, and a small wire or piston fitted within it. The ink flows between the wire and its case, and the dot is made by placing the pen upon the spot, and pressing the wire down upon the paper.

Geometric Pen.—This is an instrument invented by Suardi, an Italian, for drawing geometric curves. These curves may by combination be made to form an almost infinite variety of patterns. The pen is supported, as shown in the diagram, by three legs bowed so as to allow room for the instrument to work within them. These legs shut together by the joint at the top for the convenience of package. Attached to the joint is a stem or axis X, upon the lower end of which is fixed the toothed wheel A; this stem, with its wheel, is stationary, and all the other parts of the instrument move round it. Just above the wheel A is a small tube or cannon, C, to which is attached an arm carrying two boxes and spindles for supporting the wheels D B; the spindle E is continued downwards, and terminates in a socket S, through which passes an arm carrying the pencil or tracer, T. The two wheel boxes, D B, on the one arm, and the socket, S, on the other, may be fixed at any part of their respective arms by means of screws for that purpose. Fixed to the tube C is a small circular plate of metal with a milled edge, by which the instrument is moved around its axis by the thumb and finger.

The sort of curves produced by this instrument depends upon three circumstances: first, the relative size of the wheels A and B; second, whether the wheel D be employed or not, or in other words, whether the two arms move in directions contrary or similar to each other (this wheel has no effect otherwise, and may be of any convenient size); and third, on the relative distance of the tracer T from the spindle E, and of that spindle from the axis X, which may be expressed as the relative distance of T E and E X. The following diagram gives an idea of a few of the most simple curves. The number of parts or leaves in each figure depends on the first of the three circumstances above mentioned: for *fig.* 1 the wheels A and B must be equal; for *fig.* 2, as 4 to 1; and for the rest, as 3 to 1. On the second circumstance depends whether the loops or points are within the curve, as in *figs.* 1, 2, and 3; or on the outer side, as in the others; and lastly, upon the third circumstance depends the shape of the points or loops themselves. For the eight curves given above, T E must be less than E X; but if this is reversed, the curves assume a most curious, complicated, and sometimes beautiful arrangement.





Suardi states that 1273 curves may be produced by the changes of twelve wheels, the smallest having eight, the next sixteen, and so on to ninety-six teeth; and that by the addition of a few pieces, spirals with a circular base, and particularly the spiral of Archimedes, may be produced.

For further information the reader is referred to Suardi's work, entitled 'Nuovo Instrumento per la Descrizione di diverse Curve Antichi e Moderne,' &c.; and to Adam's 'Geometric Essays.'

PENAL-SERVITUDE. This punishment has come in place of the former punishment by *transportation*, said to have been first inflicted by stat. 39 Eliz. c. 4. The first act of parliament on this subject is the 18 Car. II. c. 3, s. 2, enabling the judge of assize to transport certain offenders to *America*, there to remain and not to return.

The 22 Car. II. c. 5, s. 4, gave the judges power, "at their discretion," to grant a reprieve, and to cause felons to be transported beyond the seas, there to remain for the space of seven years; but if the offender refused to be transported, or returned within the time, then he was to be put to execution upon the judgment. The 22 & 23 Car. II. c. 7, s. 4, directed a judgment of transportation to be entered, when the felon elected to be transported, and it authorised the sheriffs to cause offenders to be embarked. It also made a return before the expiration of the sentence, a capital felony. The next statute on the subject was the act 4 Geo. I. c. 11, "the foundation of the law of transportation," which enacted that, when the crown should be pleased to extend mercy, upon condition of transportation to any part of *America*, any court, having proper authority to do so, might direct the offender to be transported. The stat. 6 Geo. I. c. 23, again made a person "*at large* in Great Britain, before the expiration of the term" of transportation, liable, on conviction, to suffer death. The 8 Geo. III. c. 15, extended the powers of the judges to make orders for transportation by enabling them to do so out of court; and by the stat. 30 Geo. III. c. 47, the king was empowered to authorise the governors of convict settlements to remit the sentences of transports.

By the stat. 5 Geo. IV. c. 84 (amended by 11 Geo. IV. and 1 Wm. IV. c. 39), consolidating the laws on the subject of transportation, the king in council was empowered to appoint places beyond the seas, to which persons under sentence of transportation should be conveyed, the governor or other person to whom they were delivered, or his assignee, having the property in the service of the convicts. The sovereign was also empowered by warrant to appoint places of confinement at home, either on land or on board vessels in the Thames, or other rivers or harbours, for the confinement of male offenders (extended by the stat. 16 & 17 Vict. to females) under sentence of death, but reprieved or respited, or under sentence of transportation, there to remain under order of the secretary of state until entitled to their liberty, or removed, or otherwise dealt with. The capital punishment for offenders found unduly at large before the expiration of their sentence was subsequently abolished by 4 & 5 Wm. IV. c. 67, which substituted transportation for life, with previous imprisonment not exceeding four years.

New South Wales, Van Diemen's Land, and Norfolk Island, thus became the principal receptacles for convicts. Although the property in the services of these persons was vested in the colonial governor or his assigns, a practice prevailed of granting them, in certain cases and on certain conditions, permission to employ themselves for their own benefit. These permissions were usually called "tickets of leave." By the stat. 6 & 7 Vict. c. 7, the legislature, thinking it just that ticket-of-leave convicts should be protected in their persons, and in the possession of such property as they might acquire by their industry, empowered them to hold personal property, and to maintain actions in respect thereof while such tickets remained unrevoked.

The reception of convicts having, however, become distasteful to the inhabitants of the colonies, the stat. 10 & 11 Vict. c. 67, was passed, permitting offenders under sentence of transportation to be removed to any prison or penitentiary in Great Britain; directors of the principal convict prisons being appointed afterwards under the stat. 13 & 14 Vict. c. 39. The difficulty attending the reception by the colonies of transported convicts having increased, the stat. 16 & 17 Vict. c. 99, finally abolished the punishment of transportation *for less than fourteen years*, and substituted penal servitude at home for certain periods, giving the courts power in all cases to substitute such penal servitude for transportation.

Before this last statute was passed, a system had for some time prevailed with respect to well-conducted convicts (who, although sentenced to transportation, had been kept at home), of granting them free pardons, generally at the expiration of half their sentence of transportation. As the continuance of the same system under the last-mentioned statute seemed likely to cause serious evils, but as it was at the same time desirable to encourage good behaviour in convicts, it was determined to try the experiment of retaining some control over them in cases where they were set at liberty before the expiration of their original sentence. With that view the statute empowers the crown, by order of one of the secretaries of state, to grant any convict a licence or "ticket of leave," to be at large during such portion of his term of transportation or imprisonment, and upon such conditions, as may be thought fit, such licence being also revocable at pleasure.

Finally by the stat. 20 & 21 Vict. c. 3, the sentence of *transportation* is entirely abolished, and the sentence of penal servitude substituted; but the statutes which have reference to transportation are to have reference to penal servitude, so that the name alone is changed.

As to the government of convict prisons in the colonies, see 22 Vict. c. 25.

PENALTY, in its original and proper sense, is a pecuniary punishment imposed by statute upon parties guilty of certain offences. This term is also used to denote a sum of money which a party to a contract has engaged to pay in case he violates his engagement. Penalties imposed by statute are strictly regulated by statute; but with respect to penalties created by contract, the rule is neither so strict nor so uniform. The courts of law will not allow a larger sum to be recovered in the name of penalty than is sufficient to cover the damages actually sustained; but where the parties have determined in advance the damages that shall in certain events be considered to have been sustained, and nothing essentially inconsistent with the reasonableness of such determination appears upon the face of the transaction, the courts do not interfere, and the damages thus pre-determined are recoverable under the name of liquidated damages. Where a penalty is fixed, *eo nomine*, for the breach of an agreement, and yet larger damages are actually sustained, the larger amount may be recovered as damages without recourse to the penalty. In many cases the distinction between a penalty and liquidated damages is often difficult to ascertain, and some of the decisions on this head are not easily reconciled.

Formerly the interference of a court of equity was often necessary to temper the severity of the common law, but by the statute 8 & 9 Wm. III., c. 11, s. 8, it was provided that in actions in courts of record upon any bond or penal sum for the performance of covenants or agreements contained in any indenture, deed, or writing, the plaintiff shall state the breaches of covenant or agreement which he has sustained, and damages are to be assessed accordingly. If the plaintiff recover in the action, judgment is entered up for the penalty, but execution issues only for the damages assessed by the jury upon the breaches stated and proved, the judgment remaining as a security against future breaches of the same covenant or agreement, or of other covenants or agreements contained in the same instrument, and protected by the same penalty. And now there is little if any difference between the practice of the courts of common law and equity upon the subject of penalties. [Bond; Damages.]

PENANCE (in Latin, *Pœnitentia*) is a censure or punishment, enjoined by the ecclesiastical law, for the purgation or correction of the soul of an offender, in consequence of some crime of spiritual cognisance committed by him. Thus a person convicted of adultery or incest was adjudged to do penance in the church or market, bare-legged and bare-headed, in a white sheet, and was required to make a public confession of his crime, and to express his contrition in a prescribed form of words. After a judgment of penance has been pronounced, the ecclesiastical courts may, upon application by the party, take off the penance, and exchange the spiritual censures for a sum of money to be paid and applied to pious uses. This exchange is called a commutation for penance; and the money agreed or enjoined to be paid upon such a commutation may be sued for in the ecclesiastical court.

The *peine forte et dure* imposed upon a person who stands mute on his trial at the common law is often inaccurately termed penance. [Peine Forte et Dure.]

PENATES were Roman deities who were supposed to preside over families and houses. Cicero ('De Nat. Deor.,' ii. 27) derives the word either from *penus*, "food," or *penitus*, "innermost;" but it appears probable that the latter etymology is the more correct. We learn from Festus (*Penus*) that the inner part of the temple of Vesta was called Penus, which seems to be connected with *penates*, *penetrare*, and *penetralia*. The hearth of the atrium was sacred to the Penates; and as this place was the innermost or most important part of the house, it was called the Penetralia. There appears sometimes to have been a kind of recess in the wall, called *sacrarium*, in which the images of the Penates were kept. (Cic. in 'Verr.,' iv. 2; 'Dig.,' i., tit. 8, s. 9.) A fire was always kept burning on the hearth sacred to the penates; a salt-cellar dedicated to them was placed on the dinner-table, and the meal concluded with a libation to them. Every master of a family was the priest to the Penates of his own house.

It is a matter of some difficulty to determine who the Penates were; but there is no reason for believing that they were the same in every family. Some writers have thought the Lares and Penates to be the same, and it would appear that the Lares were included among the Penates. The Lares however were of human origin, and appear to have been regarded by the Romans as the manes of their ancestors [Lares]; while among the Penates we find mention of the superior gods, as Vesta, Jupiter, and Juno. (Festus, s. v. 'Herceus.')

There were also public Penates, who were supposed to have been brought by Æneas from Troy. They were represented as two young men with spears in their hands, and the temple or chapel in which they were worshipped was in the centre of the city, not far from the temple of Vesta. (Dionys., i. 68; Cic., 'De Nat. Deor.,' ii. 27; Liv., xlv. 16.)

(Hartung, *Die Religion der Römer*; Klausen, *Æneas und die Penaten*; Barker, *Lares and Penates*.)

PENCIL, the name given to the small brushes used by artists, whether made of hog's bristles, camel hair, fitch, or sable. The larger brushes are sometimes set in a tin tube, and the smaller in quills of different sizes. The soft pencils for artists are made as follows:—The tail of the animal (sable, badger, marten, &c.) is scoured in a solution of alum; then steeped for several hours in luke-warm water; then dried in linen cloths; and finally combed out regularly. The hairs are seized with pincers, and cut off near the skin; and the little parcels of hair are sorted into groups according to their length. A few hairs are then taken, enough for one pencil, and placed in a little receptacle which holds them while a thread is bound round near the roots. The base of the pencil is then trimmed flat by scissors. The hairs thus prepared are fitted either into quills or into tin tubes. The quills are those of swans, geese, ducks, lapwings, pigeons, or larks, according to the size of the pencil. Each quill is softened and swelled in hot water, and the bunch of hairs is introduced at the larger end, and pulled forward by a simple apparatus to the smaller end, where the shrinking of the quill binds the hairs closely. The great art in pencil-making is so to arrange the hairs that their ends may be made to converge to a fine point when moistened and drawn between the lips; and it is said that females are more successful than men in preparing the small and delicate pencils.

The well-known *Black-lead pencil* is made by cutting "Cumberland lead," or plumbago, into thin plates with a saw, and again into strips as wide as the plate is thick. These strips are then laid in a groove in a piece of cedar, upon which is glued another and thinner piece: the whole is afterwards rounded by a plane adapted to that purpose. Pencils are commonly marked with certain letters to denote the quality of the lead, as H for hard, B for black, M for medium, and so on. Successful attempts have been made to use black-lead powder, mixed with other substances, as a composition for pencils; it is not suitable for fine artistic purposes, but is available for common use.

Other pencils are made of black and coloured chalks for drawing, and are much more convenient than the port-crayon. Several recent kinds are described under Crayons.

The ever-pointed pencil is an instrument so simple and so well known as to require little description. The point, or nozzle, is made hollow to receive a small cylindrical piece of black lead, about three-quarters of an inch long, which cannot pass through the lower end without some little force. Within the case is a screw or worm, which, if the case be turned round with one hand while the point of the pencil is held by the other, causes a wire or mandril, about the same size as the lead, to advance or retire. When a fresh lead is put into the point, the case must be turned round towards the left until the mandril is drawn up as far as possible. The point containing the lead is then to be screwed on to the case, and the case being turned gently to the right hand, the lead must be forced forward until it can just be seen at the point. These leads are made of different degrees and sizes, and the cases are marked accordingly. The leads are manufactured in the following manner:—After the plumbago is cut into square strips of the same diameter as, or a little greater than, the lead required, they are passed successively through three ruby holes, each smaller than the preceding. By this means they are rendered perfectly round and smooth, so as to offer no impediment to the working of the pencil. Most cases are made with a reservoir at the top, in which a supply of five or six leads may be carried.

Considerable ingenuity has been displayed within the last few years in the production of these ever-pointed pencils. In some, the small rod of black lead is moved backwards and forwards by the action of a screw, as just described; in some, by a slide; and in others, by percussion. One sort is made of vulcanised india-rubber, with the end having such a nicely adjusted diameter as just to hold the lead steadily, and yet allow it to be moved by a slight percussion. Some of the best acting ever-pointed pencils are now saleable retail at sixpence each, while one particular kind is manufactured to sell retail at so low a price as twopence.

PENCIL, a term of optics, and sometimes of geometry. A pencil of rays is a collection of rays which converge to or diverge from the same point; and a pencil of lines is a number of lines which meet in one point.

PENDENT, or PENDANT, in Pointed Gothic architecture, an ornamental mass of stone, hanging down or descending from the intersections of a groined vaulting. Pendents, no doubt, originated in bosses, of which they may be considered an enlargement, and may be described as being of a corbel or bracket shape. They are in England almost peculiar to the Third Pointed or Perpendicular and the cognate domestic or collegiate style, in roofs of fan-work tracery, of which they are highly beautiful features, admitting of great variety of design. The roofs of King's College Chapel, Cambridge, St. George's, Windsor, Henry VII's Chapel, and the Divinity School, Oxford, are fine examples of the effect of pendents. Carved pendents of a different kind were frequently employed for the enrichment of open timber-roofs, but are not similarly applied, being suspended, not from the centre of the roof, but at the extremities of the hammer-beams, from which the ribs of wood-work forming the arches of the roof spring. Of this kind is the roof of the hall of Eltham Palace, and several of the halls of colleges at Oxford and Cambridge.

PENDENTIVE, though often inaccurately used as synonymous with pendent, has quite a different meaning. Strictly speaking, pendentives are the spandrels or triangular spaces between the arches or arch-headed walls, as the case may be, supporting a dome, which is continued down to the springing of such arches; consequently, where the dome rises from the cornice of a cylinder of the same diameter (as in the Pantheon at Rome), there are no pendentives, although there may happen to be arches in the cylindrical or polygonal circumference beneath the cornice. In such case the spandrels, or spaces between the arches are improperly called pendentives, notwithstanding that they sometimes are so, pendentives being those portions of the inner surface of a dome where the latter is intersected by vertical planes, whether produced by voids or solids. Pedentives are of frequent occurrence in Byzantine architecture. In London the dome of the hall or principal office of the London and Westminster bank is a pendentive one.

PENDULUM. Under Horology will be found some details respecting clock and compensated pendulums, together with figures of the *gridiron* and *mercurial* pendulums. We here insert a few miscellaneous details on the same subject.

The way in which motion is communicated to a pendulum is there described. It may be added that the clasp of the pendulum by the crutch should neither be very close nor very loose, and the axis of motion of the pendulum should be exactly in the continuation of the arbor of the crutch. The clock-frame itself must be firmly fixed, for any shake or looseness of the support of the pendulum will alter its time of oscillation: the bob should be heavy, the arc of vibration small; and when good performance is required, the rod should be of deal, well varnished or gilt. Iron-wire makes the next best rod, and brass the worst. Whenever a brass rod is used for an ordinary clock-pendulum, the maker is not master of his craft, or he thinks little of his customer's knowledge. The errors arising from changes of temperature when deal, steel-wire, and brass are used, are as 1, 3, and 5. It must however be remembered, that unless the deal rod pendulum be coated over, so as to be impervious to moisture, it will be liable to small errors arising from that cause. A range of 50° will not alter the rate of a clock with a white deal pendulum more than 5^{s} a day, if Capt. Kater's value of the expansion of deal be correct.

In a well-made clock, the error arising from expansion from temperature is the most considerable, and is that which must be guarded against. Mr. Baily's contrivance with a leaden weight is given under HOROLOGY. We may add that a lenticular form may be given to the weight, provided the proper length be preserved, and this will be an improvement, as it diminishes the resistance of the air, and the error which arises from the inertia of the air carried by the pendulum.

It is stated in the article just referred to, that in Harrison's pendulum foreign artists use zinc rods instead of brass. Zinc is objectionable as being a weak metal, and it is said by some persons to expand by jumps, which seems not very probable unless much exposed. The great objection to the gridiron pendulum is that the astronomer, if he be no workman, must rely upon the artist for perfect compensation (and this is perhaps never achieved); and again, if from rust or bad fitting the slipping parts should bind, the action will necessarily be by bounds and irregular. After the clock-maker has done his best, a year's experience will point out the error in the compensation, which can easily be remedied, if the fault be over-compensation, by cutting the zinc rods shorter. All the fixed parts should then be secured as firmly as possible by steady pins, as any attempt to reserve a power of further adjustment would be too dearly purchased by a ricketty frame. The bands attached to rods 1 and 5 for the purpose of keeping the zinc rods in their places should not squeeze the zinc, and but just press against them with the spring of the metal. Harrison is said, by Short ('Phil. Trans.,' vol. 47, p. 517), to have invented his pendulum about 1725.

The construction of Graham's pendulum allows the astronomer to alter and finally perfect the compensation. This quality, and the absence of any nice fitting or slipping parts, give Graham's construction a very decided superiority over Harrison's, especially for a clock which is not to be moved from place to place. These mercurial pendulums are generally constructed in a more expensive manner than is necessary. The vertical rods may all be made of stout steel wire, and the base and top of the stirrup of brass. Mr. Baily, in his valuable memoir ('Astron. Soc.,' vol. i.), justly recommends that the thread of the regulating screw should be deeper and coarser than it is usually made, and be tapped on a stouter cylinder. Graham's pendulum is described by himself. ('Phil. Trans.,' vol. xxxiv. p. 40.) It was invented in 1722. There are many ways of compensating a pendulum for the effects of temperature, some of which are very ingenious, and others very simple. Those described under HOROLOGY will suffice for an explanation of the principle; they are the most usual, the most easy of execution, and most exact in their operation.

The superiority of detached escapements has been noticed under HOROLOGY. In those in ordinary use, time and dirt and thickening of the oil not only affect the amount of the impulse, which is comparatively of slight moment, but the continuing action of the teeth on the pallets is also irregular. The space through which the pendulum swings, or *arc of vibration*, is thus liable to variation, which again produces a change in the time in which each oscillation is performed, that is, if the pendulum be supposed to oscillate round a fixed axis. This inequality was more apparent in the early clocks, where the pendulum was light and the arc of vibration very large, than in those of modern construction, where the pendulum is heavy and the arc small. Huyghens's remedy of cycloidal cheeks is noticed under HOROLOGY. It is said by all later writers on the subject that the remedy is worse than the disease; and it is possible enough that something like sticking between the flexible top and the cycloidal cheek may take place at the critical point, that is, just when the pendulum has arrived at the end of its swing, and is pausing for its return; and that there may be a difficulty in making and setting the cheeks so truly as to act on the pendulum in every part of its swing. A second objection is alleged against Huyghens's cheeks—namely, that, as the pendulum cannot be considered to be a heavy point suspended by a rod without weight, the centre of oscillation shifts *downwards* as the flexible portion of the top wraps on the cheek. This objection might be easily got over by making the cheeks not truly cycloidal, but of such a form that the centre of oscillation of the compound pendulum shall oscillate in a cycloid, which would be easy enough when the form of the pendulum was given. In truth this is a matter of mere speculation in astronomical clocks, for there is a much easier way of producing sensible isochronism in them, which we will describe; but we suspect that the cycloidal cheeks might still be used advantageously in clocks which resemble Huyghens's, as the Dutch clocks which are in common use.

Instead of suspending the pendulum by a perfectly flexible string, or on a knife-edge, when the motion must be in a circle, the top of the rod ends in a flat spring. (See *Figs.* 20, 21, under HOROLOGY, where the spring is seen in front, like a fine line, at the top of each pendulum.) This produces two effects upon the time of oscillation: first, by retarding the motion of the pendulum in its rise and accelerating its fall, the spring shortens the time of vibration, and the more the stronger it is; but as its action at each point is nearly proportional to the degree in which it is bent, that is, as the arc of vibration reckoned from the position of rest, this action will have no tendency to alter the isochronism of unequal arcs. The bending of the spring has however a second effect, that of causing the bob of the pendulum to describe a curve which is not circular, but which falls within a circle; and this, by proportioning the strength of the spring to the weight of the pendulum, may be made to approach to Huyghens's cycloid, or to that modification of it which we have described. It is possible to select a spring of such strength as shall completely satisfy this condition, at least within the necessary limits, that is, for such variations in the moving power as arise from dirt, thickened oil, and wear in the works.
